
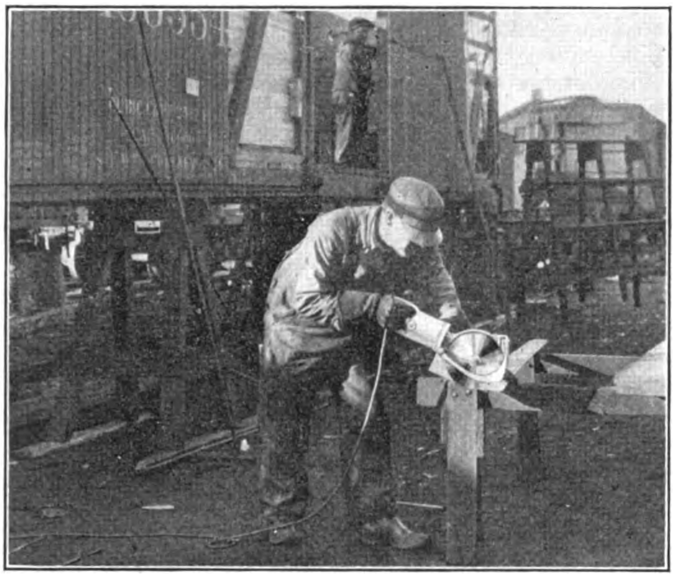
The abutment type apron permits the taking of heavy cuts

head cap screw which limits the upward travel of the gib. This brings the gib back quickly to the running position. As the parts wear the cheese-head cap screw is easily adjusted to change the running position of the gib to compensate for this wear. In cases where the operator wishes to tighten the slide merely enough to take up any tendency to move up and down while cutting, he can easily get the desired adjustment by a partial clamping of the gib. In this application the taper gib is used on a dovetail surface, but the same idea is applicable to ordinary conditions.

Portable electric circular wood saw

A PORTABLE electric circular saw adaptable to trimming car flooring and roofing and suitable for general use about a car shop or repair yard, has recently been developed by the Crowe Manufacturing Corporation, Cincinnati, Ohio.



An electric hand saw for the car man

The body of the tool is made of aluminum which makes it light in weight and easy to handle. Every part is machined and is interchangeable. The smaller size, which weighs 15 lb., has a cutting capacity, with an 8-in. blade, of 2½ in. and the larger size, which weighs 25 lb., with a 12 in. blade, will cut material 4½ in. thick.

The motor used is of the universal type, especially designed for this kind of tool. It can be supplied for either 110 or 220 volts. The saw is equipped with a trigger switch, the purpose of which is to insure safety, as the operator's finger must be held on the switch in order to keep the motor running. The motor fan and shafts are dynamically balanced in order to eliminate vibration while in operation. It is provided throughout with heavy duty ball bearings.

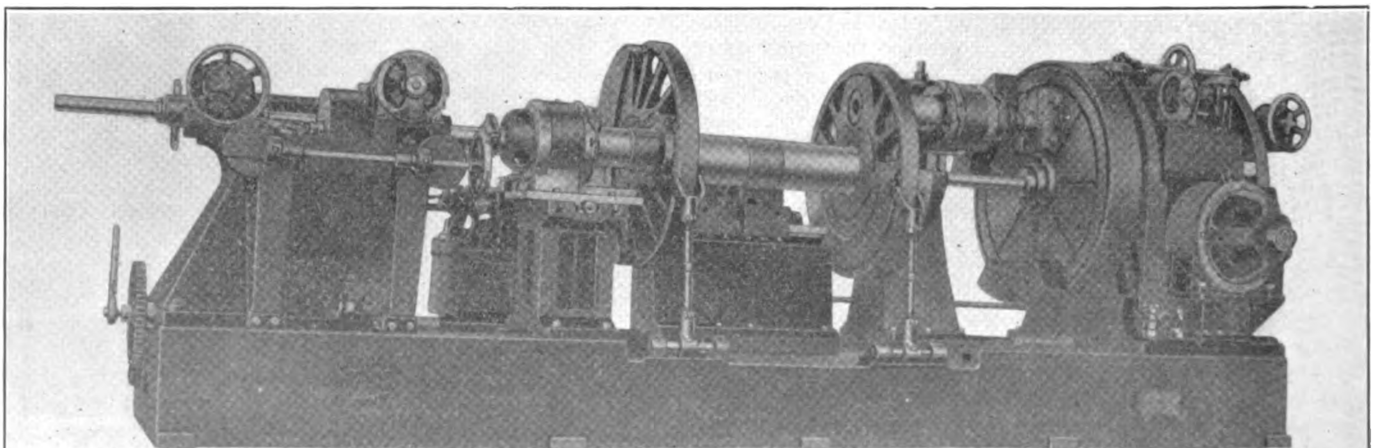
In operation, the front guide is rested flatly on the material to be cut before starting the motor. It is always advisable to keep the cutter away from the material until after the motor is started, then the saw blade is fed into the material, always keeping the finger on the trigger. After the cut is completed, the trigger is released and the tool removed for a new cut.

It is furnished with an electric light extension cord fitted with a plug which fits in any standard light socket.

Journal turning and quartering machine

THE journal turning lathe illustrated has been placed on the market by the Putnam Machine Works of Manning, Maxwell & Moore, Inc., New York, to handle wheel sets up to 86 in. in diameter on the thread. This lathe amply meets all the requirements of a machine of this type; all parts are very liberally proportioned and the various units are particularly convenient of operation.

The drive to the main spindle is by a hardened and ground worm supported on ball bearings, the worm driving a bronze worm wheel mounted directly on the spindle. Both the headstock and the tailstock are adjustable along the bed. A double carriage is mounted in a fixed position



Putnam 90-in. journal turning, quartering and crank pin turning machine, showing the crank pin turning attachment in position

for use on driver sets and a single carriage, arranged so that it may be swung around out of the way, is provided for use on trailer sets.

A faceplate of special construction is mounted on the forward end of the main spindle. The opening in the faceplate is 12 in. in diameter and of sufficient depth to accommodate the largest trailer axles. A pear shaped opening is provided into which the crank pins enter. Two independently adjustable counterweights are fitted to the face of the faceplate, each being provided with a pinion meshing with a gear ring set into the faceplate; adjustment being made by a ratchet wrench placed on the squared end of the pinion shafts. The counterweights are so arranged that any driving wheel set may be balanced and also the counterweights may be placed in balance while turning the trailer journals.

Both head and tailstocks are clamped by two large bolts on the front and two on the back, which engage T-slots in the bed. The bolts are set up by two wedges, actuated by a right and left hand screw, thus equalizing the strain on each bolt. The device is operated from either side of lathe by a ratchet wrench and quickly clamps both the head and the tailstock firmly to the bed. The adjustable spindle in the tailstock carries a ball bearing center, the headstock spindle having a live center. Therefore, no rotation takes place on the machine centers in the center holes of the axles.

The machine can be arranged for either single or double quartering with a capacity for quartering wheels of locomotives with 22 in. to 36 in. stroke.

The crank pin turning attachments are of the sleeve type, the tool slide being mounted on the end of a sleeve which completely surrounds the crank pin and revolves in a large bronze bushed bearing, thus providing rigid support for the tool. Either single or double crank pin turning attachments can be supplied if desired and can be readily removed from the machine when not in use.

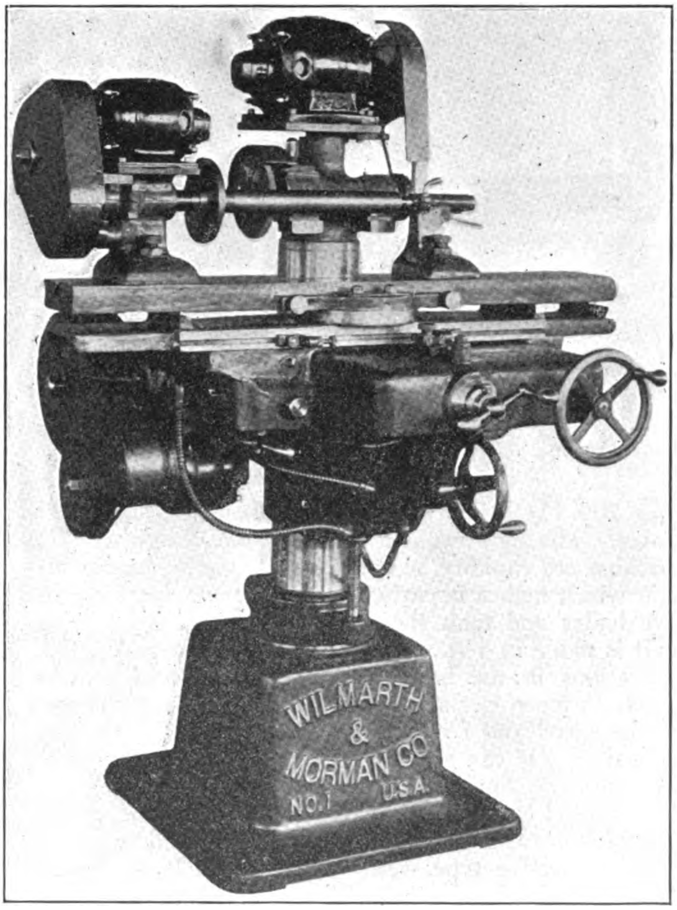
The drive can be either by a 15 hp., constant speed motor, or a 15 hp. adjustable speed direct current motor. The faceplate speeds are from 12 to 36 r.p.m. The longitudinal and cross feeds are 1/32 in., 1/16 in. and 1/8 in. for traversing the headstock and tailstock, two 5 hp., reversing, constant speed motors are required, one mounted inside the bed at each end and geared direct to the traversing screws. The quartering attachments are driven by 3 hp. motors.

Universal cutter and tool grinder

A UNIVERSAL cutter and tool grinder suitable for service in the tool room of a railroad shop has recently been placed on the market by the Wilmarth & Morman Company, Grand Rapids, Mich. The machine is motor driven and is designed for such work as facing milling cutters, grinding the blades of taper reamers, grinding cutters, hobs, etc., face and cylindrical grinding and is also provided with an attachment for internal grinding. Spindle extensions are furnished with the machine which makes it convenient to do surface grinding within the capacity of the machine.

It is mounted on a base 24 in. square, which is of sufficiently massive construction so that when the table is at its extreme position, there is no tendency for the machine to tip. The column is so mounted as to become an integral part of the base. It is ground to provide a smooth bearing for the rotation of the outer column or sleeve. The main spindle housing is carried on the top of the column which is also mounted as an integral part. Referring to the illustration, the sleeve or cutter column revolves around the inner column carrying the knee with its elevating screw. After being rotated to the desired position, it is locked by a clamp screw at the base, which draws two wedges together and against the inner column. The faces of these wedges are machined to fit the base of the column so that there is no tendency to score or wear it.

The knee is of unique construction. It has a solid top with a vertical cylindrical section which takes its bearings on the ground surface of the outer column or sleeve. To insure that the knee rises perpendicularly, a large key is mounted in the face of the sleeve and the keyway is planed in the knee. The keyway is provided with a take-up gib so that it can be tightened if wear ever causes any looseness. A dust protecting ring makes it impossible for any dust to reach the surface. The saddle carries a web or flange, 4 in. deep all the way round. This design, not only adds strength and rigidity, but aids in eliminating dust and grit from the mechanism. The saddle takes a bearing over the full top of the knee at all times and this bearing is provided with an adjustable gib. The saddle



A universal cutter and tool grinder provided with front and rear controls

bearing for the sub-table is 28 in. long and is provided with a taper take-up gib so that it is easy to maintain.

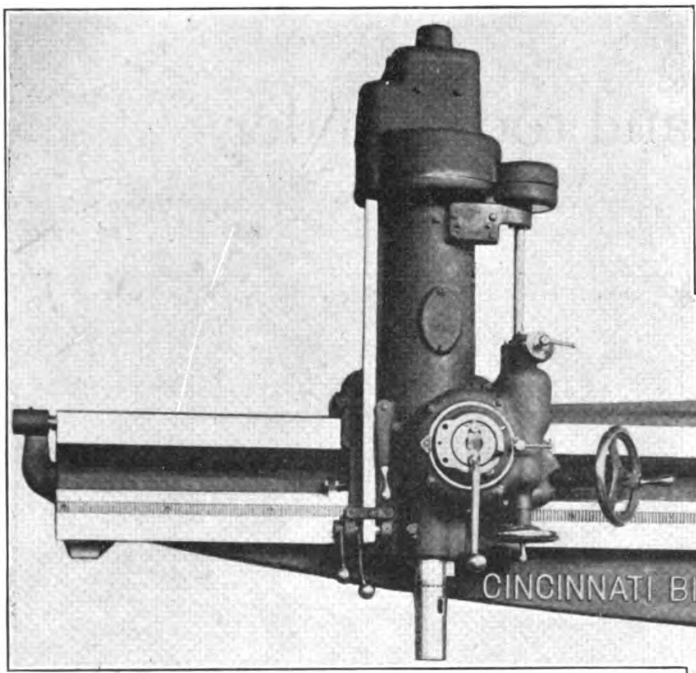
The table and sub-table are heavily ribbed castings, the sub-table being supported in the saddle bearing while the table is supported by the sub-table near the ends. It has one central T-slot.

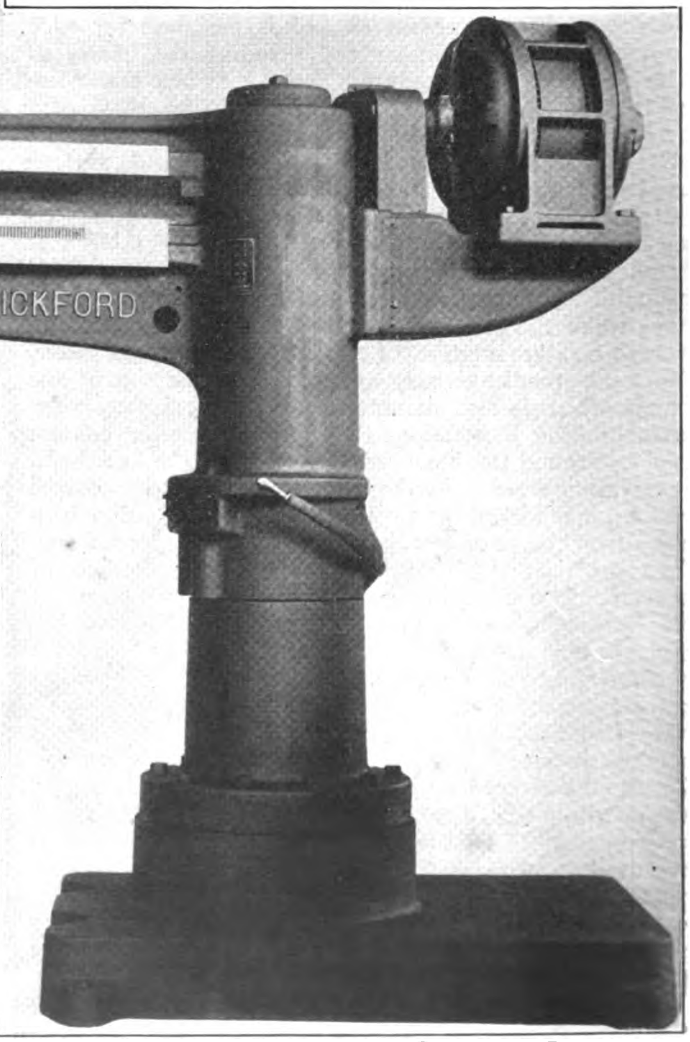
The longitudinal movement of the table can be operated by either the large hand wheel located at the front of the saddle, or by a lever handle at the rear which imparts a quick travel to the table. Suitable means are provided in both the hand wheel and feed lever for disengaging them, thereby permitting independent operation by the front or rear of the table or by power feed. The cross feed is operated by the ball crank handle on the front of the saddle or by the ball crank handle at the side.

From the description just given, it will be noted that the workman can operate the cross feed, longitudinal feed and vertical movement, without having to change his position in front of the machine. This arrangement is especially convenient when grinding cylindrical work or surface grinding. The additional feature of rear control of all movements gives the operator an opportunity to observe the cutting action of the wheel on the work from the back of the machine.

Heavy type plate and rivet hole driller

A HEAVY plate and rivet hole drilling machine has recently been placed on the market by the Cincinnati-Bickford Tool Company, Cincinnati, Ohio. It is claimed that with this machine one operator can drill over 700 11/16-in. rivet holes per hour through steel plates. The most salient points in the design of this machine are rapidity, simplicity and ease of manipulation which makes it particularly adaptable for locomotive boiler and tank shop work.





Heavy type plate and rivet hole driller provided with a special left hand arm

It is made in 4-ft., 5-ft., 6-ft. and 7-ft. arm lengths. Variations in the base mounting and special attachments to meet special requirements, as well as changes in the speed and feed can be adapted to this machine, if desired. It can also be supplied with a special left-hand arm as shown in one of the illustrations.

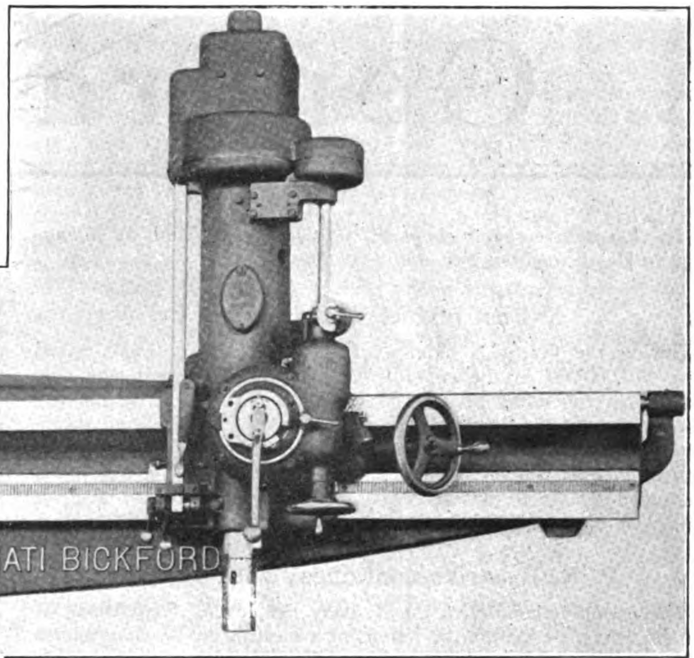
The head contains a quadruple gear shift, the speeds to which are transmitted to hardened steel sliding gear of the selective type. Any speed desired can be instantly obtained by means of levers placed on the lower left side of the head convenient to the operator. The mechanism is fully enclosed and a direct reading dial depth gage and safety stops are provided. The head is gibbed to narrow guides and is well balanced, which affords an easy longitudinal traverse on the frame. It can be clamped without disturbing the attachment for the gib.

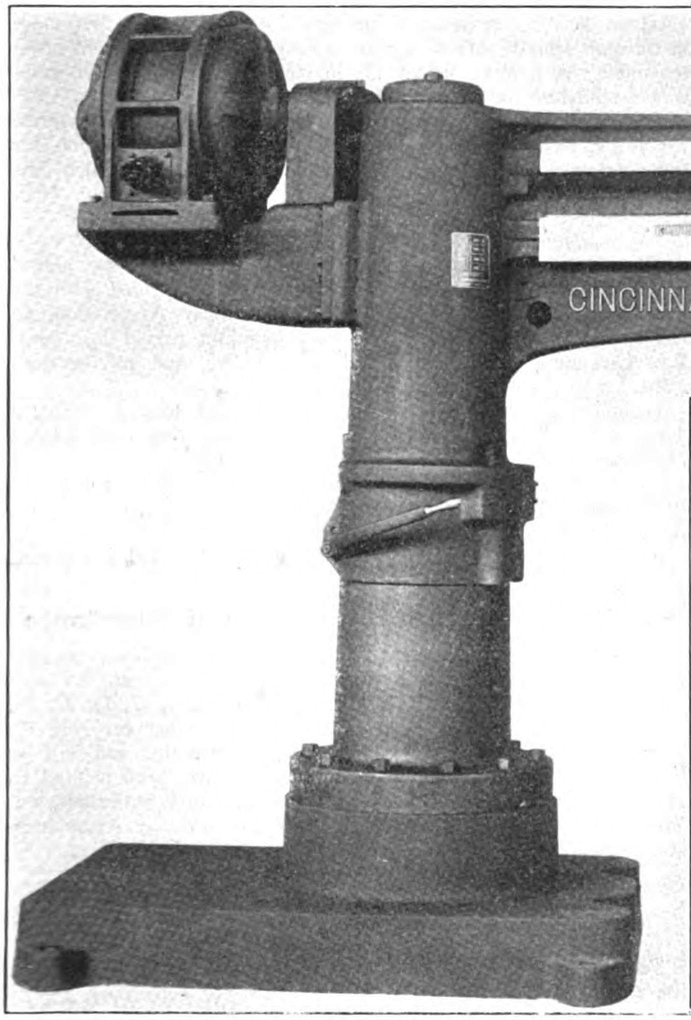
The bearing for the spindle sleeve is lapped with cast iron laps. The spindle is made of heat treated alloy steel. This type of spindle was adopted to provide protection for the Morse taper as well as the drift slot in the spindle nose. It is double splined and is provided with both hand and feed rapid advance and return. A long detachable lever can be supplied for special hand feed for use in countersinking holes.

The arm is made in a box section, a design which affords a considerable degree of stiffness. The narrow guide-way is designed to eliminate all possibility of the head rocking sideways. Although the arm is of massive

construction, it can be easily swung in either direction by the operator. The motor is mounted on an extension of the arm behind the column.

The column clamp has a large clamping area for holding the arm and column. This construction prevents any movement of the arm when it is clamped which facilitates the spotting for holes and assists the operator in obtaining maximum production with the



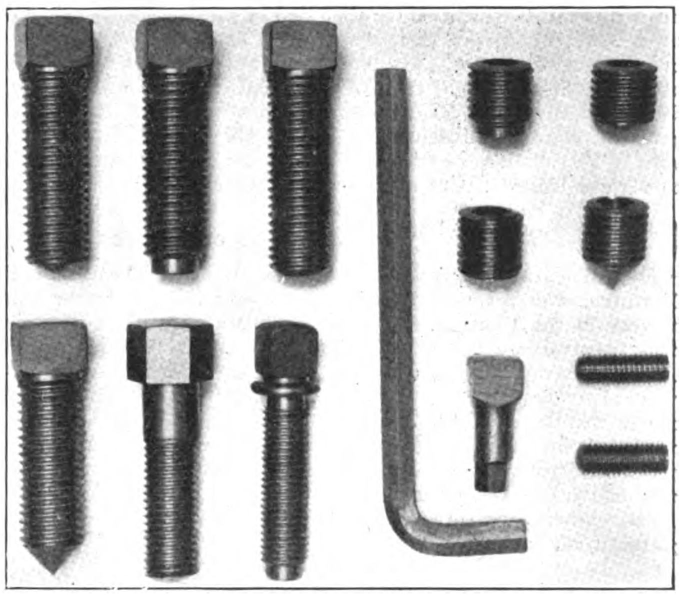


Motor driven drill press with base mountings and special attachments arranged to meet work requirements in the railroad shops

machine under the usual working conditions encountered in locomotive boiler shop work.

Set screws for use on eccentric rods

THE illustration shows a number of square head, hexagon head and hollow set screws that have been designed to provide set screws of considerable torsional strength as well as ability to stand upsetting on the point. These set screws are said to have undergone a number of severe tests before being placed on the market. One of the tests to which the square and hexagon head set screws were subjected was to screw them down into a steel block that had been tapped about two-thirds of the way through. The set screw was then screwed into the block until either the set screw or block failed. In one of these tests the bottom of the hole was pushed out and the other tests resulted in fracturing the block. These screws were also given tension and compression tests. In the case of the hollow set screws, a block of steel was drilled and tapped through and the two screws were tightened against each other by placing one wrench in a vice and tightening the other screw down until either one of the screws or the block



Various styles of square and hexagon head and hollow set screws manufactured by Warren, Killion & Clark

failed. In this test also the block was fractured. These severe tests are made possible by the fact that the set screws are made from a special steel and treated according to a special process. This line of set screws is manufactured by the Warren, Killion & Clark Company, Inc., New York.

THE NEW YORK CENTRAL about April 1, inaugurated the practice of running its passenger locomotives through between Chicago and Buffalo in both directions without change. This run, over a distance of 520 miles, is one of the longest, if not the longest, established with coal burning locomotives.

General News

The locomotive repair shops of the Chicago & Alton at Bloomington, Ill., have been closed for 60 days.

Cost of fuel in February

During the first two months of this year the railroads saved over $10,000,000 in the cost of fuel as compared with the cost for the corresponding period of last year, according to the monthly statement compiled by the Interstate Commerce Commission showing the amount and cost of fuel for road locomotives charged to operating expenses for Class I roads. In February the roads consumed 8,008,539 tons of coal, at an average cost of $2.81 a ton, or a total of $22,501,412, as compared with 9,040,988 tons.

P. R. R. strike continues "with vigor"

The executive counsel of the Railway Employees' Department of the American Federation of Labor, at a meeting in Washington on May 12 and 13, adopted resolutions soliciting "the largest possible support and co-operation of all those who are opposed to industrial tyranny," in behalf of the membership of the six shop crafts formerly employed on the Pennsylvania, whose strike, which began on July 1, 1922, is said to be "continuing with full vigor."

Cars and engines inspected in April

The Bureau of Locomotive Inspection of the Interstate Commerce Commission inspected 6,635 locomotives during April, according to the monthly report of the Interstate Commerce Commission to the President on the condition of railroad equipment. Of these 3,030, or 46 per cent, were found defective and 291 were ordered out of service. The Bureau of Safety during the month inspected 101,037 freight cars, of which 3,002, or 3 per cent, were found defective, and 2,475 passenger cars, of which 23, or 0.9 per cent, were found defective. During the month 12 cases, involving 21 violations of the safety appliance acts, were transmitted to various United States attorneys for prosecution.

A. T. & N. pays bonus to employees

John T. Cochrane, president of the Alabama, Tennessee & Northern, who promised a year ago to give bonuses to the employees in the three principal departments of the road, if each department should show for one year as favorable a percentage of expenses to earnings as in the year then closing, recently announced to the men that the bonus had been earned. This is for the 12 months ending with April, and was payable to men who continued in the service throughout the year. In the transportation department the beneficiaries were the enginemen, trainmen and hostlers; in the mechanical department, all mechanics, boiler washers, apprentices and pumpers; and in the roadway department, all foremen and assistant foremen.

Wage statistics for February

The number of employees reported by Class I railroads for February, 1925, was 1,725,366, a decrease of 2,967, or 0.2 per cent from the number reported for the previous month, according to the Interstate Commerce Commission's monthly bulletin of wage statistics. The total compensation decreased $19,488,816 or 8.0 per cent. This large decrease in compensation is due principally to the fact that there were only 23 working days in February, while January had 26. Compared with the returns for the same month last year, the employment shows a decrease of 1.6 per cent and the total compensation a decrease of 3.1 per cent. There was one more working day in February, 1924, than in February, 1925.

Gulf, Mobile & Northern awards fuel contest prize

The April fuel handicap was the most successful fuel contest ever held by the Gulf, Mobile & Northern. Engineer Frank Armour and Fireman W. J. Johnson on an eight-wheel passenger locomotive took first place in passenger service, using 1,340 lb. of coal per 100 passenger car-miles. Engineer J. E. Stephens and Fireman J. T. Metcalf on a Decapod locomotive took first place in through freight service, using 90 lb. of coal per thousand gross ton-miles. A new record of 122 lb. per thousand gross ton-miles was established for all freight service including locals, and 1,535 lb. per 100 passenger car-miles was established in passenger service for the month. Based on the business and the consumption for the previous month, the company saved over a car of coal a day.

New equipment

Class I railroads during the first three months this year placed in service 44,163 freight cars, according to reports filed with the Car Service Division of the American Railway Association, an increase of 6,511 cars over the corresponding period last year. Box cars numbered 22,665; coal cars, 15,995, and refrigerators 2,384.

Freight cars on order on April 1 this year totaled 46,126, a decrease of 23,172 from 1924. Of these, the box cars totaled 24,434; coal cars, 16,482, and refrigerators 1,933.

Locomotives placed in service during the first three months in 1925 numbered 430, a decrease of 231. Locomotives on order on April 1, 1925, totaled 315 compared with 520.

All of these figures include new, rebuilt and leased equipment.

Supplement published to the Rules of Interchange

A supplement to the current Rules of Interchange has been prepared by the Arbitration Committee of the American Railway Association containing interpretations of rules, 2, 4, 17, 18, 32, 36, 43, 87, 91, 98, 101, 104, 107 and 112, and passenger car rule 10. These supplements are now available for distribution and will be supplied on requisition. A sufficient quantity has been printed to supply one copy for each copy of the Interchange Rules printed. The prices to the members of the American Railway Association are as follows:

100 copies, or more, per hundred	$1.50
50 copies	1.00
Less than 50 copies, each	.03

To other than members of the American Railway Association, the supplements will be sold at six cents per copy. All remittances should be made payable to the American Railway Association, Chicago.

Court News

Charges against former railway shop crafts employees of contempt of court for violation of the injunction against violence in the shopmen's strike in 1922 were dismissed by Federal Judge Claude V. Luse at Superior, Wis., on May 8, according to press reports from that city. The injunction, which was alleged to have been violated, was granted the Chicago, St. Paul, Minneapolis & Omaha on July 20, 1922.

Safety appliance act held not to apply to car inspectors.—The Texas Court of Civil Appeals holds that, while the alinement of a drawhead preparatory to impact is a part of the act of coupling within the federal Safety Appliance Act, the act does not require drawbars to be kept in perfect alinement at all times. They must have some freedom of action to negotiate curves. The statutory duty is to keep them in such alinement and so equipped that they will couple automatically without the necessity of anyone going between the ends of the cars.

It is also held that a car inspector, whose duty it is to discover and repair defects in couplings, cannot recover under the federal act for injuries received in the course of his employment. This appears to be the first case in which the question of the application of the act to car inspectors has been passed upon.—K. C. M. & O. (Tex. Civ. App.), 262 S. W. 520.

Labor Board decisions

Demotion of carpenter foreman not covered by agreement.—A carpenter foreman on the New York, New Haven & Hartford, after three years' service as carpenter and 10 years as carpenter foreman, was demoted and his position assigned to another man, his junior in the service. The explanation offered was that his successor, while employed as a substitute during a vacation period, had demonstrated greater ability as a foreman in that his time books showed a better labor production. This position was contested by the United Brotherhood of Maintenance of Way Employees and Railway Shop Laborers, who contended that the action of the railroad was a discrimination and violation of seniority rights; and after unsatisfactory hearings with the railroads, carried the case before the Labor Board. The carrier's position was that the agreement with the brotherhood nowise covered foremen and contained no provision relating to the working conditions of the foremen. The decision of the board is that in the absence of any rule in the existing agreement governing the case the claim of the employees is denied.—*Decision No.* 3116.

Effect of type of engine on hostlers' compensation.—The Railroad Labor Board has decided that hostlers operating a small standard engine, which was rebuilt with the tank on top of the boiler and the coal space an integral part of the locomotive, used in switching and shifting engines at the roundhouses of the Missouri-Kansas-Texas at Parsons, Kans., shall be paid the engineers' rate for such service. The Labor Board denied the contention of the employees that two days' pay for each day of service is required in view of their contention that the engine is a shop-yard engine and that when hostlers are used to operate it during the course of their assignment as hostlers, they are entitled to not less than a minimum day as a hostler and in addition a minimum day as switch engineer under the engineers' contract. The management contended that the engines could not properly be regarded as yard engines. The management also contended that the shifting, handling and moving of engines in and about the roundhouse and roundhouse zone is work properly coming within the scope of employment of hostlers, that it is wholly immaterial what class of engine is used in the handling of such work.—*Decision No.* 3171.

Shop crafts co-operative plan to be tried on the North Western

A plan for the co-operation of its shops, similar to that first tried on the Baltimore & Ohio, has been approved in an agreement between the Chicago & North Western and the Federated Shop Crafts. The C. & N. W. is the fourth railway to try the experiment, the Canadian National and the Chespeake & Ohio having recently undertaken it.

Under the plan the management and the union agree to co-operate to improve service to the public, to share together any consequent benefit, and to perfect a definite administrative machinery to accomplish these purposes. The agreement reads in part:

"Aside from our mutual interest in the prosperity of the railway, one of the foremost benefits to the employees lies in the stability of employment, and the management is equally interested in the constant and efficient use of its shop facilities. Employees can without doubt bring to the attention of the management many points which will improve local conditions as to methods of planning and handling work in shops and roundhouses on Sundays and holidays and also promotion and co-operative attention to the welfare of the employees. These factors together with the economical use of time and forces, use of tools of the railway in the most advantageous manner, and performance of work by the minimum number of employees consistent with the various classes of work available will aid in the successful operation of the shops and repair facilities."

Conferences are to be held at local points where foremen and other local officers will meet with shop committeemen. It is expected that the first meeting will be held in the shops at Clinton, Iowa. The meetings are to be held on company time with the ranking officer of the railway or his representative acting as chairman of the joint committee. Subjects suggested for consideration are co-operation between departments; proper distribution, storage, and care of materials; increasing efficiency of tools and machines; disposition of scrap; most efficient method of handling engines through the shops; reclamation of usable material; condition of shops and shop grounds and arrangement of car repair tracks and tools. O. S. Beyer, Jr., consulting engineer of the Federated Shop Crafts, who assisted in the inauguration of the plan on the Baltimore & Ohio, will act in a consulting capacity to the union in the operation of the plan on the North Western.

Meetings and Conventions

Annual meeting of the A. S. T. M.

The annual meeting of the American Society for Testing Materials will be held June 23-26 at the Hotel Chalfonte-Haddon Hall, Atlantic City, N. J. Committee meetings will be held on Monday and Tuesday, the regular program opening on the evening of the latter day. The program includes double sessions on the last three days. The day's sessions and subjects are as follows: Tuesday, wrought iron, cast iron and corrosion; Wednesday, nonferrous metals, metallography, ceramics, coal, timber, rubber, slate, presidential address and reports of administrative committees; Thursday, steel and fatigue of metals, road materials, waterproofing, roofing materials, research, testing, nomenclature and specifications; and Friday, paints, textiles, petroleum products, insulating material, cement, lime, gypsum and concrete.

A. S. M. E. nominations

The Nominating Committee of the American Society of Mechanical Engineers at its recent meeting at Milwaukee, Wis., nominated the following officers for the next calendar year: President, William L. Abbott, chief operating engineer, Commonwealth Edison Company, Chicago. Vice-Presidents, A. G. Christie, professor of mechanical engineering, Johns Hopkins Uni-

versity, Baltimore, Md.; William T. Magruder, professor of mechanical engineering, Ohio State University, Columbus, Ohio; Roy V. Wright, managing editor, Railway Age, and editor, *Railway Mechanical Engineer*, New York. Managers, Robert L. Daugherty, professor of mechanical ard hydraulic engineering, California Institute of Technology, Pasadena, Cal.; William Elmer, superintendent, Middle division, Pennsylvania Railroad Company, Altoona, Pa.; Charles E. Gorton, chairman, American Uniform Boiler Law Society, New York. Treasurer, Erik Oberg, editor, Machinery, New York.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs.

AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

AMERICAN RAILWAY ASSOCIATION, DIVISION V.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Business meeting to be held in Chicago, June 16, 17 and 18. No exhibit of railway supplies and machinery will be held.
DIVISION V.—EQUIPMENT PAINTING SECTION.—V. R. Hawthorne, Chicago. Next meeting September, 1925.
DIVISION VI.—PURCHASES AND STORES.—W. J. Farrell, 30 Vesey St., New York.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—G. G. Macina, 11402 Calumet Ave., Chicago. Annual convention August, 1925, Hotel Sherman, Chicago.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Railroad Division. A. F. Steubing, Bradford Corp., 25 West Forty-third Street, New York.

AMERICAN SOCIETY FOR STEEL TREATING.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio. Annual convention week of September 14, 1925, Cleveland, Ohio.

AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, 1315 Spruce St., Philadelphia, Pa. Annual meeting, June 23-26, Chalfonte-Haddon Hall, Atlantic City, N. J.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago, Ill. Annual meeting October 27 to 30, inclusive, Hotel Sherman, Chicago.

CANADIAN RAILWAY CLUB.—C. R. Crook, 129 Charron St., Montreal, Que. Regular meetings second Tuesday in each month, except June, July and August, at Windsor Hotel, Montreal, Que.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 N. Pine Ave., Chicago, Ill. Meeting second Monday in month, except June, July and August, Great Northern Hotel, Chicago, Ill.

CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—R. E. Giger, 721 North 23rd street, E. St. Louis, Ill. Meetings, first Tuesday in month, except June, July and August, at the American Hotel Annex, St. Louis.

CENTRAL RAILWAY CLUB.—H. D. Vought, 26 Cortlandt Street, New York, N. Y. Regular meetings second Thursday each month, Hotel Statler, Buffalo, N. Y.

CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—A. S. Sternberg, Belt Railway, Clearing Station, Chicago. Annual convention Hotel Sherman, Chicago, September 22-24.

CINCINNATI RAILWAY CLUB.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meetings second Tuesday, February, May, September and November.

CLEVELAND STEAM RAILWAY CLUB.—F. L. Frericks, 14416 Adler Ave., Cleveland, Ohio. Meeting first Monday each month except July, August and September, at Hotel Cleveland, Public Square, Cleveland.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—W. J. Mayer, Michigan Central, 2347 Clark Ave., Detroit, Mich. Next convention, Hotel Winton, Cleveland, Ohio, August 18, 19 and 20.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. B. Hutchinson, 6000 Michigan Ave., Chicago, Ill.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Annual convention September 8-11, Hotel Sherman, Chicago.

MASTER BOILER MAKERS' ASSOCIATION.—Harry D. Vought, 26 Cortlandt St., New York, N. Y.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meeting second Tuesday in month, except June, July, August and September. Copley-Plaza Hotel, Boston, Mass.

NEW YORK RAILROAD CLUB.—H. D. Vought, 26 Cortlandt St., New York. Meeting third Friday each month, except June, July and August at 29 West Thirty-ninth Street, New York.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgreb, 623 Brisbane Building, Buffalo, N. Y. Regular meetings, January, March, May, September and October.

PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Regular meetings second Thursday of each month in San Francisco and Oakland, Cal., alternately.

RAILWAY CLUB OF GREENVILLE.—F. D. Castor, clerk, maintenance of way department, Bessemer & Lake Erie, Greenville, Pa. Meeting last Friday of each month, except June, July and August.

RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Regular meeting fourth Thursday in month, except June, July and August. Fort Pitt Hotel, Pittsburgh, Pa.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings second Friday in each month, except June, July and August.

SOUTHEASTERN CARMEN'S INTERCHANGE ASSOCIATION.—J. E. Rubley, Southern railway shops, Atlanta, Ga.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, 1177 East Ninety-eighth Street, Cleveland, Ohio. Annual meeting September 15-18, 1925, Chicago.

WESTERN RAILWAY CLUB.—Bruce V. Crandall, 189 West Madison Street, Chicago. Regular meetings third Monday in each month, except June, July and August.

Supply Trade Notes

The General Piston Ring Company, Indianapolis, Ind., has moved its plant and offices to Tipton, Ind.

The Chicago Pneumatic Tool Company will construct a one-story addition to its plant at Los Angeles, Cal.

The Symington Company has removed its New York office from the Woolworth building to 250 Park avenue.

The Sellers Manufacturing Company, Chicago, will construct a one-story rolling mill 85 ft. by 160 ft. to cost $30,000.

C. F. Moore has been appointed manager of railroad sales of Berry Bros., Detroit, Mich., to succeed E. F. Fisher, resigned.

The Nathan Manufacturing Company has removed its executive offices from 21 East Fortieth street to 250 Park avenue, New York City.

The Standard Steel Car Company and subsidiary companies have removed their offices from 170 Broadway to 120 Broadway, New York City.

The Browning Crane Company is the new name adopted by the Browning Company, Cleveland, Ohio, makers of locomotive cranes and buckets.

C. B. Semple, 104 South Michigan avenue, Chicago, has been appointed Chicago representative of the C. H. Whall Company, Boston, Mass.

The office of William H. Keller, Inc., has been removed from 50 Church street to 54 Dey street, New York City. A. B. Inness is district manager.

The Pennsylvania Car Company plans the construction of a structual steel fabricating unit at its plant at Beaumont, Tex., to cost approximately $90,000.

The Atlas Steel Casting Company, Buffalo, N. Y., has removed its New York sales office from 200 Fifth avenue to 30 East Forty-second street, New York City.

The Harnischfeger Corporation, Milwaukee, Wis., has opened a branch office at 431 First National Bank building, Birmingham, Ala., in charge of James Van Buskirk, who has been transferred from the company's office at Detroit, Mich.

J. L. Price, vice-president and treasurer of the Chicago Pneumatic Tool Company, has been appointed vice-president and general manager of the newly organized Bendix Corporation, Chicago, and president and general manager of the Bendix Brake Company, South Bend, Ind., a subsidiary of the Bendix Corporation.

A. A. Boschert has been appointed sales engineer of the Harnischfeger Corporation, with headquarters at Seattle, Wash., to cover Washington and Oregon. The company has prepared plans for a one-story brick and steel addition, 60 ft. by 88 ft., to the core room of its electric steel foundry in Bay View, Wis.

The Coplan Steel Corporation, Inc., Ogdensburg, N. Y., has completed its plant at Ogdensburg, and is now on a production basis for the supply of chromatic heat resisting steel grate bars. A. H. Coplan is president and Godwin Shenton, vice-president, Ogdensburg. J. H. Burwell, 2708 Grand Central Terminal, is the New York representative.

Charles S. Durkee has been appointed western district sales manager in charge of the sale of stock products in the west and southwest, of J. H. Williams & Co., Buffalo, with headquarters at 117 N. Jefferson street, Chicago, Ill. Mr. Durkee has been with the Williams organization for 18 years and for the past two years was in charge of the central sales district, with headquarters at Buffalo.

Joseph M. Brown, formerly representing the W. F. Hebard Company, Chicago, has entered the sales organization of the Chicago Malleable Castings Company, Chicago, and will be engaged in the promotion of general sales. Guy Bishop, formerly sales representative of the Waugh Equipment Company, has been appointed sales representative of the Chicago Malleable Castings Company, Chicago.

Russell F. Kleinman, Land Title building, Philadelphia, Pa., has been appointed sales representative of the Scott Valve Manufacturing Company, Detroit, Mich. Mr. Kleinman will handle the company's line of valves in Eastern Pennsylvania, Southern New Jersey, Maryland, Delaware and the District of Columbia. The Charles H. Tinker Company, 201 Devonshire street, Boston, Mass., has been appointed New England representative.

An engineering research department to study the requirements for automatic control and other problems in various industries, and an experimental department have been created by the C. J. Tagliabue Manufacturing Company, Brooklyn, N. Y. Victor Wichum, chief engineer, is in charge of the engineering research department, and Frank Bast continues in charge of development work on indicating, recording and controlling instruments. R. M. Wilhelm, formerly of the Bureau of Standards, is in charge of the development of oil-testing instruments. Daniel C. Day is working on some of the more important problems of the users of TAG instruments, under Harvey D. Cooke, general sales manager. William C. Begeebing is in charge of automatic controllers, dial indicating and recording thermometers.

Joseph J. McGarrigle has been appointed eastern manager of the Clark Car Company, succeeding B. K. Mould, resigned. His headquarters are at 52 Vanderbilt avenue, New York City. Mr. McGarrigle graduated in civil and structural engineering from the Pennsylvania State College in the class of 1914. He served in the engineering department of the American Bridge Company until 1916, and then entered the engineering department of the Department of City Transit, Philadelphia, Pa. Mr. McGarrigle served as first lieutenant in the United States Army from July, 1917, until he went to the Midvale Steel & Ordnance Company, car department, general sales, Philadelphia, Pa., in 1919, and when it was merged with the Bethlehem Steel Company he remained in the same department until the time of his joining the Clark Car Company on November 1, 1924.

C. P. Wright, assistant vice-president of the American Brake Shoe & Foundry Company at Chicago, has been promoted to vice-president, with the same headquarters. Mr. Wright was born in Garrett, Ind., on September 12, 1880, and after graduating from high school entered railway service with the Baltimore & Ohio. A year later he entered the employ of the Ansonia Clock Company in Chicago and later the employ of the Chicago Grain Door Company, with the same headquarters. On August 1, 1900, he entered the employ of the Featherstone Foundry & Machine Company, which was absorbed by the American Brake Shoe & Foundry Company. During the past 7 years of his employ with the American Brake Shoe & Foundry Company he has been assistant to the vice-president and assistant vice-president at Chicago.

C. P. Wright

George M. Hogan, secretary and general sales agent of the Sellers Manufacturing Company, with headquarters in Chicago, has been promoted to vice-president, with the same headquarters. He was born in Chicago on October 9, 1883, and received his education in St. Ignatius College, Chicago. He entered the employ of the Sellers Manufacturing Company on August 20, 1906, as a shipping clerk in the plant in Maywood, Ill. He held several positions in the operating and accounting departments in the plant until October 1, 1912, when he entered the sales department as sales agent, with headquarters in Chicago. He held the latter position until April, 1917, when he was promoted to general sales agent, which position he held until January 1, 1918, when he was appointed assistant secretary and general sales agent, with the same headquarters. In February, 1919, he was promoted to secretary and general sales agent.

Trade Publications

PUNCH RIVETERS.—Bulletin R-203, illustrating and describing Hanna rapid punch riveters, has been issued by the Hanna Engineering Works, Chicago.

JACKS.—A safety suggestion concerning all types of double-acting tripping track jacks has been issued in bulletin form by Templeton, Kenly & Co., Ltd., Chicago, Ill.

GRINDING MACHINES.—A few typical jobs as handled by the Heald railroad internal grinder are shown in the pages of a 20-page pamphlet, Bulletin No. 522, issued by the Heald Machine Company, Worcester, Mass.

RIVETERS.—Hanna bull riveters, which are built in sizes ranging from 4 in. to 21 ft. reach, and in capacities from 6 to 150 tons, are described and illustrated in a 36-page bulletin, R-204, recently issued by the Hanna Engineering Works, Chicago.

FLEXIBLE COUPLINGS.—Bulletin No. 35 descriptive of Falk-Bibby flexible couplings has been issued by the Falk Corporation, Milwaukee, Wis. The couplings, designed for every purpose, range in speed from 1/3 to 20,000 h. p. at 100 r. p. m.

ASCO BULLETINS.—"Do your men really know what end ladder clearance is and how to measure it?" is the title of Bulletin No. 4, and "How much money are you losing through non-observance of A. R. A. Rule 86, paragraph 'd'?" are the titles of Bulletins No. 4 and 5 which have recently been issued by the Allegheny Steel Company, Brackenridge, Pa.

BRIDGEPORT PRODUCTS.—Tabulated data, giving the weights, sizes and lengths of Bridgeport products, including brass and copper sheet, rod, wire and shapes, tubing, piping and fabricated articles, are contained in a 48-page booklet, No. 16, which has been issued by the Bridgeport Brass Company, Bridgeport, Conn. Price lists, conversion tables, etc., are also included in the booklet.

TURRET LATHES.—Practical methods for producing turned parts in lots of five to fifteen pieces by the use of machines with standard adjustable tools, are outlined in a 12-page circular, entitled "Profits from small lot production," which has been issued by the Warner & Swasey Company, Cleveland, Ohio. Illustrations show the main points in set-up, and set-up times from actual jobs are given.

FORGED STEEL PIPE FLANGES.—An attractive catalogue of 86 pages, the purpose of which is to place before those who use or specify flanges a complete list of standard forged steel flanges, together with data, descriptions and other information helpful in connection with high pressure piping layouts or pipe fabrications, has been issued by the American Spiral Pipe Works, Chicago. Formulas and data tables embody the new American Engineering standards of 400, 600 and 900 lb. W. S. P., and cover also the existing standards. Full-size cross-sectional drawings show modern practice in the field of increasing pressures and superheat. A section of the catalogue is also devoted to corrugated steel furnaces.

PYROMETERS.—A 56-page catalogue descriptive of indicating, portable and recording pyrometers has been issued by the Republic Flow Meters Company, Chicago. The equipment and methods used in the manufacturing plant of the company are attractively presented in the first few pages of the catalogue. The seven following pages are descriptive of pyrometer applications in the larger industries and contain a full size view showing the upper recording mechanism of the instrument and charts, also a photograph showing the complete accessibility of mechanism. How to select thermo couplers is the subject of the next section of the catalogue, wherein base and rare metal elements and their protection are described and various thermo-couplers and protecting tubes illustrated. The importance of correct interpretation of pyrometer readings, pyrometer maintenance, cold junction errors and how they are eliminated, suppressed zero instruments are the features next taken up. The remaining pages contain specifications and recommended heat treatments for S. A. E. steel, Fahrenheit-Millivolt equivalent charts, a conversion table of Fahrenheit and Centigrade scales and a table of melting points of chemical elements.

Personal Mention

General

C. P. Perot, motive power inspector of the Pennsylvania at Altoona, Pa., has been appointed motive power inspector, office of superintendent of motive power, Southern division.

W. R. Cuttrel, motive power inspector of the Pennsylvania at Altoona, Pa., has been appointed motive power inspector, office of superintendent of motive power, New Jersey division.

R. G. Bennett, superintendent of motive power of the Eastern Ohio division, Central region of the Pennsylvania, has been promoted to general superintendent of motive power of the Southwestern region of the Pennsylvania, with headquarters at St. Louis, Mo., succeeding F. G. Grimshaw. Mr. Bennett was born on March 31, 1882, at Brighton, England, and was graduated from Purdue University in 1908. He entered railway service in January, 1900, as a machinist apprentice on the Pennsylvania, and completed his apprenticeship in 1904. While attending college, Mr. Bennett was employed during summer months as a machinist, draftsman and inspector on the Pennsylvania. In November, 1908, he was appointed motive power inspector. In March, 1912, he was transferred to the maintenance of way department as a rodman; in March, 1913, appointed inspector in the tests department in charge of the locomotive test plant at Altoona, Pa.; in May, 1916, promoted to assistant master mechanic; in February, 1917, promoted to assistant engineer of motive power of the Central division; in July, 1917, appointed master mechanic at Sunbury, Pa., and in May of the following year, transferred to the Pittsburgh division. He was promoted to superintendent of motive power of the Central Pennsylvania division in December, 1919.

R. G. Bennett

O. P. Reese, assistant general superintendent of motive power of the Northwestern region of the Pennsylvania, at Chicago, has been appointed superintendent of motive power of the Eastern Ohio division, Central region, succeeding R. G. Bennett. Mr. Reese was born on May 20, 1876, at Louisville, Ky., and was graduated from Purdue University in 1898. He entered railway service in August, 1898, as an apprentice the Louisville & Nashville, which position he held until September, 1900, when he became a draftsman for the Pennsylvania at Allegheny, Pa. From September, 1900, to September, 1901, he was engaged on special work for that road at Fort Wayne, Ind., and from the latter date to August, 1903, he was a special apprentice. In August, 1903, he became gang foreman at Allegheny, Pa., and held this position until February, 1904. From this time on he held the following positions consecutively: February, 1904, to December, 1904, foreman of tests for the Pennsylvania at the St. Louis World's Fair; December, 1904, to May, 1905, motive power inspector; May, 1905, to May, 1906, general division foreman; June, 1908, to June, 1910, division master mechanic; June, 1910, to September, 1911, assistant engineer of motive power; September, 1911, to May, 1915, master mechanic; May, 1915, to January, 1917, assistant engineer of motive power in the office of the general superintendent of motive power of the same road; January, 1917, to March, 1920, superintendent of motive power of the Central system of the Lines West of Pittsburgh, at Toledo, Ohio; March, 1920, to April, 1921, the same position on the Northern Ohio division. From April, 1921, to February, 1924, Mr. Reese was superintendent of motive power of the Illinois division, and from February, 1924, until his recent promotion, assistant general superintendent of motive power.

O. P. Reese

Master Mechanics and Road Foremen

J. H. Weston, road foreman of engines of the Minnesota division of the Northern Pacific, at Staples, Minn., has been appointed road foreman of engines of the Fargo division, with the same headquarters.

C. W. Adams, whose appointment as master mechanic of the Michigan Central at Jackson, Mich., was announced in the May issue of the *Railway Mechanical Engineer,* was born on March 17, 1885, at St. Thomas, Ont. Mr. Adams received a public and high school education and in September, 1902, entered the employ of the Michigan Central. From 1906 until October, 1920, he served successively as machinist, erecting foreman, roundhouse foreman and general foreman at St. Thomas. He then became superintendent of shops and remained in this position until his appointment as master mechanic as noted above.

Car Department

H. Marsh has been appointed car foreman of the Ashland division of the Chicago & Northwestern, with headquarters at Antigo, Wis.

H. Barrer has been appointed general car foreman of the Galena division of the Chicago & Northwestern, with headquarters at (Wood Street) Chicago.

G. R. Anderson has been appointed district master car builder of the Chicago terminal, Wisconsin, Galena and Southern Illinois divisions of the Chicago & Northwestern, with headquarters at Chicago, succeeding C. J. Nelson, resigned.

J. C. Byrne has been appointed assistant district master car builder of the Chicago terminal, Wisconsin, Galena and Southern Illinois divisions of the Chicago & Northwestern, with headquarters at Chicago, succeeding G. R. Anderson.

Shop and Enginehouse

A. A. Mader has been appointed boiler foreman of the Atchison, Topeka & Santa Fe, with headquarters at Brownwood, Tex.

R. O. Rogers has been appointed night roundhouse foreman of the Atchison, Topeka & Santa Fe, with headquarters at Waynoka, Okla.

M. L. Carlson has been appointed day roundhouse foreman of the Atchison, Topeka & Santa Fe, with headquarters at Waynoka, Okla.

J. Vogel, boiler foreman of the Atchison, Topeka & Santa Fe at Albuquerque, N. M., has been appointed night boiler foreman, with headquarters at Wellington, Kan.

Purchasing and Stores

G. F. Battenfield has been appointed general storekeeper of the St. Louis Southwestern at Tyler, Texas, succeeding F. C. Warren.

F. C. Warren, general storekeeper of the St. Louis Southwestern, with headquarters at Tyler, Texas, has been transferred to Pine Bluff, Ark.

J. W. Taylor, formerly vice-president in charge of purchasing and stores of the Chicago, Milwaukee & St. Paul and, since the receivership, chief purchasing officer, has retired from active service.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Request for change of address should reach the New York office two weeks before the date of the issue with which it is to go into effect. It is difficult and often impossible to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, be sure to send us your old address as well as the new one.

Subscriptions, including the eight daily editions of the Railway Age published in June, in connection with the annual convention of the American Railway Association, Mechanical Division, payable in advance and postage free: United States, Canada and Mexico, $3.00 a year; foreign countries, not including daily editions of the Railway Age, $4.00. When paid through the London office, 34 Victoria Street, S. W. 1, 17s. 0d. Single copy 35 cents or 1.6d.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulation (A. B. C.).

Railway Mechanical Engineer

Vol. 99 | July, 1925 | No. 7

The spray method of cleaning machinery

In many places, spray guns, similar to those used for painting, are now being used to supplant or supplement the work of the engine wiper and for cleaning all kinds of shop machinery. For cleaning electrical machinery, gasoline is sometimes used as the cleaning agent since it will remove the dirt without injury to the insulation. Probably the greatest objection to the use of gasoline is the fire hazard. Where injury to insulation is not a factor, the fire hazard is eliminated or at least greatly reduced by using an emulsion of water and gasoline. Dirt having a tar content will give way rapidly before a water and gasoline spray. For cleaning the running gear of locomotives, a mixture of water, kerosene and soap is used. The practice of cleaning machinery in this way results in the saving of much labor and in cleaning out-of-the-way places effectively. It will probably be used more widely in the near future and there remains the problem of determining the proper cleaning agent for each application. Different kinds of cleaners are needed and the proper one must be selected for each different application.

How about repair facilities?

Of all the subjects which are reported on by the various committees of the Mechanical Division of the American Railway Association, there is none which touches on a question of much greater importance than that on Locomotive Utilization. The last report of the joint committee and the discussion thereof at the June meeting of the Mechanical Division, an abstract of which will be found on another page in this issue, contains information which is well worth careful study. Operating statistics show that the railroads of this country have handled record-breaking traffic without suffering from a serious motive power shortage. This has been brought about to a great extent by a greater utilization of existing power. In this fact and in the aforementioned report lie a real message to the mechanical department officers, particularly those directly responsible for the operation of engine terminals. One of the big factors in the increased utilization of locomotives has been the extension of runs and the successful application of this operating principle depends upon several factors not the least of which is the maintenance problem. Increased locomotive mileage per day and between shoppings transfers a larger part of the burden of maintenance to the enginehouse repair forces, and because of this fact the master mechanic in charge must be fully alive to the added responsibility—of both organization and facilities. It is not a difficult matter for a wide-awake and progressive man to effect a reorganization of forces that will meet changed conditions. But, how about reorganizing facilities? If the reader happens to be in charge of an engine terminal which has already been, or is liable to be, affected by an operating charge which will tax the existing repair facilities to the utmost, may the suggestion be offered that it might be well to go back and read between the lines of the report and the discussion on "Locomotive Utilization." Therein may possibly be found just the point that is needed to clinch the argument as to why he should have some new machine tools or other facilities to replace those that have been handed down to him.

Effecting better brake performance

The Air Brake Association is an organization dealing with a highly specialized piece of railway equipment, concerning which few, except those who devote their entire time to the subject, can be more than casually informed. This has given the association a high measure of influence as well as a high measure of responsibility. It is interesting to note that during recent years there has been a well defined tendency on the part of this organization to take up actively those subjects bearing directly on the maintenance of air brake equipment in condition to perform its functions effectively and economically, and that in the handling of these subjects there is evident a thoroughness and scientific analysis which is worthy of the consideration of every other organization in the mechanical field. One of the first outstanding pieces of work of this kind was the study of the air consumption of locomotive auxiliary devices which brought to light the tremendous importance of establishing a high standard of maintenance for these pieces of apparatus in order to prevent them from robbing the air brake itself of an adequate supply of compressed air. Even a casual study of the proceedings of this year's convention, an account of which will be found elsewhere in this issue, will show that this association is tackling several problems of maintenance in a way which, when the work is done, will not only have established accurate methods of checking and well defined limits of wear, but will also have presented an array of evidence showing the necessity for the adoption of the standards recommended which will make it impossible for the railroads to ignore the recommendations.

A co-ordinator of departments

The outstanding impression left by the convention of the International Railway Fuel Association, a report of which will be found in this issue, is the wide range of subjects covered, on which papers were contributed by officers of several departments, and the wide range of departmental and group interests represented in the large attendance. The impression was strong that these men had come together not because of a narrow interest in the inside problems of

their own departments, but because of a broad interest in railroading and because of their appreciation of the tremendously important part that fuel plays in railroading. The value of this association, like that of many others in which mechanical department officers are interested, is measured only partially by the permanent value of the committee investigations or individual papers presented and discussed but lies also in the inspiration which comes from the group contact. The inspirational value of the International Railway Fuel Association conventions is particularly important because of the co-ordinating effect it produces in emphasizing the common interest of the various departments in producing a good job of railroading. The opportunity for this kind of co-ordination is undoubtedly greater in the case of this association than in the case of any of the other mechanical department organizations, because they are, by their very purpose, compelled to devote attention primarily to the technical problems of the motive power department or some of its branches. Is there not a possibility, however, for these organizations to get something of the inspiration which comes from a broadened viewpoint by devoting at least a small part of the time of the convention to the consideration of a message from a representative of one or more of the other departments? This is already being accomplished to a certain extent through addresses of executives at the various conventions, but it can be carried even farther to the consideration of papers dealing with some of the problems of common interest between the various departments, of which there are plenty from which to choose.

Wheel Committee favors grinding

With perhaps the prime object of bringing to wheel shop foremen, and particularly mechanics, information which will enable them to understand their work more fully and carry it out more intelligently, the Wheel Committee of the Mechanical Division this year submitted a proposed 100-page Manual on wheel shop practice which holds much of promise for a higher standard and decreased cost of this important work. Considerable space in the committee's report was also devoted to the subject of car wheel grinding, the conclusions strongly supporting contentions of the *Railway Mechanical Engineer* in the past in favor of this method of reclaiming car wheels with slid flat spots and thus at a small cost conditioning them for further service. Without encroaching too much on the findings of the committee, published elsewhere in this issue, it may be said that tests under actual shop conditions showed the average time of grinding a pair of cast iron wheels to be 30 min.; flat spots removed, 3¾ in. long; reduction in diameter on each wheel, ⅛ in.; and total cost, $1.19 per pair. This gave a saving per pair based on second-hand values of $5.31 and, based on new values, of $21.01, figures which indicate plainly the possibilities of economy by grinding slid flat car wheels. Moreover, the tests showed that new car wheels sometimes have a lack of rotundity of 1/32 in. or perhaps more and the treads are more or less rough due to chill marks, both of these conditions being readily overcome by grinding. A pair of new car wheels can be ground in 15 min. or less and assure smooth treads, concentric with the journals, on which there is less tendency for the brakes to stick. The importance of grinding from this point of view is indicated by the number of new car wheels on which the brakes stick and develop flat spots after very brief service. The committee's investigations also extended to the grinding of rolled steel wheels, and a comparison of the cost of turning in a lathe as opposed to grinding gave some highly interesting results. The report showed a reduction in diameter of 1/16 in. by grinding, whereas ⅛ in. was the smallest cut which the lathe tool could take and get under the hardened tread surface, making a total reduction in diameter of ¼ in. The resultant saving in service metal of 3/16 in. in favor of the grinding method was shown in the report to be worth $12.18 per pair of wheels. The important point in connection with car wheel grinding is apparently to select only those wheels in good condition except for the flat spots. Satisfactory results can hardly be expected with wheels already shelled, comby, badly thread-worn or flange-worn.

Why remove the stack?

While sometimes overlooked and seemingly forgotten, the plea for larger and better shop and enginehouse facilities to take care of modern power continues to be heard. In a paper read at the April meeting of the Western Railway Club, Chicago, A. G. Pack, chief inspector of the Bureau of Locomotive Inspection, Interstate Commerce Commission, said, "We find large modern motive power being maintained in the same old shops and with the same old tools that were provided years ago for the lighter equipment. Locomotives, shops and facilities should be modernized if the railroads are to keep abreast with the modern times and render the most efficient and economic service." Examples are not hard to find to substantiate Mr. Pack's statement. At one shop of some importance on a mid-west railroad it was observed that the smoke stack had been removed from one of the locomotives without any apparent cause. The stack seemed to be in good condition; there was no question of interference on the part of the stack which projected into the smoke box. The visitor had already noticed the entire absence of overhead crane facilities in this little old shop with its low roof-supporting timbers and this proved to be the cause of the stack removal. The master mechanic said in explanation, "I have to take the stack off in order to get the locomotive high enough to roll the wheels out from under her." This illustration tells its own story. Not only was there needless labor cost in removing and applying the stack, but the locomotive quite possibly was held in the shop longer than would otherwise have been necessary in order to reapply the stack. Moreover, the morale of the shopmen was bound to be adversely affected. What satisfactory argument or incentive could be offered to shopmen to increase their efficiency and productiveness when they saw wasteful practices permitted by the management of which the instance mentioned was simply an example. Small, poorly-equipped, antiquated and often dirty shops unavoidably mean excessive repair costs.

Mr. Pack also commented on the enginehouse situation as follows: "It is not uncommon to find boilers being washed and extensive repairs being made to locomotives and cars in the most inclement weather out of doors because the equipment has outgrown the housing facilities and in many instances where housing facilities have never been provided. In my opinion, making repairs under such conditions is false economy." Mr. Pack had previously commented favorably regarding the mechanical department officers of today, saying that on the whole they are equal if not superior in skill and ability to any ever employed by the railroads. They have not, however, always been given the support and recognition due them by those in authority. Is not one reason for this the fact that they

have allowed themselves to become so engrossed in the manifold and exacting duties of conducting mechanical department work that they have neglected to show the management just how much antiquated shops and worn-out tools are costing the railroads as compared to modern up-to-date equipment? In other words, have railroad mechanical departments obtained their just proportion of the money spent annually for additions and betterments? Have they not allowed some of this money to go to other departments of the railroads where it would save 10 per cent on the investment when perhaps a saving of 20 per cent could have been obtained by investing it in new shop tools and better facilities for maintaining cars and locomotives?

Interpretations of new Interchange Rule No. 44

The recognized weakness of many of the wood underframe cars, due to decay or other old defects combined with the questionable practice of keeping in service freight cars that are in an advanced state of deterioration, has embroiled the railroads in long and bitter disputes as to who is responsible for the failure of such cars under ordinary handling conditions. Under these conditions a car failure is unquestionably the owner's defect, but the Arbitration Committee of the Mechanical Division, when called on to make a final decision in such disputes is often prevented from correctly placing the responsibility for the damage owing to the impossibility of determining the actual circumstances under which the failure occurs. As a result of these conditions the handling line is often held responsible for damage to cars which should have been charged against the owner. Recognizing the fact that the handling line is entitled to a greater measure of protection than is afforded under the present rule, this year's report of the Arbitration Committee contains a new Rule 44, which definitely points out seven different classes of car failures under ordinary handling which require the handling line to furnish a statement, after a thorough investigation, in order definitely to establish the responsibility of the car owner for the repairs. The committee is to be commended for the inclusion of this new rule in its report as it will not only protect the handling line in the case of failures of badly deteriorated cars but will tend to reduce to a minimum the practice of keeping in service freight cars that are liable to failure under ordinary conditions.

The new rule also provides additional protection to car owners in cases where equipment, in good condition, is damaged in service but cannot be attributed to the provisions of Rule 32. The decisions of the Arbitration Committee have proved many times that it has been bound by the provisions of Rule 32 to charge the car owner with damage to cars which evidence undoubtedly indicated were damaged through too rough usage on the handling lines. Under the new rule if a car, in good condition, fails in any of the ways listed it will be a clear indication that the car has been subjected to unfair usage and the handling line should be held responsible regardless of the fact that the car was not derailed, cornered, side swiped or in a collision.

As a whole, the new rule provides protection for the handling line when passing over its road equipment in a decayed condition and also affords protection to the car owner against being held responsible for damage occurring to its equipment which is in good condition. It should do much to eliminate the constant controversy involved in the interpretation of Rule 32.

What Our Readers Think

Floating bushings have given good results

Greenville, Pa.

To the Editor:

In the April issue of the *Railway Mechanical Engineer*, S. J. Stark asks a question concerning floating main rod butt end and main connection side rod bushings. The following is an answer to his question.

With light locomotives having pins and bushings of small diameter and low tractive force, it often has been quite difficult to keep the main connection side rod bushing tight in the rod and in line with the grease hole below the grease cup. When the bushing keeper bolt was applied in the bottom of the rod it might become lost along the road, making it possible for the bushing to work loose and turn in the rod, thus blankig the grease holes and stopping lubrication, with a consequent hot pin and delay. This difficulty was overcome by drilling and tapping the

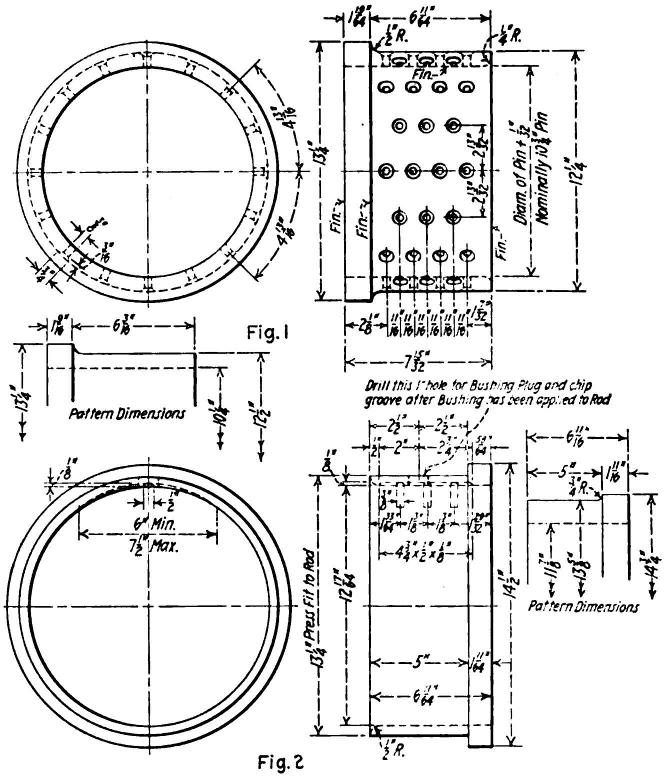

Fig. 1—Main side rod connection floating bushing
Fig. 2—The stationary bushing

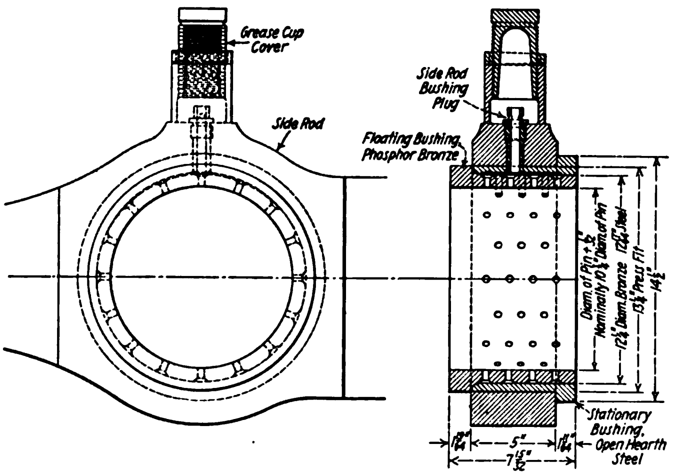
base of the grease cup to take a large diameter hollow bushing keeper. This method, however, produced new difficulties; such as the necessity of drilling out the keeper due to the twisting off of the small head, and on account of the small clearance in the grease cup it also was necessary to have a special wrench to remove the keeper. Even with this method when a large diameter bushing became heated and gripped the pin the leverage of the large diameter pin would shear the keeper at the edge of the hole in the bushing and allow the bushing to turn in the rod, which also shut off lubrication.

The logical conclusion then, since the bushing was

determined to turn, was to allow it to turn, and see that it received correct lubrication. Now, since the brass bushing was to turn in the rod, it would be illogical to allow the resultant wear to occur in the eye of the rod so it became necessary to provide a steel wearing surface by pressing a steel bushing into the rod under heavy pressure and then applying a keeper as a precautionary measure. In equipping existing power with floating bushings it was not considered advisable to increase the diameter of the eye of the rod. This necessitated the designing of the stationary and floating bushing, shown in Figs. 1 and 2, with a combined wall thickness equal to that of the original pressed bushing.

The first class of engines on this road to which experimental bushings were applied was a Santa Fe type having 30-in. by 32-in. cylinders developing a tractive force at 81,600 lb. The main side rod bearing was 10¾-in. inside diameter and the eye of the rod was 13¼-in. in diameter. It was decided to allow the stationary bushing to have ½-in. walls so as to make the wall thickness of the floating bushing of sufficient thickness to fill the remaining space around the pin.

The first experimental bronze floating bushing had two outside circumferential rows with 20 grease holes per row, ¼-in. in diameter, spaced 1⅞-in. on the outside



Drawing showing the arrangement of the main side rod bushing

circumference, staggered and connected inside and outside with zig zag grease grooves. One center circumferential row contained 10¼-in. diameter grease holes. The center circumferential row and zig zag grease grooves were connected on the outside face of the bushing by a machined circumferential groove ½-in. wide and 3/16-in. deep. Operation under service conditions showed that these zig zag grooves provided an easy breaking point for the bushing.

It next was decided to experiment with several parallel circumferential rows of ⅜-in. diameter holes, staggered and countersunk on the outside face of the bushing. Four types of bushings were designed, all having the same wall thickness and the same number of circumferential rows, but having a different number of holes and indicated in the table below.

Style	No. of holes	
1	180	without collar
2	140	with collar
3	72	without collar
4	56	with collar

In order to make a comparative test, several locomotives of the same class were equipped with one type of bushing on the right pin and another type on the left pin. On some engines a similar comparative test, between a new style floating bushing and an old style pressed stationary bushing, was made. After the test in actual service had lasted one year, the following average mileage was shown for the various types of bushings:

Old style pressed bushing	14,000 miles
Zig zag grease grooves with 50 holes	24,902 miles
Style 1	23,565 miles
Style 2	20,041 miles
Style 3	25,158 miles
Style 4	28,640 miles

No further attempt was made to reduce the number of lubricating holes. The floating bushing shown in Figs. 1 and 2 was adopted as standard for this class of locomotives. This bushing had shown an average of 28,640 miles in service, required less machine work, was lubricating properly and was in the best condition at the end of the test. These floating bushings now replace an old style bronze bushing which consisted of a phosphor bronze bearing surface cast inside a gray iron ring.

Material for the old style bushing cost $27.50 while the material for the new combined stationary and floating bushing cost $37.30, an increase of $9.80 or 35 per cent. The machining cost of the new arrangement over the old showed a further increase of 100 per cent for new installations, but this increased cost amounts to only about 25 per cent on bushings applied after the steel bushing is in place. However, to offset these increased first costs we have double the service miles and a greater ease of maintenance in the enginehouse, for with the floating bushing it is not necessary to remove the side rod in order to remove and replace a worn or broken bushing. The saving in enginehouse stall space, labor of replacement, and locomotive service hours more than offsets the additional machining expense.

A clearance between the friction faces of the stationary and floating bushings of 1/64-in. is considered sufficient on lighter power, but on the heavier classes of engines this should be slightly increased, for on these engines the floating bushing with close clearance sometimes heats and binds in the stationary bushing. With an increased clearance the rubbing surfaces remain bright and clear, the bushing rotates easily, and may be removed readily by the enginehouse forces.

From the experience gained from these experiments it was decided to allow just sufficient lubricating holes in future installations, on other classes of power, so that each hole would lubricate approximately 4.35 sq. in. of area on the outside circumference of the floating bushing.

G. Charles Hoey.

Another question about floating bushings

Toledo, Ohio.

To the Editor:

I am writing for information in regards to floating bushings on the back end of main rods. Are they used on switch engines? What method is used to shorten the main rods on this type of locomotive when it is necessary to adjust the length on account of setting up and lining driving box wedges and keying up the front end main rod brasses.

The total piston clearance on most engines is 9/16 in. which leaves 5/16 in. front cylinder head clearance. I find that with solid type back end main rods, on account of both the front and butt end wedges lengthening the rod, it is necessary to watch the clearance closely. This is the reason I would like to know what method is used in keeping the proper clearance with floating bushings.

Sidney H. Kohler,
Shop foreman, Toledo Terminal.

Meeting of A. R. A. Mechanical Division at Chicago

Important reports on locomotive design and construction, design of shops and engine terminals, and car construction

THE 1925 annual meeting of the Mechanical Division, American Railway Association, was held at the Drake Hotel, Chicago, Tuesday, Wednesday and Thursday, June 16, 17 and 18, 1925.

The meetings were called to order at 10 A. M. each morning by J. J. Tatum, general superintendent car department, Baltimore & Ohio, chairman of the Division. The Tuesday session was opened with an invocation by the Rev. Scott R. Hyde, Chicago. This was followed by an address by R. H. Aishton, president of the American Railway Association, and by Chairman Tatum's address, abstracts of which follow:

Chairman Tatum's address

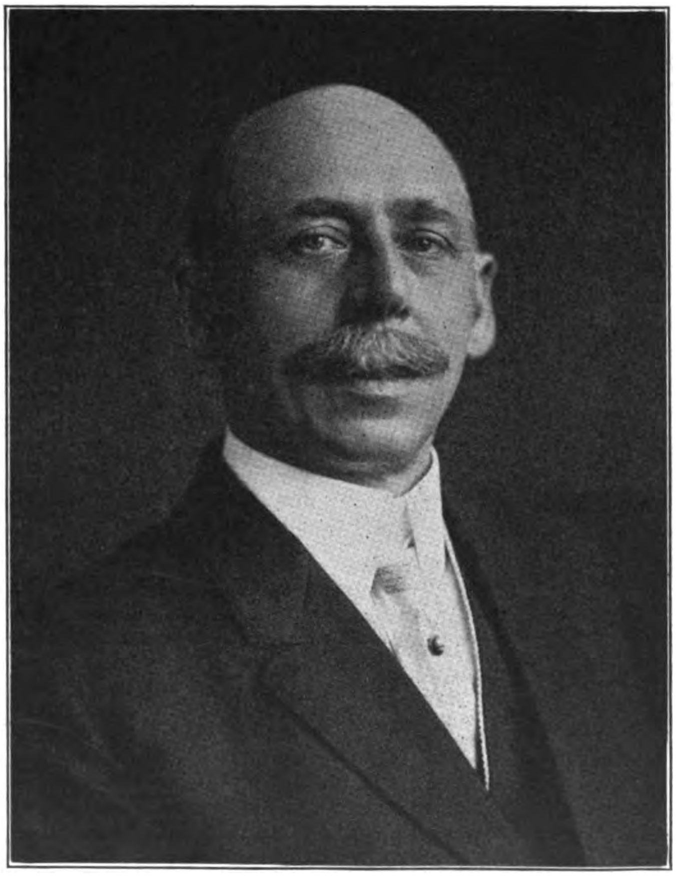
The following is an abstract of Chairman Tatum's address:

The importance of these Mechanical Division conventions cannot be measured and should not be underrated. We should consider the responsibilities resting upon us as members of this great Association.

The proper management of railroad properties affects the investments of over two million stockholders, the greater proportion of them small investors, many of them fellow railroad workers. Railroad securities to the extent of approximately two billion dollars are owned by insurance companies, representing over forty million people. The banks of this nation are holding the savings of its patrons to the extent of seventeen billion dollars, over one billion of which is invested in railroad securities.

To point out further the immensity of our obligations, the statistics of the Labor Board show there are employed in the maintenance of equipment department of all Class I railroads in the United States, as of February 1, 1925, 541,057 employees. In 1924 the expenditures of the maintenance of equipment department of Class I railroads represented $1,270,119,592, or 21.22 per cent of the total operating revenue of $5,986,492,120. In addition to this we are responsible for many of the designs and standards of new locomotive and car equipment on which there is expended yearly many millions of dollars for its purchase.

Our railroads in the past 100 years have been of unparalleled importance in the growth of the United States, when it is considered that during the same period the population of this country has expanded from ten millions to one hundred and ten millions. The wealth of this nation one hundred years ago was less than three billion dollars; today, it is over three hundred billions.



J. J. Tatum
Chairman, Mechanical Division, American Railway Association

Never was there a greater opportunity for the further development of this nation than we have today. Never were the opportunities greater for intelligent, level-headed, hard-working men of high character. Their efforts to manage wisely the accumulated machinery and wealth will not only reflect upon themselves and their dependents, but upon the nation as a whole.

In my opinion the management and economical operation of railroads will depend very materially on the establishment of better understanding and relationship between the public, railroad managements and the workmen. This, I think, can be best brought about by co-operation between the railroad managements and their employees. We must endeavor to understand the employee's side of his relationship with the company as we would have him understand the management's side. As managers we should put ourselves in the workman's place in reasoning out the differences that may exist between us from time to time.

The railroads must be kept in uninterrupted operation. They must provide the service required at all times. This can be accomplished with the peace and good-will of our employees, which is assured when we are willing to co-operate with them and they are willing to co-operate with us. Perhaps the greatest and most effective co-operation can be obtained by having employees become interested in railroad properties to the extent of becoming owners of their stocks. When financially involved we are more conservative in our actions and more interested in the final results than when not so involved. Therefore, if all the employees of railroads were stockholders to a more or less extent there would be a greater assurance of peace and co-operation.

One of the most outstanding reports this year is that of the Committee on Car Construction; the designing of the double-sheathed box car, and the work of the special sub-committee of the Committee on Car Construction in preparing a manual of fundamentals for car design. Another important work was that of the Committee on Wheels. This year they have prepared a manual of wheel shop practices including description of all the different kinds of wheel defects, etc., which they will present.

At the last convention it was thought that we would adopt as recommended practice the all-steel double-sheathed box car. This, however, apparently did not meet with the approval of sufficient members of the association to make this possible. I am pleased to advise, however, notwithstanding the fact that this design of car has not been approved as yet for recommended practice, the Pennsylvania has built 22,000; the Baltimore & Ohio, 2,000; the Read-

ing, 1,000; the Wheeling & Lake Erie, 1,000; the Norfolk & Western, 1,000, and the New York Central, 100—a total of 27,100 cars.

The A. R. A. single-sheathed box car has been approved as recommended practice, and to date I understand the Louisville & Nashville has built 2,500 of these cars; the Southern Pacific, 2,000; and the Missouri Pacific, 2,000—or a total of 6,500 cars. There may be more of which we have no information.

The association approved and has built two double-sheathed wooden box cars, which have been designed during the current year by the Committee on Car Construction.

The most of the work of the association is necessarily borne by a comparatively small number of its members. We need assistance in our annual meetings, conferences and committee work, and I ask that you all contribute a part.

Address of President Aishton

I want to take the opportunity to thank heartily the Mechanical Division, its various chairmen of the General Committee, its present General Committee, the various committees, and the individuals that operate these railroads for what they have done to bring about that result.

Transportation today is adequate. It is reflected in the report I saw in the morning papers from our office at Washington. Take the week before last, which is the last report we have. The railroads of this country loaded and moved 994,874 carloads of freight. Two years ago when we set 1,000,000 cars as the mark, it was the top notch of transportation in this country, and yet week before last, you moved within 5,000 cars of that number at an off season of the year when transportation is not by any means at its maximum, with 300,000 surplus cars and about 7,000 surplus locomotives ready for business when the fall movement comes.

Now, I am no prophet, but I feel confident that no matter what load of transportation is offered to these railways this autumn or in succeeding autumns, there never again is going to be in these United States or in Canada any question as to the ability of the railroads to furnish adequate, prompt, and proper transportation for whatever may be offered. We have made some estimates, and I would not be surprised this fall to see all previous marks surpassed.

There has been a change in the commodities that are being handled. There has also been a change in the distances they have been hauled. The furnishing of adequate transportation has brought about a profound change in the industrial relations of this country. Where it used to be that a man would figure on delays in transportation and stock up for weeks and months in advance, today dealers and shippers are purchasing on the basis of adequate transportation. Adequate transportation has brought about another result, and that is in the amount of capital tied up in goods in transit. The shortening of the time that goods are in the hands of the railroads has brought about very much lower rates on capital and is one of the prime reasons why today money is cheap in this country.

I had a shining example of that just the other day. A man came in to see me, and said, "I don't hand the railroads a bouquet very often, but I think it is due them that I tell you." His company ships ore from Butte, Montana, and Bisbee, Arizona, down on the eastern seaboard. He said, "We recently had to ship a lot of concentrated copper ore down there by rail. We kept an accurate tab on about 500 carloads, and it was on the road only thirteen days." He said, and this is the significant thing, "It has entirely revolutionized our way of doing business. We used to keep big stock piles. Today we are making our shipments according to our daily requirements with the absolute knowledge that that material will be delivered to us as it is needed. The saving we make on interest charges on that copper ore, which is very valuable, alone goes a material way toward paying the freight charges."

There is another side, however, that is not so satisfactory. The work your Division, all the other Divisions of the Association and the individual railroads are doing has been and should continue to be to produce the largest economics that are possible in the operation of these railroads. In other words, keep your eyes and ears open. If you see or hear of a better way of doing a thing, go after it, because one of the great question in the public mind today, and that will be prominent at the national capital in the next year or year and a half, particularly in connection with the investigation into the question of freight rates, their relation to each other, and their adequacy to produce revenue to attract capital, is the economies and efficiencies in the operation of these railroads. You cannot do any greater work than to put in the hands of your representatives who will have to put their case thoroughly before the people and answer that question, the answer as to whether you, as an organization, and your individual railroads are taking advantage of every known thing that is humanly possible to bring about greater economies.

This is the fifty-eighth annual meeting of the Master Car Builders' Association and the Master Mechanics' Association, and their successor, the Mechanical Division of the American Railway Association. In that 58 years your record has been one of continual accomplishment along lines of economy, safety and efficiency. In 1882 there were 56 different kinds of axles in the equipment of the railroads of this country. Today you have one type with six sizes. That of itself is a tremendous accomplishment. In 1882 there were 58 kinds of journal boxes. At the present time you have only one kind with six sizes. There were 26 kinds of couplers. At the present time you have only one. There were 20 different kinds of brake shoes used on freight cars. At the present time there is only one. In 1882 there were 27 different kinds of brake heads. At the present time there is only one kind.

These are some of the things you have accomplished in simplification and standardization that in the end have brought about the ability of these railroads to move freight at a rate per thousand ton miles materially less than that afforded by any transportation by railroad in the world. I am not going into details as to the other things you have done. What I have recited about these various parts of freight cars is an indication of what has been done in every direction.

Take the specifications for materials. Take this standard car that we have had so much discussion about, and about which some of you have felt disappointment because we have not moved faster. I believe that safety in getting the real answer to that matter lies in the fact that you have not moved faster. That is indicated by the standards that you have already prepared and approved in this Division, and which today are very largely governing the building of new freight equipment.

It is my prediction that the next two or three years are going to see a standard car perfected that in its main requirements as to dimensions is going to govern the building of 90 per cent of the equipment in this country. While your accomplishments in the past have been great, there has been no time when such constructive progress has been made in the work of this Division as in the last two or three years.

You are studying a lot of things which some of you think the American Railway Association ought not to consider. But just consider that there are a lot of people, not railroad people, who get these ideas and somebody has to have the answer for them. Who better can find the proper answer for us than you gentlemen who have spent all your lives in the development of this mechanical machine on the railroad?

You made a splendid showing this last year, with $80,000,000 less expense for maintenance of equipment. Quite a part of that is due to the very large amount of new equipment and the vast capital expenditures made by these railroads. I notice that the railroads last year expended $104,682,000 in new shops, improved shops and improved facilities, to reduce the cost of operation.

That brings us to the point that I have already mentioned that, while the service was adequate, there was one side of the question that was not satisfactory. It has been determined by Congress through the Transportation Act that the railroads are entitled to a reasonable return on the capital invested providing the operation is conducted in an efficient and economical manner. The return in no year since the railroads came from Federal control has reached the amount set under the law by the Interstate Commerce Commission as a fair and reasonable return. That rate today is 5¾ per cent. In the year 1923 the railroads were $99,000,000 short of what is a reasonable return on the capital, as indicated by the tentative valuation as prescribed by the Commission, which is not the value as claimed by the railroads. Last year it was $148,000,000 that they were shy, and in the first three months of this year they were still short $21,000,000 of that reasonable return.

Now, of course, the railroads of the country cannot go on spending money, investing capital indefinitely, unless they receive a fair return—such a return as will attract capital, which in turn will provide more economical and more adequate transportation.

So there never was a time when the work of this Division was any more important to the railroads than the present time, for the

next year or two concentrating on those things which will bring about economies and at the same time maintain the efficiency which you have maintained in the last two or three years.

Outside of the matter of economy there is another important thing you want to keep in mind. We heard a great deal for a number of years about the lack of opportunity for management; that governmental activities were taking the place of individual management. I am not at all sure that in some ways possibly we were not a little at fault in not taking the initiative, and that this lack of initiative on our part encouraged action through some arm of the government that felt it must take the initiative. The government does not want to get into the game, but to prevent their getting into the game you gentlemen have got to function. You have been functioning, and today you have got a standing established with the officers of the government such as you never had in your history. And as long as we keep that way there won't be very much question about the government interfering with your management.

Today, as at no other time, when any question arises in regard to something on the railroads one of the first steps taken is to communicate with your chairman. If they can't get him they get me, and I communicate with Mr. Tatum, or whoever may be chairman.

I love the government. Our government is the greatest government in the world, but I love it best when it is not undertaking to manage the railroad business and I am going to try to keep it from doing so if I can.

Report of the General Committee

The report of the General Committee states that the membership of the division at the present time includes 208 railways, representing 399 memberships in the American Railway Association, and in addition thereto, 190 railroads, associate members of the American Railway Association. These railroads, members and associate members of the American Railway Association, have appointed 999 representatives in the Mechanical Division. In addition, there are 1,065 affiliated members and 142 life members.

In addition to a number of routine matters which are formally mentioned in the report, it calls attention to the work of the Director of Research in charge of the investigation of power brakes and power brake systems, through whom arrangements have been made for complete tests of the various brake equipments offered, on the test rack of the association at Purdue University. Attention is also called to the fact that on a recommendation from the Committee on Couplers and Draft Gear an appropriation for $50,000 has been granted to construct a draft gear testing machine upon which tests of draft gears will be made under the auspices of the association with a view to developing a specification for draft gears.

Life members

The report also contained the following list of members who have been made life members during the past year:

Date joined	Name	Title and railroad
1905	Barclay, F. B.	S. M. P., Illinois Central.
1905	Chidley, Jos.	S. M. P., New York Central.
1905	Deeter, D. H.	M. M., Reading Company.
1905	Dickson, J. G.	S. M. P., Spokane, Portland & Seattle.
1905	Dinan, Arthur	Amarillo, Texas.
1905	Downing, I. S.	G. M. C. B., C. C. C. & St. L.
1905	Eberle, Wm. F.	General foreman, Pennsylvania.
1905	Ferguson, L. B.	S. M. P., Alabama & Vicksburg.
1905	McGoff, J. H.	Mech. supt., A. T. & S. F.
1905	Meister, C. L.	Mech, eng., Atlantic Coast Line.
1905	Mullen, D. J.	S. M. P., C. C. C. & St. Louis.
1905	Robider, W. J.	Fibreboard Co., New York City.
1905	Temple, C. H.	Chief of M. P. and R. S., Canadian Pacific.
1905	Wahlen, John	Superintendent,Springfield Electric Railroad.

Obituaries

Following is a list of the members of whose deaths the secretary has been advised, which was also included in the report of the General Committee:

Name	Title and railroad	Died
Banks, O. L.	Superintendnt, Pullman Company	Apr. 23, 1924
Gallagher, F. S.	Eng., Rolling stock, New York Central	Oct. 26, 1924
Garstang, Wm.	Indianapolis, Ind.	Sept. 12, 1924
Haig, M. H.	M. M., A. T. & S. F.	Nov. 10, 1924
Holder, J. A.	Gen. M. B. M., Seaboard Air Line	Apr. 1, 1925
Howard, J.	S. M. P., New York Central	Mar. 24, 1925
Iffla, A. H.	Asst. loco. supt., United Rys. of Havana	Aug. —, 1921
James, Ed. T.	34 W. Broadway, Mauch Chunk, Pa.	Nov. 3, 1923
Jaynes, R. T.	M. M., Lehigh & Hudson River	
Kalbaugh, I. N.	S. M. P., Coal & Coke	Oct. 13, 1920
Kent, F. S.	G. C. I., Pennsylvania	Jan. 19, 1925
Kileen, G. C.	Gen. supt., So. N. Y. Power & Ry. Corp.	Sept. 21, 1921
Lewis, W. H.	Roanoke, Va	June 4, 1924
Linstrom, C. A.	Chief Engr., P. A. & Mck. R.	Sept. 2, 1921
Littell, C. N.	St. Louis, Mo	Sept. 17, 1924
Lord, Alfred W.	S. M. P., Quincy & Torch Lake	Sept. 15, 1920
Lynn, W. K.	Supt., Gulf & Ship Island	
McBride, B.	M. M., Southern	
Meloy, H. C.	Supt., Elec. Appl., New York Central	Oct. 13, 1921
Moir, G. M.	Asst. Supt. Equip., U. S. Railroad Adm'n.	
Monahan, F. J.	D. M. M., Louisville & Nashville	May 20, 1924
Porth, H. W. L.	M. C. B., Swift Refr. Transit Co.	Mar. 2, 1925
Rae, Clark H.	Asst. Supt. Machy., Louisville & Nashville	Dec. 8, 1923
Randolph, L. S.	Baltimore, Md	Mar. 7, 1922
Reid, Chas. H.	Loco. Engr., N. Y. N. H. & H.	1924
Rogers, W. A.	Supt. Shops, Southern Pacific	Mar. 18, 1925
Sheer, J. M.	East St. Louis, Ill	1922
Sinnott, W.	M. M., Baltimore & Ohio	Jan. 1, 1922
Smith, J. L.	S. M. P. & E., Pitts., Shawmut & Northern	Apr. 15, 1924
Smith, W. A.	Chicago, Ill	
Smith, W. G.	Denver, Colo.	Nov. 3, 1921

Westervelt, Jos.	M. C. B., New York Central	
Wightman, D. A.	Warren, R. I.	July 6, 1917
Williams, C. R.	Corning Machine Co.	May 27, 1918
Williams, W. H.	Gen. For., Erie	Mar. 1, 1924
Witt, G.	Lambert Bros. & Wirt	Nov. 6, 1924
Witt, J. G.	M. M., Washington, Idaho & Montana	June, 1923
Woodcock, C. A.	M. M., Caguas Tramway	

The report of the committee was signed by J. J. Tatum (chairman), superintendent car department, B. & O.; J. T. Wallis (vice-chairman), chief motive power, Pennsylvania System; C. F. Giles, superintendent machinery, L. & N.; A. Kearney, superintendent motive power, N. & W.; L. K. Sillcox, general superintendent motive power, C. M. & St. P.; J. Purcell, assistant to vice-president, A. T. & S. F.; C. E. Chambers, superintendent motive power and equipment, Central of New Jersey; C. H. Temple, chief motive power and rolling stock, Canadian Pacific; G. E. Smart, chief car equipment, Canadian National; J. S. Lentz, master car builder, Lehigh Valley; W. J. Tollerton, general superintendent motive power, C. R. I. & P.; J. A. Power, superintendent motive power and machinery, Southern Pacific Lines; O. S. Jackson, superintendent motive power and machinery, Union Pacific; F. H. Hardin, chief engineer motive power and rolling stock, New York Central; W. H. Fetner, chief mechanical officer, Missouri Pacific, and A. R. Ayers, assistant general manager, N. Y. C. & St. L.

Officers elected for the coming year

In electing the officers and members of the General Committee this year, the Rules of Order were suspended and the secretary instructed to cast the ballot of the convention for the candidates proposed by the Nominating Committee. Those elected were as follows:

For Chairman—Term expiring June, 1926:

J. T. Wallis, chief motive power, Pennsylvania System.

For Vice-Chairman—Term expiring June, 1926:

L. K. Sillcox, general superintendent motive power, Chicago, Milwaukee & St. Paul.

For the General Committee—Term expiring June, 1927:

A. R. Ayers, assistant general manager, N. Y. C. & St. L.

W. H. Fetner, chief mechanical officer, Missouri Pacific.

F. H. Hardin, chief engineer, motive power and rolling stock, New York Central.

O. S. Jackson, superintendent motive power and machinery, Union Pacific.

J. S. Lentz, master car builder, Lehigh Valley.

J. A. Power, superintendent motive power and machinery, Southern Pacific Lines in Texas and Louisiana.

W. J. Tollerton, general superintendent motive power, Chicago, Rock Island & Pacific.

To succeed unexpired term of L. K. Sillcox—Term expiring June, 1926:

J. J. Tatum, superintendent car department, Baltimore & Ohio.

The members of the Nominating Committee whose slate was elected are F. W. Brazier (chairman), assistant to general super-

intendent rolling stock, New York Central; H. T. Bentley, general superintendent motive power and machinery, Chicago & North Western; J. J. Hennessey, assistant master car builder, Chicago, Milwaukee & St. Paul; C. E. Chambers, superintendent motive power and equipment, Central of New Jersey; and W. J. Tollerton, general superintendent motive power, Chicago, Rock Island & Pacific.

Report on the design of shops and engine termnials

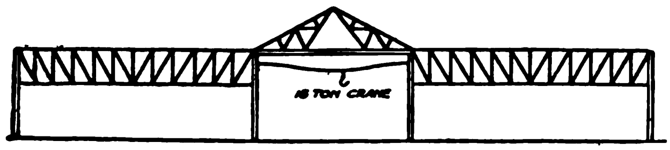
The following report constitutes a study of the design and layout of passenger car repair shops and is presented in response to may recent inquiries to the committee handling this subject for information regarding modern layouts of plants of this nature.

Within the last few years, in all manufacturing plants, much attention has been directed to the routing of the article being manufactured through the various stages and operations necessary to produce the finished article. It has been found that by routing, production is increased and as a result the cost per unit of output is correspondingly decreased. This is the result of:

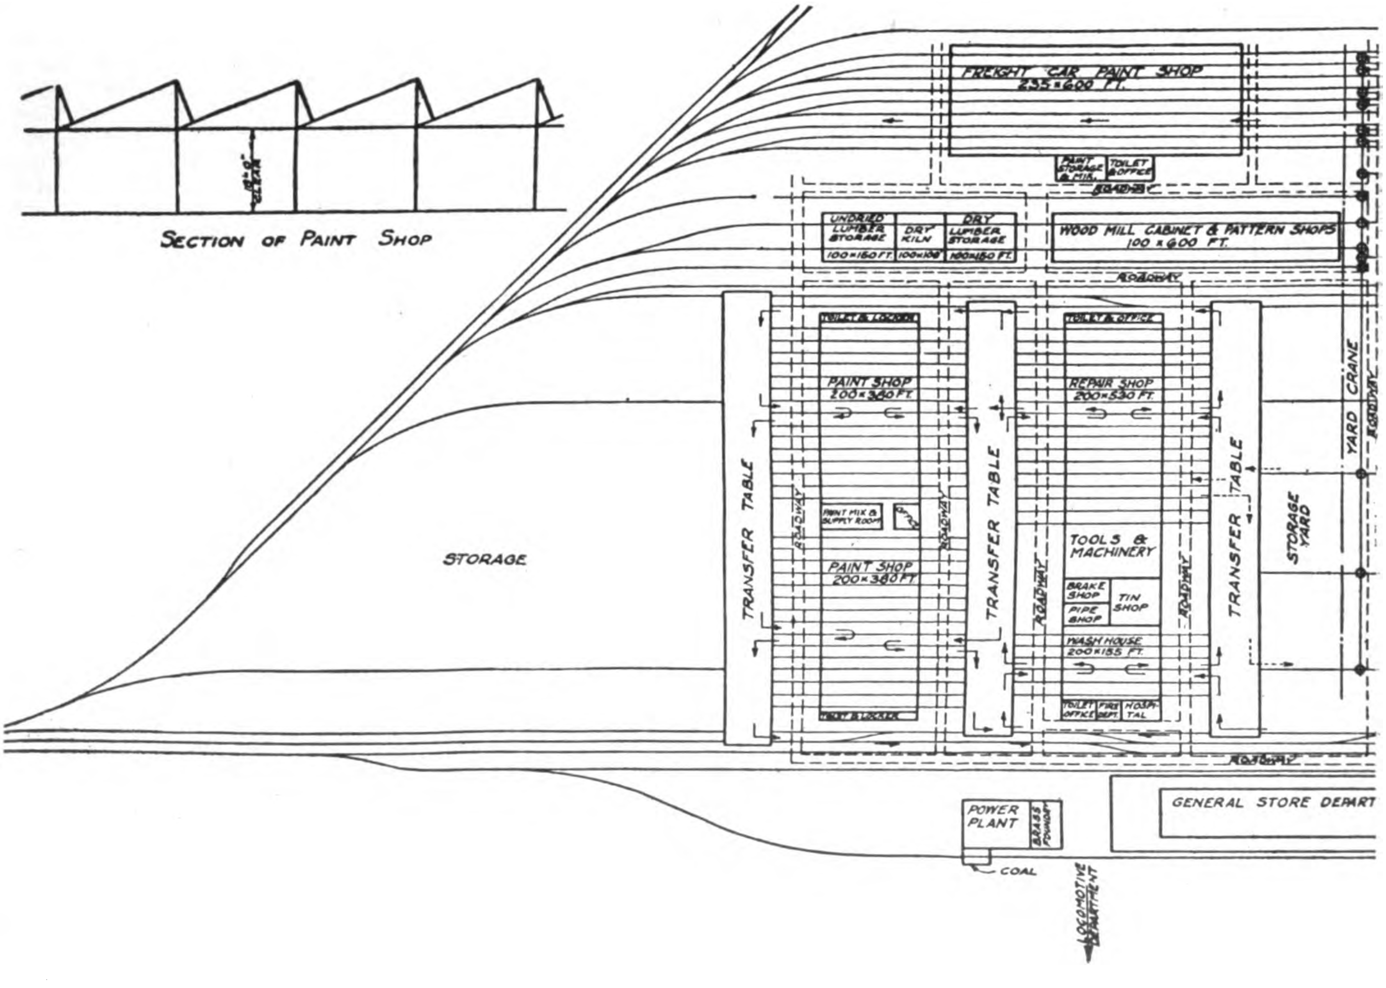
1. Having definite operations for each workman.
2. Reducing waste time of workmen unnecessarily traveling about the shop.
3. Having definite locations for laying down material near the workmen.
4. Moving material by the shortest routes.

The routing systems have perhaps reached their greatest development in the automobile industry. Apparently railway repair shops, in general, have been the last to take up any such system. This is due, perhaps, both to the difficulty of applying such systems to the work of repairing railway equipment, and to the arrangement of most railway plants which are not of recent construction and do not lend themselves easily to routing systems. Even in the more modern shops it does not seem possible to apply a routing system to all classes of repairs. Within recent years, however, the so-called progressive system of freight car repairs has been installed in a number of shops and excellent results have been reported. In canvassing among a number of car shop supervisors it was found that it is almost a unanimous opinion that a modern passenger car repair plant should be designed along the lines of the progressive repair system.

However, in any plan of passenger car shop the progressive system as applied to freight car plants is not equally applicable to passenger car shops, for the reason that it is not convenient to move passenger cars from position to position as is done with freight cars. Nevertheless, it does seem possible to route materials and parts to be repaired from and to passenger cars so as to minimize labor.



SECTION OF REPAIR SHOP



Plan No. 1—A passenger and freight car

In all layouts it is assumed that the cars going into the repair plants will pass in front of or near the electrical shop, plating shop, upholstering shop, and tin shop, and that, when it is most convenient, there will be removed from the cars: the batteries and electrical equipment, plated fixtures, upholstering, water coolers, etc., and these will be sent to the respective shops for repairing. The cars are then moved to the scrub room for interior cleaning. Here the sash, doors, deck screens, etc., are removed and sent to the varnish room for refinishing or, if necessary, to the cabinet shop for repairs. The chairs, tables, and other furniture are handled in the same manner. The cars then proceed to the paint shop or the sand blast building to have the paint removed by burning, or by sand blasting after which they go to the repair shop where all defective parts are repaired.

Upon coming out of the repair shop the cars are passed to the paint shop for refinishing and replacing of sash, doors, furniture, etc., and then move out on a track which is near the track on which they first entered the shop. Here the batteries, upholstering, plated ware, tin ware, etc., are replaced.

Coach repair shop

Coach repair shops are practically all of the transverse track type. The longitudinal track shop can not be used to advantage in repairing passenger train cars. Each transverse track has length sufficient for one or two cars with ample space between them for repairing the ends of the cars.

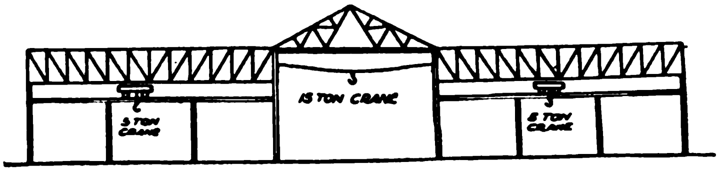
In width the coach repair shop should not be less than the length of the longest coach on the road plus the length of each of the trucks, plus at least a 10-ft. aisle next to the wall and a like aisle between cars in a two car track shop. This will mean a width for a single car track shop of 110 ft. to 150 ft., and for a two car track shop of 220 ft. to 270 ft. The width may be decreased correspondingly if the trucks are not taken into the repair shop, but instead are removed from the cars at a stationary jack on the inbound track. The repair tracks should be spaced at least 24 ft, center to center.

The height from the floor to the bottom chord of the roof trusses should not be less than 22 ft.

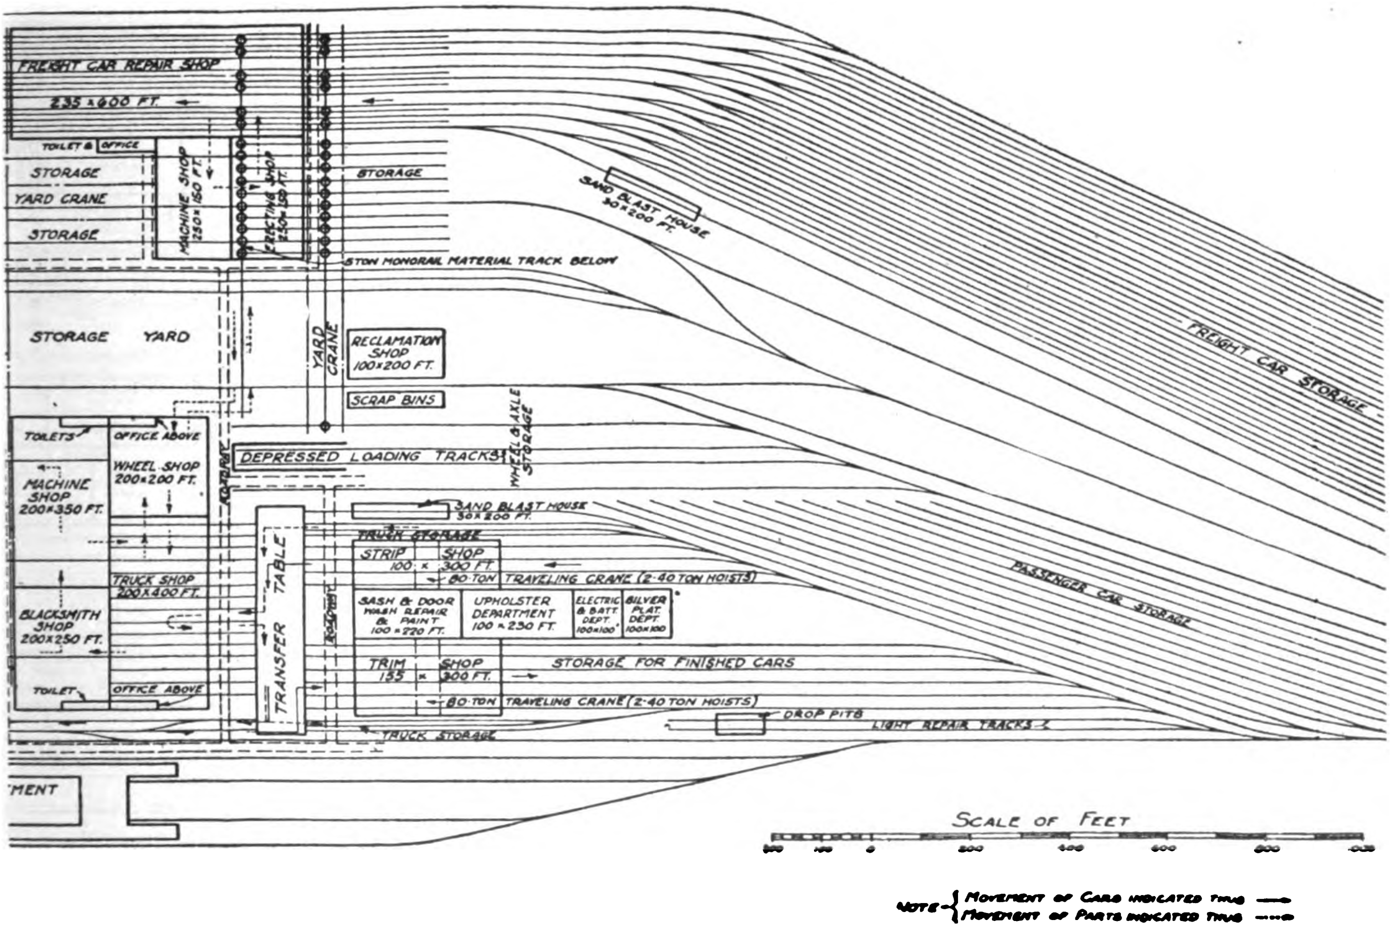
The shop should be piped for water, steam, air, and welding gas, and should be well lighted both by natural light and artificial light. A sufficient number of outlets should be provided for drop cords and for operating electric welding machines and portable motor driven saws, joiners, etc. It is recommended that pipe lines in so far as possible be placed overhead. Underground pipe lines or pipe lines in tunnels are as a rule difficult of access and to repair.

The transfer table should be at least 90 ft. long if the longest modern coaches are handled, and to this should be added the length of the tractor if one is used. The cars are moved either by a cable pulled by a winch on the table or by a tractor. The tractors in use are operated by electric storage batteries or by gasoline motors, and they have either broad treads on the tires for running on platforms and concrete roads or flanged tires for standard gage tracks.

When handling a shop having two car tracks it is recommended



Section of Truck Shop



repair shop proposed for a large railroad

that the transfer table have at least two tracks and if possible three, so that cars can be shifted with a minimum movement of the table. In the case of three tracks two of them are for holding cars from the shop repair tracks and the third is a "run-around" for the tractors.

Truck shop

The truck shop should be located near the repair shop. It is advisable to provide the shop with an overhead traveling crane of at least 15 tons capacity for the shifting of trucks inside of the shop. If the traveling crane is not installed the repair floor should be provided with jib cranes or monorail crane of one and one-half or two tons capacity to assist the workmen in lifting the heavy parts of the trucks.

There should be ample storage space for trucks in the vicinity of the truck shop. In large plants it may be advisable to run the truck shop crane over the truck storage platform. The truck shop should be well lighted and heated and piped for air, gas torches, and electrical welding equipment, and the floor should have a concrete base covered with wood blocks or equivalent.

Wheel shop

The wheel shop should be located adjacent to the truck shop so that mounted wheels can be quickly transferred between the two shops. Also the wheel shop should have about it sufficient storage space for mounted and unmounted wheels and axles, and have depressed tracks for loading and unloading mounted and unmounted wheels.

It is recommended to install traveling crane service over the outside storage platform where the shop is of sufficient size to warrant it. When the crane is provided the depressed tracks are not required. Where one wheel shop is to serve both the freight car and passenger car departments it should be readily accessible to both of these departments.

The pipe shop, air brake shop, machine shop and blacksmith shop should be located close to the coach repair shop. If possible they may be under the same roof as the repair shop and occupy a position similar to that of the machine bay adjacent to the erecting bay in locomotive shops. For securing better light and ventilation it is advisable to locate the blacksmith shop separate from the other buildings, and possibly the machine shop also. These shops should have easy access to a material storage yard provided with racks and bins for pipe, bar iron, steel sheets and steel sections, coal and coke, and other supplies.

Storehouse

The storehouse, or as it is frequently termed the "sub-store" in which are held stocks of bolts, nuts, washers, screws, and also small forgings and castings of all kinds, should be located where men are not required to travel any great distance in reach of it. Even in shops having messenger service where the material men provide the workmen with such materials, much time is saved by having the storehouse close to the repair plant. The storehouse should be provided with an outside material platform and unloading track, and crane service if it can be used to advantage.

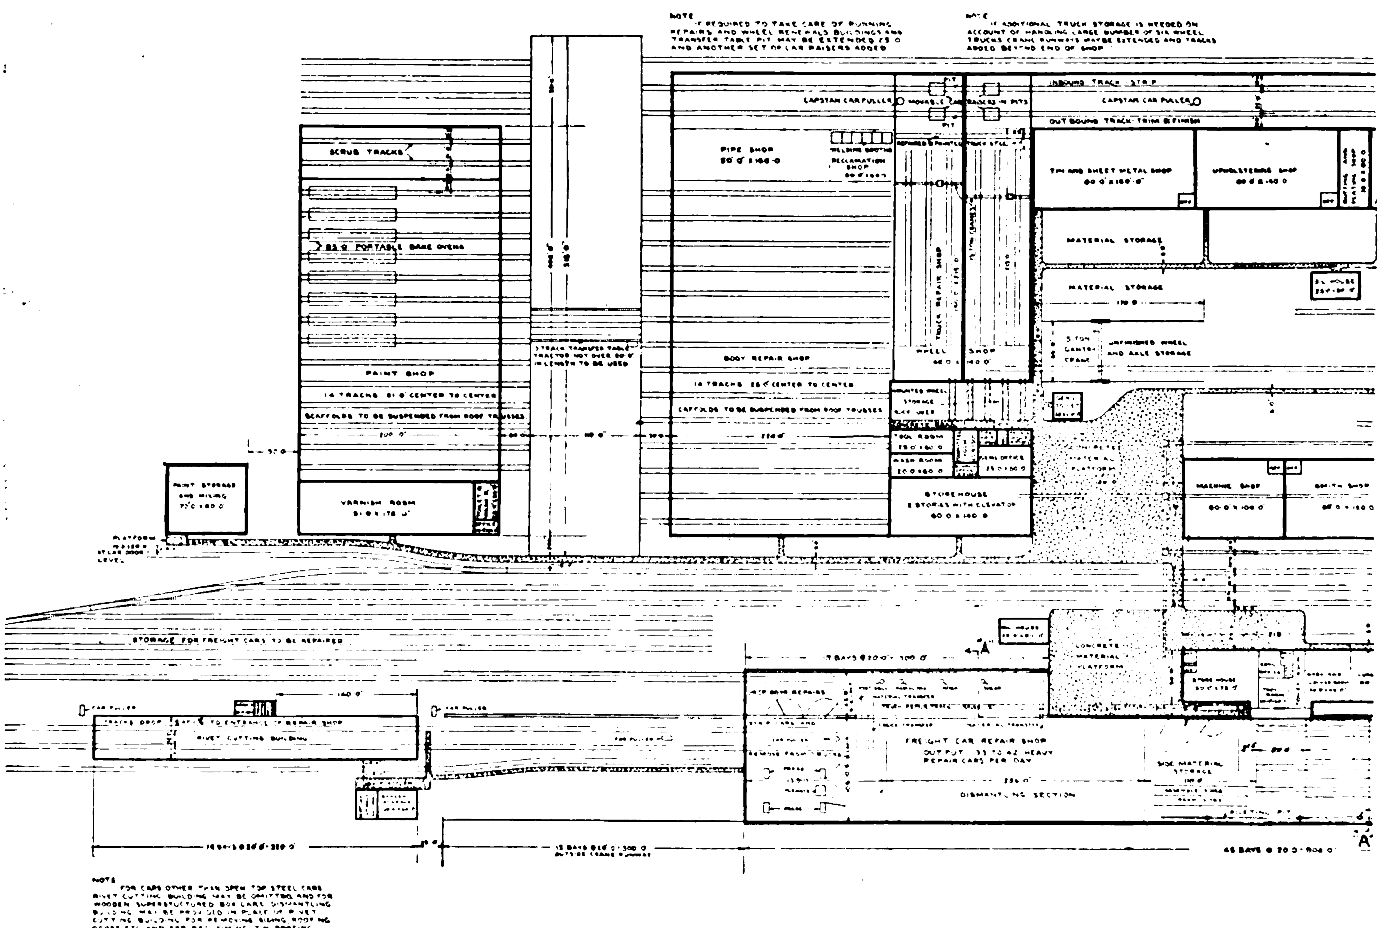
Planing mill

The planing mill is most conveniently situated outside of the main repair shop and in a separate building. The arrangement of machinery and the getting of material to and from the mill is most convenient when so situated, and also the fire hazard about the planing mill is greater than any other part of the repair shop except the paint storage room.

The lumber yard will naturally be located adjacent to the planing mill and the dry kiln interposed between the lumber yard and the planing mill. The lumber moves through the dry kiln, and from machine to machine in the planing mill with the least back motion, and thence to the shop or finished material storage. The planing mill should be steam heated, and have a concrete floor.

Cabinet shop and pattern shop

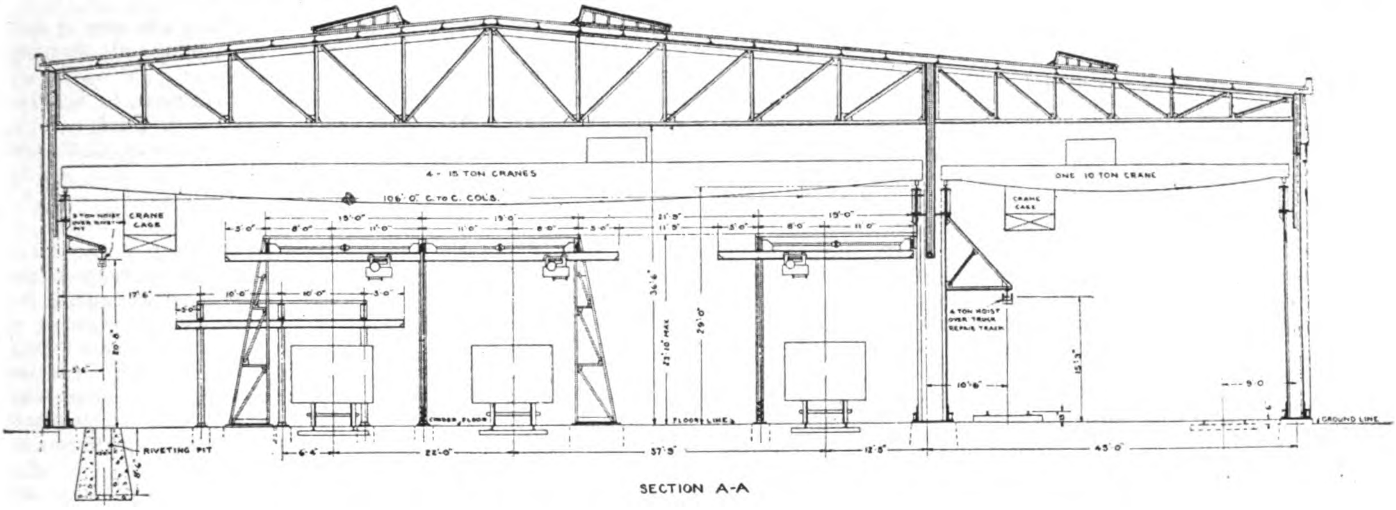
In many existing coach shops the cabinet shop is usually located on the second floor over the planing mill. There seems to be no particular reason for so locating this shop in a modern shop layout. If patterns in any quantity are to be stored a separate fireproof storage vault is advisable.



Plan No. 2—A typical passenger and freight car repair shop

The paint shop, like the repair shop, is preferably of the transverse track type having one or two cars on each track. The width of the building need be governed only by the aisle widths and the length of the cars on their trucks, as it is seldom that a car is off its trucks in a paint shop. Therefore, the building may be from 110 ft. to 125 ft. wide for a one car track shop, and from crete floor to catch the washings from cars. Wood block or other surfacing over the concrete is not required.

Particular attention must be given to the heating of the shop as its efficiency will depend upon the regularity and dependability of the heat. Where paint or varnish is applied with an air spray suitable ventilation should be provided. The shop should be piped



Drawing showing a section through the freight car repair shop—Plan No. 2

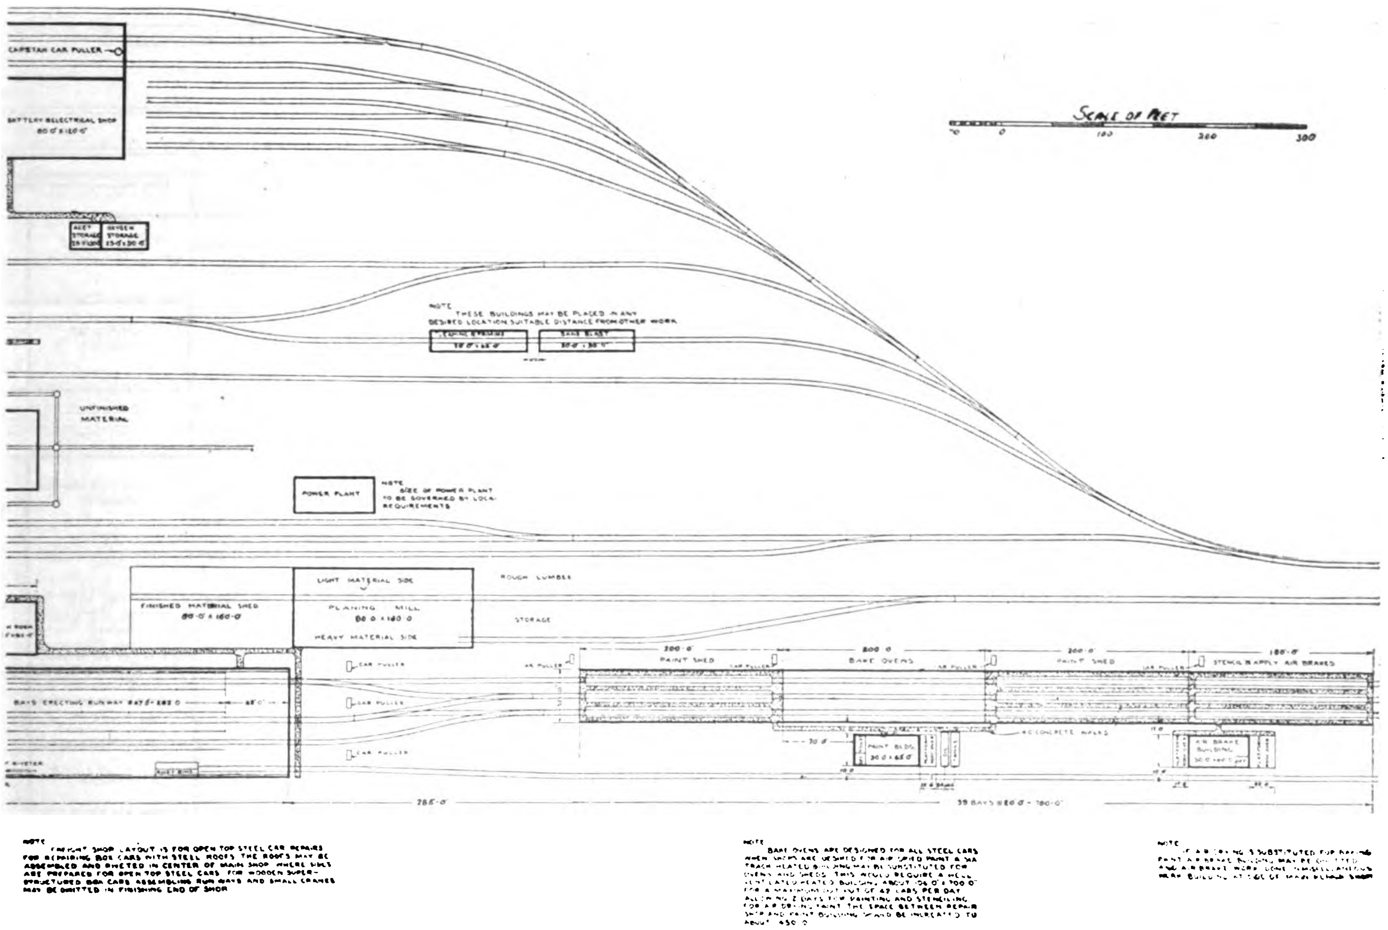
210 ft. to 230 ft. for a two car track shop which allows sufficient aisle space for materials and the workmen.

The tracks should be spaced at least 20 ft. center to center. The number of tracks required for a given output will depend upon the system of painting used. Where the bake oven process is used the painting time is about half that of where air drying is resorted to. The floors should be of concrete and amply provided with drains. In the scrub room troughs should be set in the con-

for water, air, and also gas if the latter is used for burning off paint. Scaffolding suspended from the roof trusses is necessary and the adjustable type is preferable.

Sand blast apparatus

Where paint is removed by the sand blast process the sand blast plant should be located at a distance of at least 250 ft. from the paint shop as the fine dust is easily carried by the wind. It is



—The truck shop is arranged to store the trucks inside the shop building

advisable, and in fact, almost necessary to locate a paint priming room adjacent to the sand blast building as the freshly sand blasted steel rusts almost immediately in damp weather. The priming room should be separated from the sand blast room by two partitions and a space in which air can circulate.

Platforms and roadways

Within recent years material platforms of timbers or old car sills have been superseded by concrete platforms, and such concrete platforms are to be recommended. They do not require renewing as do wooden platforms and also are more easily kept clean and material stocks maintained in order.

With modern shops much of the material is handled by power driven trucks with trailers such as electric storage battery trucks, gasoline tractor trucks, and the like. To operate such trucks efficiently requires concrete roadways and good floors in the shops. Concrete roadways and power driven trucks have practically superseded the former method of handling material by push cars and hand trucks. The concrete roads also serve as fire roads. Therefore, the location of the concrete roadways with reference to the several shop buildings and material platforms is of prime importance.

Fire protection

All railway shop plants comprise a hazardous fire risk and this is especially true of the car department particularly when wooden cars are being repaired. Therefore, ample protection against fire is essential. This protection should include:

1. An adequate source of water that can be supplied at fire pressure.
2. Water mains of sufficient size and properly located with respect to the buildings and furnishing convenient hydrants.
3. Trained fire department of the shop employees supplemented by protection from the city fire department.
4. Concrete fire roads kept clear of obstructions and having easy entrance for city fire department.
5. Sufficient hose reels in buildings, water barrels in lumber yards, and chemical fire extinguishers in paint shop or about especially inflammable materials.
6. Automatic sprinkler systems particularly in planing mill and paint shop.
7. Valves on pipe lines outside of buildings so that gas, water, air, and steam can be shut off from the buildings in case of fire, also switches on outside of buildings for cutting off electrical power and light lines that serve the buildings.

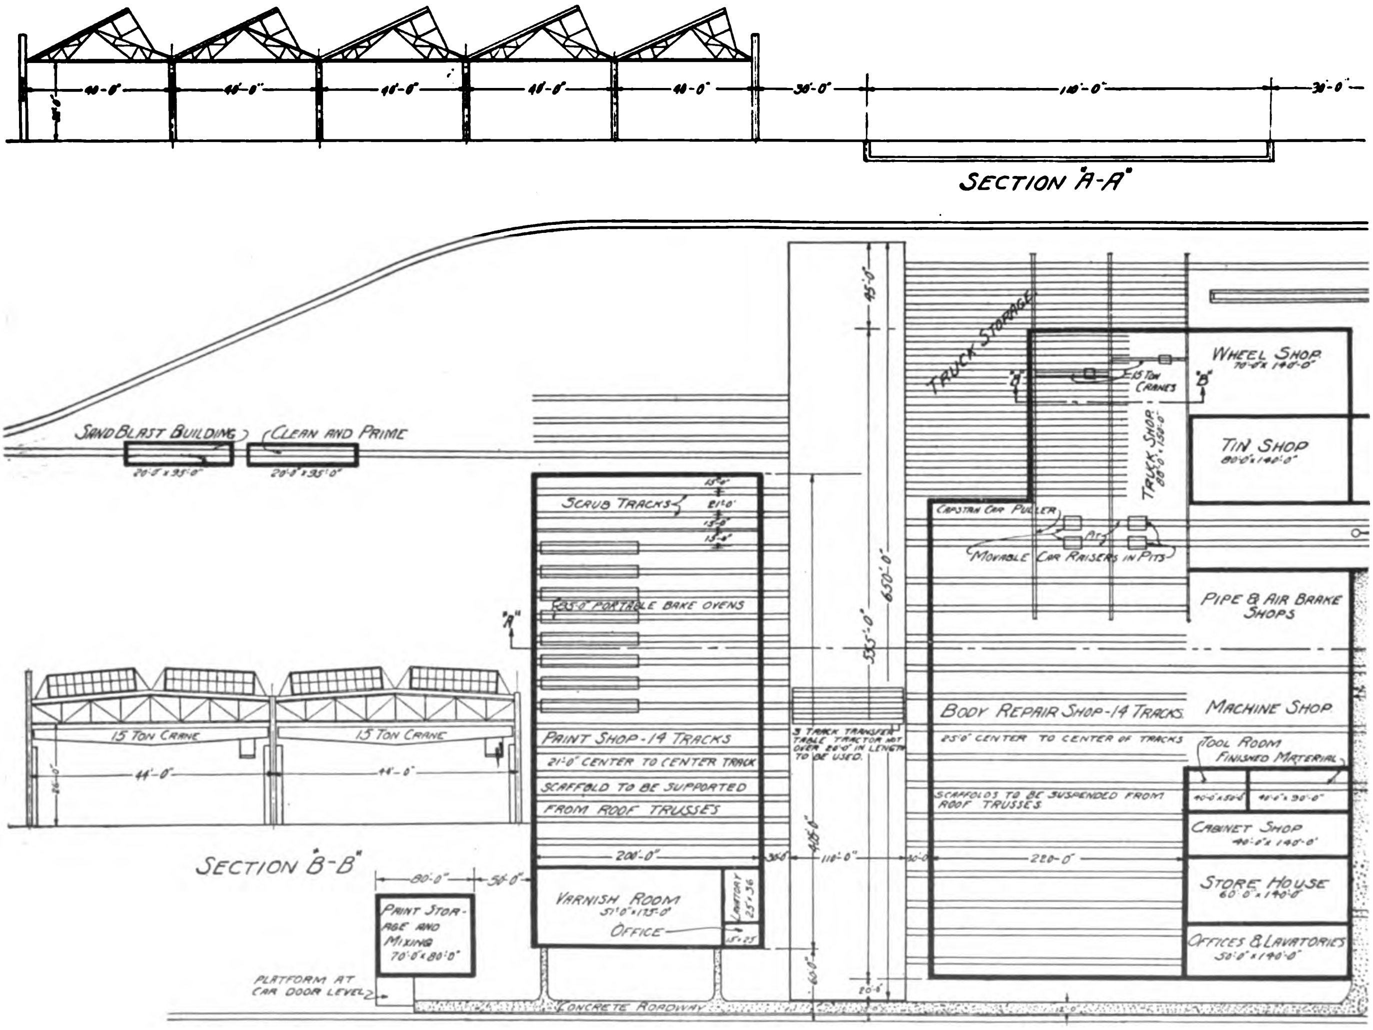
The report is signed by W. A. Callison (chairman), C. I. & L.; A. C. Davis, Penna.; I. S. Downing, C. C. C. & St. L.; B. P. Phelps, A. T. & S. F.; H. Gardner, B. & O.; J. Burns, C. P., and G. S. Edmunds, D. & H.

Discussion of plans

The layout shown in plan No. 1 is adapted only to a very large railroad. It follows the general system of repairs both in the passenger and freight car departments. The plan necessitates the moving of trucks on the transfer table which is not required in plans No. 2 and No. 3. This plan also separates the wheel shop, machine shop and blacksmith shop by some distance from the coach shop. The yard crane, however, connects these shops with the freight car shops. The tin shop is located in the coach repair shop instead of near the upholstering and electric departments as shown in plans Nos. 2, 3 and 4.

In plan No. 2, the machine shop and blacksmith shop are separated from the repair shop building but are connected to it, while the pipe shop is in the repair shop proper. The truck shop is so arranged that practically all the trucks are stored inside the shop buildings.

The truck shop in plan No. 3 is located so that a large portion of the trucks can be stored outside. Also the wheel shop has a



Plan No. 3—A proposed typical passenger car repair shop—

large outside storage platform. Unfortunately, the machine shop and wheel shops are separated by the tin and pipe shops. However, with this location of the pipe and machine shops, easier access to the storage platform from these shops is obtained. The cabinet shop in this plan is located inside of the shop building.

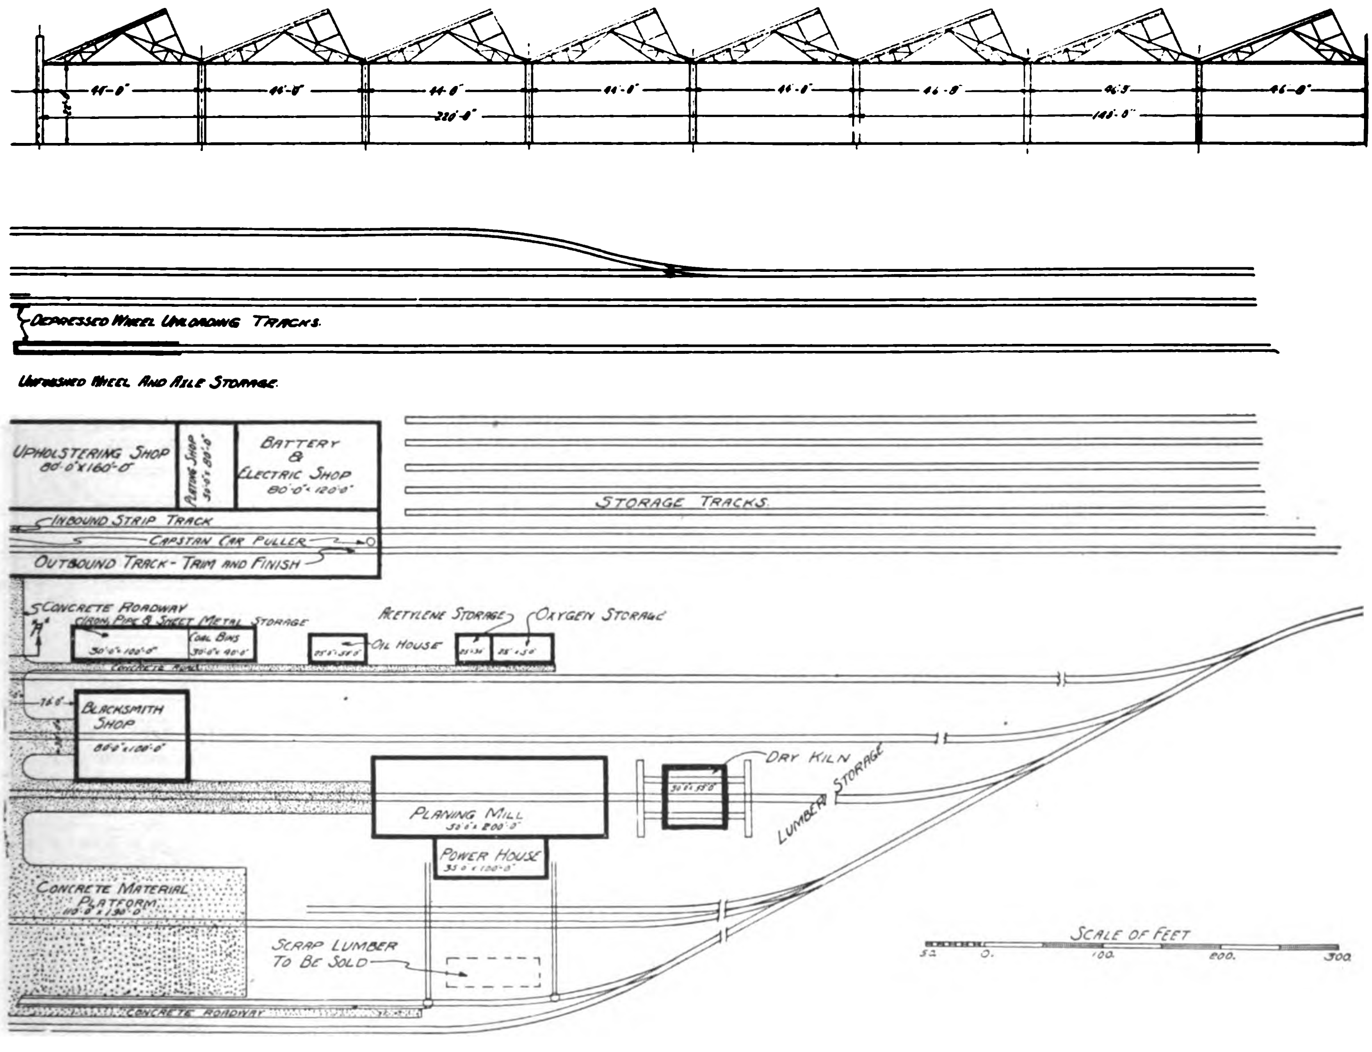
Plan No. 4 is for a smaller plant and locates all of the auxiliary facilities near the inbound and outbound tracks, including the cabinet shop next to the upholstering and varnish rooms. This plan also places the other auxiliary shops such as the pipe shop, blacksmith shop and machine shop, back of the erecting bay of the repair shop. All of these shops have access to the outside material platforms. In this plan the truck shop is supplied with a crane which operates not only over the truck shop, but over the wheel shop as well. The location of the varnish and paint storage of this plan differs from the others submitted.

Discussion

During the discussion the point was brought out that as there was very little wood in a modern passenger car, new passenger car shops should be designed primarily to handle cars of steel construction. With cars of steel body and underframe construction, all metal truck frames and rolled or forged steel wheels, the necessity of locating car repair shops in conjunction with freight car repair shops, in order to use the facilities common to both departments, is not essential. That many mechanical department officers could very well devote more attention to the study of scheduling and routing of work in the shops together with the systematic delivery and handling of material was also brought out. It was generally conceded that the plan of having both the inbound and outbound tracks adjacent, with miscellaneous shops for handling fittings and car equipment in close proximity, is the most practical and economical arrangement. One of the speakers stated that practically all of the railroads in the country would eventually have to provide facilities and equipment for repairing cars of either the gas-engine or gas-electric type and in some cases, even the full motor propelled type. While no radical changes in the plans shown in the report would be required, suitable shop space must be required for repairs to trucks, gas engine, generators and motors with which motor cars are equipped.

The problem of adapting an ideal shop layout such as proposed in the committee's report to all locations, received considerable comment. Conditions vary so much in the several districts of even one railroad that it is impractical to lay down a standard shop plan for all railroads. There are, however, certain fundamentals common to any district that should guide the designer of a shop, among which are a minimum cost of permanent installations; maximum efficiency with minimum idle time of tools and labor, and adequate provisions for safety and sanitation. Any proposed shop plan must justify its cost in actual reduction of repair expense-time to a minimum. A mere convenience is not satisfactory. One of the speakers remarked that it had been found on the road which he represented that the stripping and trimming could be performed in the building and on the tracks assigned to washing and painting, respectively. Two movements of the car were thus eliminated in shopping and the need for a special building is avoided. The trimmings, when stripped, can be loaded on special trucks and hauled in trains to the shop where they are handled. They can be collected in a reverse manner and delivered to the car whenever required.

The method of handling truck repairs received considerable discussion. It seemed to be the general sentiment that the best method of handling truck repairs was to remove the trucks from under the car and place the car body on horses and then move the trucks to the truck shop. It was considered that this procedure permitted a greater working space under the car body and kept the trucks out of the way until they were needed. However,



The cabinet shop is located inside the shop building

a number of the members spoke in favor of keeping the trucks under the cars until they were ready to be repaired.

A motion to accept the report and to continue the committee for the purpose of developing recommendations for freight car shop layout was carried.

The conservation of fuel

By F. H. Hammill

Executive vice-president, C. R. I. & P.

The following is an abstract of an address by F. H. Hammill, executive vice-president, C. R. I. & P. on the subject of fuel conservation.

The public is getting pretty critical about how we operate railroads. I have heard President Aishton of this Association say that we are going to be called upon to show whether or not we operate the railroads efficiently. And one of the big problems is what you are doing in locomotive performance; are you doing it cheaply or not.

I drew up some figures that I think are rather gratifying. It shows some things that have been accomplished. I find that on the Class 1 railroads in freight and passenger service in 1924 as compared with 1920 there was an increase of 4.4 per cent in gross ton miles, or an increase of 40 billion ton miles.

In doing that there was a decrease of 9,000,000 net tons of coal consumed, or 10 per cent. There was a decrease of $132,000,000, or 35 per cent. There was a decrease from 197 lb. of coal per 1,000 gross ton miles in 1920 to 149 lb. in 1924, or a decrease of 24.4 per cent.

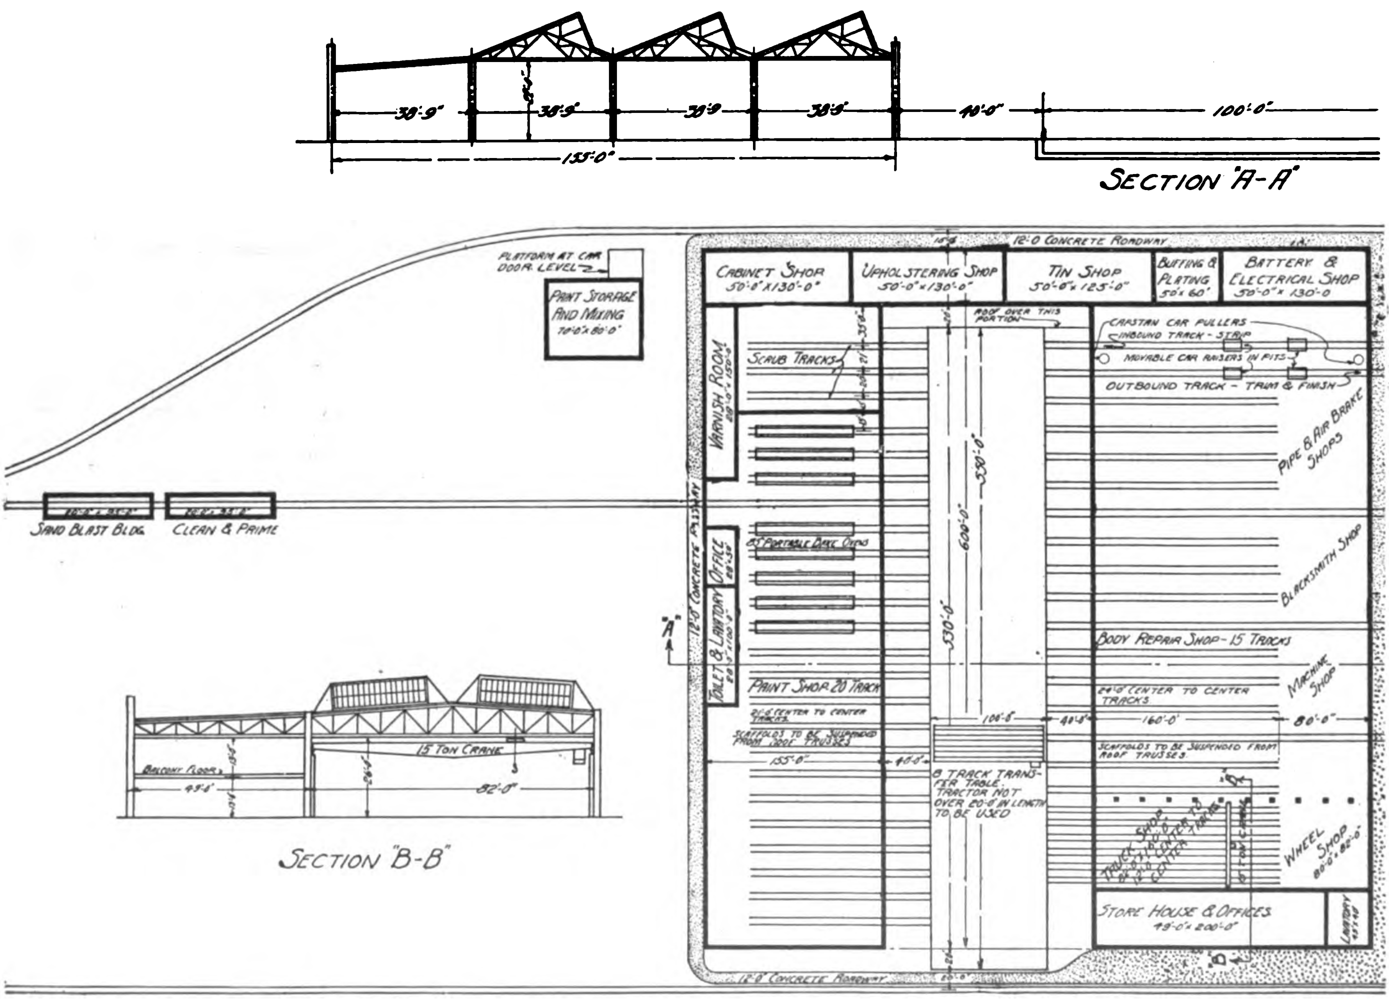
In passenger service there was an increase of 1.4 per cent in passenger car miles with a decrease of coal consumed of 8.6 per cent; a decrease of 9.6 per cent in pounds of coal per passenger car mile.

Taking the two services together we find that in the five-year period there was a total decrease of 9.6 per cent in amount of coal consumed, or 11,900,000 tons. There was a decrease in cost of coal of $180,000,000 or 34.8 per cent. That speaks fine for the mechanical men. The operating man is responsible for the coal. I know at one time it was quite the vogue to make the mechanical man absolutely responsible for the consumption of coal. I take a different position from that. I think the operating man should go with the mechanical man to the limit on the responsibility for that performance.

In the work of the joint committee of the American Railway Association and the International Railway Fuel Association on coal conservation we have been giving quite a little study recently to whether we had gone as far as we ought to as a joint proposition. We are going to win or lose as a transportation machine, not as individual railroads, but on whether we delivered the goods as transportation men. We all know what we have done so far as individual railroads in looking after this coal conservation. The question in the minds of the committee is, shouldn't we do something as a joint proposition. One of the things that I want to call your attention to is this: There were some very fine papers prepared on the question of fuel economy in book form. We find through the committee on coal conservation that they were not distributed as much as we on the committee feel would be of value to the railroads. I would like to call your attention to that so you may look into it.

The next thing is, should we adopt some method of unified testing. We make tests on our various railroads. There is a question in the minds of the committee if it is not necessary for us to go beyond that, not only to defend ourselves in connection with rates and in connection with our transportation as a whole but also to help us to bring about the results we ourselves consider necessary.

Our committee has made a recommendation to the A. R. A. as to whether we should not avail ourselves of some of these



Plan No. 4—A proposed typical passenger

colleges that have good testing plants so we can get some universal information. We all know what the superheat has done for the locomotive. We have other appliances that we know about. If we had some plan of that kind, couldn't we get more detailed information?

We ought to get our problems before the people just the same as other groups get their problems before them. If I have any criticism to offer at all about the transportation business it is that we have been a little too prone to lay back and not talk our subject. The time has come when we should talk.

At the Illinois State University, at Purdue and I think also at Iowa State College are good testing plants. If we could get together as an Association and work out some plan of utilizing these plants we would not only develop the information for the railroads as a whole but we would come in contact with the boy getting his education. He goes back home and gets into some little argument there about the railroads, how they are conducted and whether they are properly conducted. The boy says, "I think they are because right at the present time at the Illinois University where I am going we have locomotives there testing them out. Why? So as to reduce coal costs and enable the railroads to operate as cheaply as they can."

Report on locomotive utilization

The Joint Committee on Utilization of Locomotives presents herewith a report of progress. The committee has collected and analyzed considerable data on this subject, and has conducted some field surveys of operating conditions and performance. From this study, it is evident that the railroads generally are fully alive to the importance of this subject, and very creditable performance is being made.

The performance indicated by these surveys and studies of the Committee is as a result of the careful application of the following principles:

1—Locomotives are given such maintenance attention at monthly periods, preferably at certificate time, to condition the locomotive to run to the next monthly repair time with the minimum of light running repairs. This plan reduces materially the average mechanical time held at terminals, is a great factor in reducing engine failures, and provides a definite plan of running maintenance for keeping the locomotive in better condition.

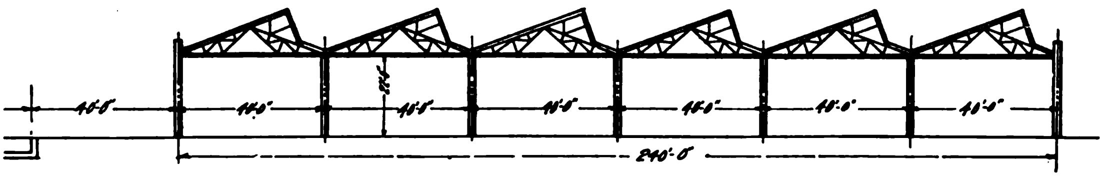
2—Detailed analysis of operating conditions on each division is made to determine the practicability and economy of increasing the miles per locomotive despatchment. The ability and capacity of modern locomoitves to make long sustained runs successfully has been definitely established.

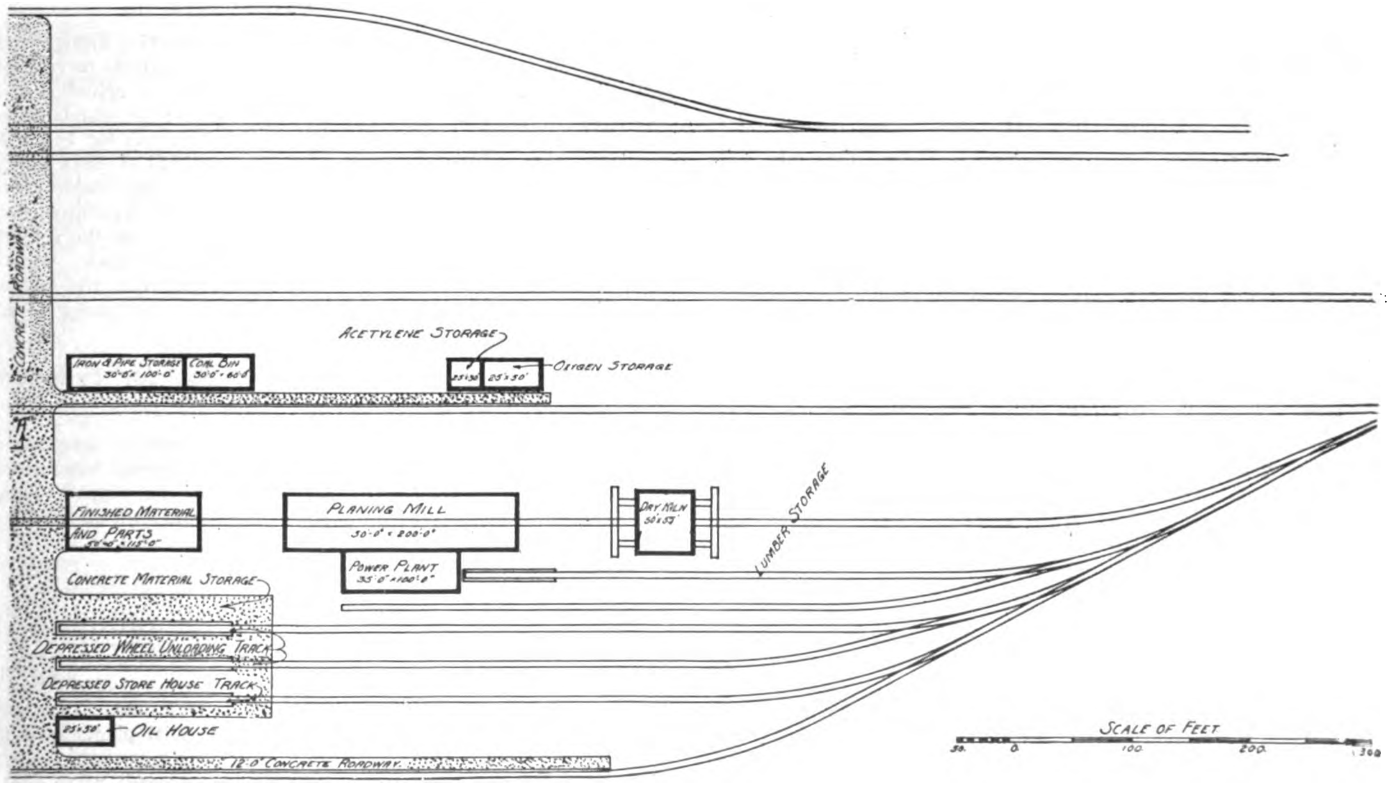
3—Methods pursued in placing locomotives in and withdrawing locomotives from reserve, are very carefully worked out and adhered to. Consideration is given to placing this on miles per day basis, and placing the responsibility therefor on the division people. Specified miles per day are established for all classes of service for each division. Authority and responsibility is definitely placed on the division trainmaster and master mechanic for the number of locomotives in service to maintain this mileage.

4—Time for initial and final terminal delay at each point is established. Consideration is given to the location of route between engine house and yard, and interference encountered in this movement. Consideration is also given to relatively low cost capital investment improvements that will expedite this movement. Definite responsibility is also placed for the maintenance or improvement of this established figure with a local transportation officer.

5—The maintenance of specific locomotives is assigned to specific engine houses, and the utilization of inadequately equipped terminal facilities for turn-around purposes only.

6—Methods followed at yard offices in computing train loading and supervision held responsible therefor is also carefully in-





car shop—This plan is for a small plant

vestigated and studied. This matter is also followed up by the operating officers.

7—Consideration is also being given to re-location of or additional fuel and water facilities with reference to stops fouling the yard or cross-over switches, the location of these facilities with reference to the main tracks and the development of plans predicated on extended runs for correct location of facilities.

8—Statistics relating to performance of locomotives are carefully maintained and studied as relating to average miles per locomotive per month, gross ton miles per train mile, gross ton miles per train hour and related transportation statistics.

9—Thorough consideration is given to the reduction of freight train road delays with reference to despatching, spacing, overtime, relatively low capital investment improvements, and the method of supervising outlying points where congestion often exists and points where fuel and water are obtained.

10—Prior classification is obtained as far as possible and restriction of pick-ups and set-offs reduced to a minimum number of trains.

Where the greatest utilization of locomotives is obtained, and the best performance found, the above principles are being applied by operating officers on each division. Also, the operating and mechanical officers of the entire railroad are displaying the greatest interest in the subject. The committee invites suggestions and information as to the other practices which have been found effective by the members.

Upon request, executive officers of railroads will be supplied with confidential copy of reports of field surveys made by the committee.

[Attached to the report were tabulations of condensed operating statistics of a selected number of roads and of all Class I roads.—Editor.]

The report is signed by the following:

Representing Operating Division: T. B. Hamilton, vice-president, Pennsylvania; J. T. Gillick, general manager, Chicago, Milwaukee & St. Paul, and A. E. Ruffer, transportation manager, Erie.

Representing Mechanical Division: W. H. Flynn, superintendent motive power, New York Central; W. H. Fetner, chief mechanical officer, Missouri Pacific, and O. S. Jackson, superintendent motive power and machinery, Union Pacific.

Discussion

O. S. Jackson (V. P.) briefly described the system of making running repairs periodically on the Union Pacific. Locomotives, he said, are now in better condition, as reflected by a notable reduction in the number of engine failures. The figures per 100,000 locomotive-miles being as follows:

Year 1920	3.57 failures
Year 1921	2.10 failures
Year 1922	3.29 failures
Year 1923	1.54 failures
Year 1924	1.11 failures

Since the adoption of this plan maintenance costs have also been reduced. While it was not considered that the plan itself was entirely responsible, it was felt that it had an influence on the reduction of costs of running repairs. It was also a factor in increasing the mileage between general overhaulings. The plan used is as follows: When a locomotive is due for the regular monthly inspection required by Federal law, it is held long enough to be given such attention as is necessary to put in condition to perform satisfactory service until the next monthly Federal inspection is due. This work is handled along definite lines and under certain prescribed rules for each locomotive held, depending on its condition, length of time out of shop, class of service, etc. With the ordinary trip inspections and ordinary light running repairs during the intervening time, locomotives can be, and are, put in condition to operate successfully between monthly inspections.

The Union Pacific, Mr. Jackson said, has been able to reduce its active locomotive assignment by about 25 per cent as a result of increasing the miles per locomotive despatched, and as a result of this experience has extended this method of operation until all main line power, both freight and passenger, are assigned to long runs. The only exceptions are the local and branch trains. Passenger locomotives are now assigned to runs of from 483 miles to 640 miles in length and freight locomotives from 225 miles to 337 miles in length. From an economical standpoint this method of operation has met the fullest expectations, he said; the saving in locomotive investment and in intermediate terminal improvements and maintenance and the reduction in the amount of fuel used at intermediate terminals, represents a large saving in operating costs. In addition to the saving in fuel used on the locomotives at intermediate terminals, there has also been a considerable reduction in the amount of coal used in the power plants of these terminals. As an instance he cited the saving of 540 tons per month at the Rawlins, Wyo., power plant, by running freight locomotives through from Green River, Wyo., to Laramie, with practically no increase in the amount used at these two terminals.

J. M. Nicholson (A. T. & S. F.) stated that the investigations of the committee show a mileage of from 11,000 to 12,000 per month for passenger locomotives and of 5,000 to 6,000 per month for freight locomotives on portions of certain railroads, and that such mileages are resulting where locomotives are in productive service approximately 50 per cent of the time. He called attention to the fact that locomotives are being turned at terminals on some railroads operating long runs in 12 hours, of which approximately 8 hours is required for mechanical attention and 4 hours for transportation delay awaiting trains, and suggested that if this represents the minimum amount of time necessary, a greater locomotive utilization will result if a reduction of terminal time to this figure can be effected. He called attention to the fact that conditions existing on certain divisions lend themselves best to turn-around runs and in others to the regular assignment of locomotives to crews, while in some cases the best results may be obtained by pooling the locomotives on a single district, with turntable attention at one terminal and all maintenance taken care of at the other. He said that the best utilization, however, is being made by extending runs over more than one operating division and that this operation is recommended by the committee wherever practicable.

The importance of having favorable fuel, water and weather conditions in order to operate extended locomotive runs successfully was referred to in the discussion, as was also the fact that the arrangement or proper coaling facilities on the main line must be taken into consideration.

J. Purcell (A. T. & S. F.) said that in running locomotives on runs from 349 to 600 miles during the past year or two it had been found that in addition to the fuel saved in firing up there were less firebox, flue and staybolt failures than before the long runs were adopted.

Report on locomotive design and construction

During the past year the Committee on Locomotive Design and Construction gave consideration to the comparative merits of hydrostatic and force feed lubrication for locomotive cylinders and steam chests, and the best methods of application; the standardization of taps and dies used by railroads, and standards for bolt and screw threads; definition of an engine failure; rail stresses under locomotives; standardization of water columns; removable hand rail columns; and special designs of engines. The committee had no authority to conduct tests to obtain original data on the subject of rail stresses under locomotives and no report was made. However, investigations are in progress at the present time, the results of some of which have already been published. Following is an abstract of the reports on several of these subjects.

Hydrostatic and force-feed lubrication for cylinders and steam chests

Inquiries sent to the manufacturers of locomotive force feed lubricators requesting a statement as to the number of lubricators in service or on order as of March 1, 1925, developed that there are now in service, or on order, force feed lubricators of the various types, as follows:

Nathan Manufacturing Co.		386
United States Metallic Packing Co.	McCord	694
Formerly Locomotive Lubricator Co.	Schlacks	1308
Edna Brass Manufacturing Co.		36
Madison-Kipp Corporation (Information not available)		
		2,424

These lubricators are distributed over quite a wide range, including 76 railroads and 13 logging or commercial plants owning locomotives.

The expressions received from the various railroads using force feed lubricators indicate that this method of lubrication is exciting

considerable interest, and as a general proposition is establishing a favorable impression. A total of seven roads co-operated with the committee in the pursuit of this subject. These reports embraced the comparative performance of hydrostatic versus force feed lubrication on a total of 22 locomotives. With the exception of four, these locomotives were equipped with hydrostatic oil delivery to one side and force feed delivery to the opposite side. The summarized results referred to, and from which some conception may be obtained of the influence of the method of oil delivery upon packing ring service, rate of wear and oil consumption, are shown in the table.

In preparing the table showing the relative results obtained from the two systems of lubrication, the record as obtained in passenger and freight locomotive service has been separated according to the class of service, following which a combination of the results, including both passenger and freight service, is also shown. There were 14 passenger locomotives under observation, during which time 38 valve rings in the hydrostatically lubricated positions, and 45 in the force feed lubricated positions were removed on account of being worn, broken or down. From these valve rings an average service of 13,471 miles was obtained with hydrostatic lubrication, and 11,749 miles with force feed lubrication. From these same locomotives there was a total of 72 and 104 cylinder packing rings removed from the hydrostatic and force feed positions respectively. The average mileage per cylinder ring was 7,600 for the hydrostatic, and 6,550 for the force feed.

A representative number of rings removed were measured for radial wear at five equally spaced points around the ring from the ends, and from the mileage performance record of these rings the average rate of wear per 10,000 miles has been determined, which, for the hydrostatic lubrication, was .027 in.; force feed lubrication, .029 in., the rate of wear being practically equal. Comparing the mileage made per pint of oil there is a marked difference favorable to force feed lubrication since an average of 50.6 miles per pint of oil was secured as against 30.5 miles for the hydrostatic. Attention is called, however, to the wide range in the oil consumption figures as indicated by the maximum and minimum results. With hydrostatic lubrication the maximum and minimum mileage per pint was 49.1 to 15.9 miles respectively, while with the force feed lubricator the range was from 101.8 to 21.4 miles respectively.

In freight service, there was a total of eight locomotives under observation. The performance of the valve packing rings was not sufficiently complete to enter into the comparison. Considering the cylinder packing rings there was a total of 22 removed from the hydrostatic and 25 from the force feed positions. The average mileage made by these packing rings was 1,954 and 2,600 for the hydrostatic and force feed lubricators respectively. Comparing the performance on the basis of the average radial ring wear per 10,000 miles, the record shows a rate of .239 in. and .197 in. for hydrostatic and force feed lubrication respectively. The mileage per pint of valve oil in freight service was favorable to the hydrostatic lubrication, 32 miles having been realized as against 26.7 for force feed lubrication. It is necessary to call attention to these individual values established in the comparison of the two methods of lubrication in order that a comprehensive idea of the results of this study as a whole may be obtained.

In passenger service a difference of 13.8 per cent in cylinder packing ring service in favor of hydrostatic lubrication is shown, while in freight service a difference of 33 per cent favorable to force feed lubrication is recorded. On the basis of radial cylinder packing ring wear per 10,000 miles service, the results from the two systems of lubrication are practically equal in passenger service, while in freight service a difference of 17.6 per cent is shown favorable to force feed lubrication. Considering the mileage obtained per pint of valve oil, a difference of 65.9 per cent favorable to force feed lubrication in passenger service is shown, while in freight service the difference is 16.6 per cent, favorable to hydrostatic lubrication.

In the consideration of the performance record to which reference has just been made, no striking difference between the two systems of lubrication from any basis of comparison carries through both freight and passenger service. In passenger service a better valve and cylinder packing ring performance was obtained from hydrostatic lubrication, while a better mileage performance per pint of valve oil was secured from force feed system. In freight service a better cylinder packing ring performance was obtained from the force feed system, while a better mileage performance per pint of valve oil was obtained from the hydrostatic system. There is a slight difference favorable to force feed lubrication.

Hydrostatic versus mechanical lubrication of locomotive valves and cylinders

			Rings removed (worn, broken or down)						Cylinder packing ring wear					Causes of cylinder ring removals				Engine miles per pt. of valve oil

The committee, in reporting on the standardization of taps and dies and also on the accepted standards for bolt and screw threads, suggested that in view of the disposition of the railroads and the association to adopt screw threads which do not conform to the Sellers or U. S. Standard tables, particularly for special purposes, such as boiler work, pipe work, injector couplings, etc., the statement on page L-27 of the Manual, to the effect that "The Sellers or Franklin Institute system of screw threads is the standard of the Association" should be qualified so as to avoid conflict between this statement and other standards and recommended practices which have been, or may be, adopted.

The committee feels that in the case of thin castle nuts, whose use, insofar as locomotives are concerned, is confined almost exclusively to crank pins, knuckle pins, crosshead pins, piston rods, etc., the form and number of threads per inch in the nuts should be governed by the threading of the parts to which they are applied.

The committee also feels that the form of threads to be used for lubricator fittings should be definitely specified.

Attention has been called by the committee on Locomotive and Car Lighting to the fact that the association has no standards for bolts or machine screws smaller than ¼ in. diameter, which is the smallest size included in the Sellers or U. S. Standard tables. This committee has therefore undertaken the work of ascertaining the present practices of the various roads with regard to sizes and threading of machine screws.

Status of standard threads

Information has been received from 20 roads. Fifteen report having no standards of their own, but are either following, or rec-

ommend following, the A. S. M. E. standards. Three have adopted as standard a certain number of sizes which are included in the A. S. M. E. standards, but have not adopted the entire A. S. M. E. table. Two roads report having standards of their own which do not agree with the sizes and threading found in the A. S. M. E. tables. In view of the predominance of the A. S. M. E. sizes, it seems proper that the sizes and threads that are adopted for machine screws should be selected from the A. S. M. E. tables.

As the Operating Division has not yet appointed a committee to confer with this committee on engine failures a report of progress only is made. The following memorandum is submitted for discussion and with a view of obtaining the views of the members for the benefit of the committee for future consideration.

1—All delays waiting at initial terminal caused by some defective part of locomotive.

2—All delays on account of the locomotive breaking down, running hot, not steaming well, or having to reduce tonnage, on

(g) Locomotive steaming poorly or flues leaking on any run where a locomotive has been delayed (for other cause than defects of locomotive) on side tracks or on the road an unreasonable length of time, say fifteen hours or more, per 100 miles.

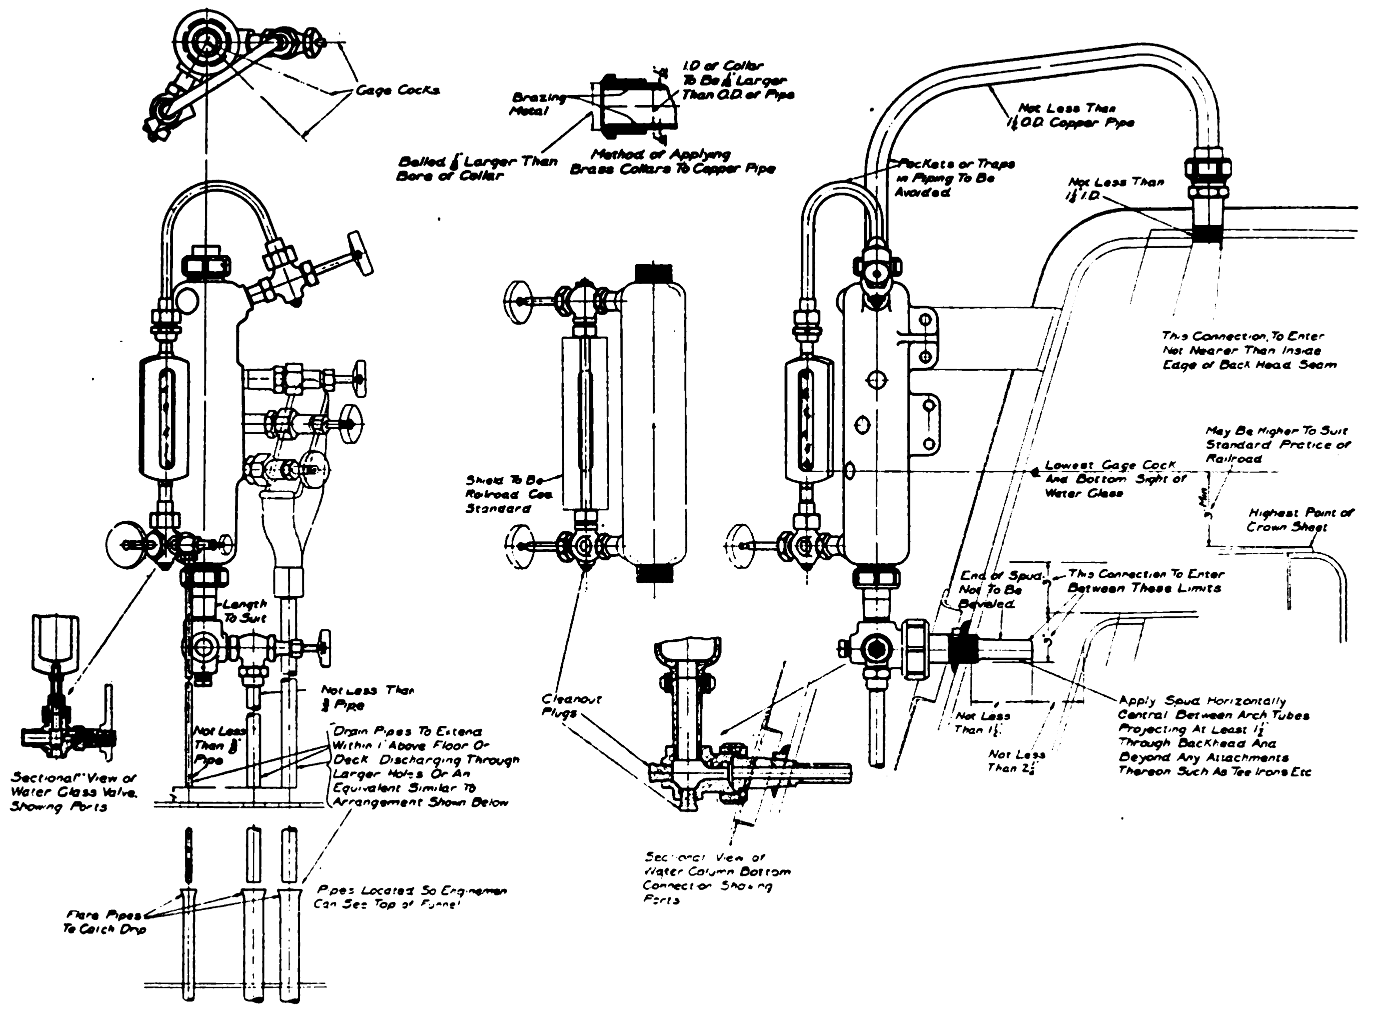
(h) Reasonable delay in cleaning fires and ash pans on the road.

(i) Failure of locomotives coming from outside points to shops for repairs, whether running light or hauling a train.

(j) Delays due to insufficient time having been allowed in which to make needed repairs or to get the locomotive ready for the time the train is ordered to leave, when the operating department was so advised at the time locomotive was ordered.

(k) Broken draft rigging on locomotives and tenders, caused by a bursting hose of the train breaking-in-two.

(l) Delays to fast scheduled trains when weather conditions are such that it is impossible to make time; providing the locomotive is working and steaming well.



Drawing showing the application of the water column to the back head

account of defective locomotive, making a delay at terminal, meeting point, junction connection or delaying other traffic.

The following will not be considered as locomotive failures:

(a) When locomotives lose time and afterwards regain it without delay to connections or other traffic.

(b) When a passenger or scheduled freight train is delayed from other causes, and a defective locomotive makes up more time than it loses on its own account.

(c) Delays to passenger trains when such delays are less than five minutes at terminals or junction points.

(d) Delays to scheduled freight trains when they are less than twenty minutes late at terminals or junction points.

(e) Delay when a locomotive is given tonnage in excess of rating and stalls on a grade, providing the locomotive is working and steaming well.

(f) Delays on extra freight trains if the run is made in less hours than the number of miles divided by ten.

(m) Delay due to the locomotive being out of fuel or water, caused by being held between fuel or water stations an unreasonable length of time.

Report on standardization of water columns

In the report on the standardization of water columns the committee made a total of 28 recommendations for future installations which are as follows:

1. All water columns and water glasses must stand vertically.

2. The water column should not be less than three inches inside diameter and of sufficient length to accommodate the length of water glass required for the operating conditions and to have a clear opening for the top connection of not less than 1½ in. inside diameter and be connected to the boiler with not less than 1½ in. outside diameter copper pipe, tapped into the boiler on the top center or in a location not farther to the side than nine inches and

not nearer than nine inches to the inside edge of the back head seam.

3. The top spud connection standard in the boiler to be not less than 1¼ in. inside diameter.

4. The bottom end of the column, to provide for vertical range in location, should be supported and connected to the boiler with a heavy cross connection and spud with clear straightway bored port ¾ in. diameter, with the cleaning plugs located opposite the horizontal and vertical ports. The spud should be of forged steel or bronze of ample strength to carry the weight of the column and attachments.

5. The bottom water column vertical connection to be not less than 1¼ in. inside diameter, preferably larger.

6. The back head of the sloping type may be reinforced with open hearth steel bevel washers, welded in place to provide horizontal application to the bottom spud.

7. The bottom spud must not be located in a radius or knuckle of the back head flange or immediately above the arch tube opening.

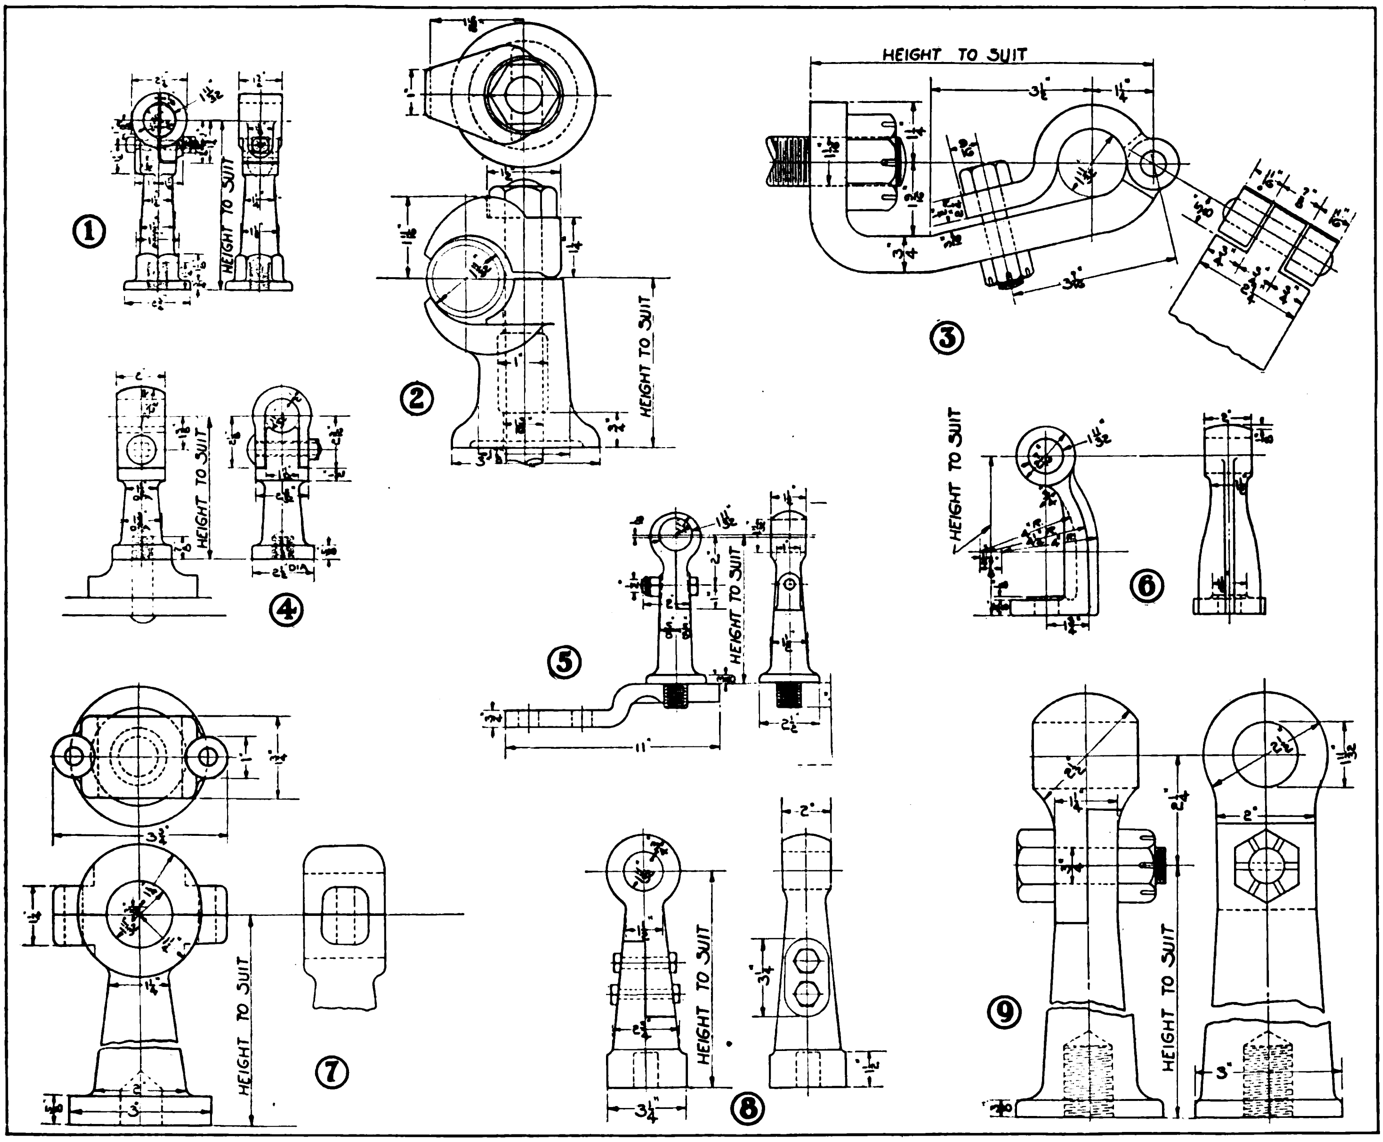
8. The inner end of the bottom spud must extend not less than 1½ inches through the back head and beyond any attachments thereon, such as the tee, angle iron, boiler braces, etc., to avoid location within a water eddy or pocket where water may dam up.

9. The inner end of the spud must not extend to or be less than 2¼ inches from the firebox door sheet and be located in a vertical range between 3 inches below and 3 inches above the back end of the firebox crown sheet.

10. The water column, vertical location, must be at such a height that the lowest gage cock attached therein, and the lowest visible reading of the water gage shall be not less than 3 inches above the highest part of the crown sheet and may be located higher, to suit the standard practice of any railroad.

11. The bottom connection of the water column must be equipped with not less than ¾ in. drain pipe and valve, preferably one-inch, which can be easily opened and closed by hand, so that the water column and connection may be frequently blown out. The drain pipes should be well braced and extend separately to within one inch of the cab floor or deck, and discharge the waste steam or water through a hole, slightly larger than the diameter of the pipe, or an equivalent arrangement whereby the leakage discharged through these pipes may be observed above the deck.

12. Water columns should be located well toward the center of the back head of the boiler to afford protection and to avoid violent fluctuation of the water while rounding curves. Extension handles to be applied to gage cocks when necessary, so as to bring them within easy reach of the engineman.



The nine designs of hand rail columns submitted by the Committee on Locomotive Design and Construction

13. Gage cocks must be not less than ¼ in. inside diameter.

14. The top end of the water column should be securely braced to the back head with a brace sufficiently heavy to carry the weight of the column and overcome vibration.

15. The water column should be equipped with one water glass and three gage cocks.

16. The lowest reading of the water glass to be on line with the center of lowest gage cock.

17. The water glass of the Klinger or other Reflex type should

have stems not less than ⅝ in. outside diameter and ⅜ in. inside diameter.

18. Tubular glass when used to be ⅝ in. outside diameter.

19. The top and bottom pipe connection to the water column and water glass must be applied without gaskets.

20. The water glass steam pipe connection not less than ½ in. outside diameter, preferably ⅝ in. outside diameter.

21. The water glass, Klinger or Reflex type, top and bottom valve connection bore ⅜ in. diameter, "and bottom connection provided with cleaning plug located opposite the vertical port and the side outlet for the blow off pipe connection."

22. The water glass, tubular type, top and bottom valve connection bore not less than ¼ in., preferably 5/16 in., "and bottom connection provided with cleaning plug located opposite the vertical port and the side outlet for the blow off pipe connection."

23. The water glass vision not less than six inches, preferably eight inches, depending on operating conditions.

24. The tubular type water glass when used must be equipped with a removable safety shield which will prevent glass from flying in case of breakage.

25. The water glass must be so located and maintained as to be quickly observable by the enginemen.

26. The water glass must be equipped with a bottom blowout valve and pipe not less than ⅜ in. diameter.

27. Steam pipes to be applied without sharp bends or pockets and provided with ball joint connections and belled at least ⅛ in. in diameter at the end in the bracing collar.

28. Application is shown by drawing.

Removable hand rail columns

The committee submitted nine different designs of hand rail columns which provided for the ready removal of the hand rail. Local conditions, the position of the hand rails and the uncertainty as to a general demand for such a design suggested the presentation of several designs which embodied this special feature. The report recommended that individual railroads considering the use of a removable hand rail should be in position to select from the several designs submitted, one that would probably meet their requirements.

Locomotive development

There has been a remarkable reawakening of interest in increasing the efficiency of the modern locomotive, with two main objects in view; first, fuel economy, and second, increased utility of the machine.

While this movement is attributed by some to the demands of the general public, it is the committee's opinion that it has been brought about by the necessity of improving the locomotive to meet changing conditions of traffic and to keep pace with the great improvements in roadway, terminals and general industrial developments. Coincident with this, great interest has been aroused in fuel saving devices due to the increase in fuel costs, forcing engineers, particularly in foreign countries, to investigate the possibilities of the turbine and internal combustion locomotive. These developments and the building of heavy electrical locomotives have served as a means of advertising the shortcomings of the steam locomotive, unjustly, thereby preventing to a great extent, a realization of what is being done to increase the efficiency of the orthodox types of steam locomotives.

The body of the report contains a summary of the progress being made in steam locomotive development along conservative lines; it listed the major improvements to ordinary designs of locomotives, cited examples by which increased boiler capacity had been obtained, gave an account of the advantages obtained by the use of positive limited cut-off and the development of the three-cylinder locomotive. The report also reviewed the economies effected by changes in operating practices and their effect on steam locomotive design, the condensing turbine locomotive, and the high pressure water tube boiler type locomotive, of which the "Horatio Allen" of the Delaware & Hudson is a typical example. Comments were made on the McClellan water tube fire box locomotive on the New York, New Haven & Hartford and the possibilities of high pressure locomotives.

Part two of the report was devoted to a summary of developments on the internal combustion locomotive. It stated briefly the characteristics of the heavy oil engines and the various problems connected with the application of Diesel power to locomotive service. The report confined its summary to the developments in electrical and geared transmission. It concluded with a discussion of the advantages and disadvantages of the oil-electric locomotive.

The report was signed by H. T. Bentley (chairman), C. & N. W.; H. A. Hoke (vice-chairman), Penna.; A. Kearney, N. & W.; George McCormick, S. P.; W. L. Bean, N. Y., N. H. & H.; C. B. Young, C. B. & Q.; M. F. Cox, L. & N.; W. I. Cantley, Lehigh Valley; C. E. Brooks, C. N.; G. H. Emerson, B. & O.; H. H. Lanning, A. T. & S. F.; A. H. Fetters, U. P.; M. C. M. Hatch, M.-K.-T.; S. Zwight, N. P., and R. M. Brown, N. Y. C.

Discussion

The greater part of the discussion of the report of the committee on locomotive design and construction was devoted to the McClellon firebox locomotive. V. L. Jones, New York, New Haven & Hartford, outlined briefly the history of the development of this type of firebox. The New Haven purchased two locomotives equipped with McClellon fireboxes in 1916, he said. These two locomotives went into the shop in 1920 at which time the back head and the bottom of the combustion chamber tubes were rebuilt and the locomotives replaced into service. Since then they have been in continuous operation, including the period during the strike, with a total expenditure of about $300 for maintenance.

Mr. Jones said that the difficulties encountered in the back heads of the original locomotives were overcome in the new design by providing separate braces and taking away from the tubes any other duty except to carry water and steam, and so placing them that they were able to expand and contract without interfering with the firebox strength in any way. In order to avoid bringing in too many new features on one locomotive, the new features were confined to the firebox construction. The designers did, however, he said, take advantage of the water tube construction and raised the pressure up to 250 lb. That necessitated stiffening up the rods and also required some modification of the valve gear so that the valve motion in full gear cuts off at 70 per cent of the stroke instead of near 90 per cent. No provision was made on this locomotive for auxiliary starting ports, and up to the present time, Mr. Jones said no difficulty has developed from the locomotive being slippery in getting out of holes with a heavy train.

Replying to a question as to the time required to wash a boiler equipped with a McClellon firebox, Mr. Jones stated that this work could be done a little quicker than on boilers of the ordinary type. Scale does not accumulate as rapidly on boilers of ordinary construction, he said, possibly due to the rapid circulation which has some scouring action.

The question of high boiler pressure also received considerable discussion and in this connection, the new locomotive, "Horatio Allen" of the D. & H., received considerable attention. G. S. Edmonds, Delaware & Hudson, stated that the total amount expended for maintenance on the boiler of this locomotive did not exceed $50, and that it required a little longer time to wash this boiler than that of the ordinary type. Until recently it was the practice to blow out the flues at each end of the run, he said. An experiment was made, however, in which the locomotive was run for one month without blowing out the flues. They were then washed out. This practice was carried out for a month or two and then instructions were issued not to blow or wash out the flues until the indications showed that it was necessary and these flues have been run three months without blowing. It has been found that this locomotive carries water equally well, if not better, than the normal locomotive. The highest normal operating speed for the "Horatio Allen" is 25 miles an hour with the limitation of 30 miles an hour. Mr. Edmonds also stated that notwithstanding these speed limitations which are strictly adhered to, this locomotive gets over the division much more rapidly than the other locomotives.

One of the speakers brought out the point that in all probability there should be no difficulty in using a double expansion engine such as the "Horatio Allen" with pressures as high as 350 lb., but when the pressure gets up into the range of 600 lb. to 1,200 lb. pressure, it was necessary to consider the utilization of a multistage engine and also to utilize those devices which would reheat the steam between stages as well. This, of course, means severe complication.

The opinion was also expressed that higher superheats are needed. One of the speakers who had some correspondence with the technical department of a locomotive building firm in Germany stated that this firm considered 660 deg. F. as a necessary steam temperature. In this country, the average temperature of 200 lb. pressure steam is 387 deg. F. By adding 300 deg. F. as recommended by the committee, a total of 687 deg. F. will be obtained

which is somewhat higher than the recommended German practice. It was suggested that the superheat of 200 deg. F. as recommended by the committee should be defined, whether an average or a maximum.

The chairman of the committee in replying to these remarks stated that to-day we are buying locomotives with supposedly 200 deg. F. of superheat, but are not getting over 135 deg. of superheat on an average, in freight service. The committee in pointing out that a higher degree of superheat than 250 to 300 deg. F., should be considered, was trying to indicate that at least 100 deg. more than has been obtained in the past should be the desired goal. The committee, he said, did not figure that this 300 deg. of superheat should be obtained by increasing the smokebox temperature abnormally, believing that good combustion means a smokebox temperature of probably 550 deg. F. and in addition, that the average superheat should come up to 225 deg. or 250 deg. and the maximum may go even as high as 350 deg. without any serious trouble.

In closing the discussion on locomotive development, one of the speakers advised the use of superheat at as high a temperature as lubrication will permit, because even though adding 100 deg. to the customary 200 deg. of superheat may increase the temperature of the exhaust steam 50 deg., there will still be a gain in efficiency because of the greater initial volume of the steam.

In the discussion of the sub-committee's report on water columns, it was suggested that the lugs of the water column shown in the drawing be changed from the horizontal hold type to the vertical hold type, as a number of the roads have experienced considerable trouble with the shearing of the bolts. As the recommended column was heavy, it was thought that the usual ½-in. or ⅝-in. bolts would not stand up. It was also suggested that as the bottom connection of the design shown was likely to be stopped up if any sludge accumulated on the bottom of the column, it might be preferable if that connection were made in such a way as to provide a mud pocket below the lower connection.

The point was also brought out that the manufacturers still have something to work out in connection with the construction of a force feed lubricator as none of them seems to have taken any definite steps toward providing an automatic means for controlling the temperature of the oil. This will have to be done before the force feed lubricator will become an ultimate success.

It was moved and seconded that the report be received and that the committee be continued for another year. The motion was carried.

Report on electric rolling stock

As a preface to last year's report, the committee offered under the title of Outline for Future Work, a general discussion of the economies of electrification as applied to existing steam operated railroads. Among the things exploited was the place held by the locomotive in railroad service with the possibility for more intensive operation and greater availability for service from motive power when proper study, planning and methods are applied. With that thought in mind it is well to consider means for obtaining maximum utilization.

A complete consideration must also include terminal electrification and the relative advantages of multiple unit train operation as compared with locomotive operation where such equipment is adoptable.

When the performance records of steam locomotives are reviewed over a considerable period of years with respect to availability for service, there seems to be indicated a retarding influence contemporary with the development of refinements and the increase in haulage capacity. These performance records further indicate that, whereas, the simple type of steam locomotive, as used some 25 years ago, was available for service approximately 75 per cent of the time, the modern steam locomotive seldom produces an average greater than 45 per cent. While obviously the addition of appurtenances and refinements, all of which improve the operating performance of the unit, will increase the amount of attention necessary to keep the locomotive in running order, yet, the decrease in service rendered cannot all be charged against such refinements. It would seem likely that a large percentage may be due to neglect in providing shop and terminal facilities in keeping with the requirements of the improved and larger power. Or perhaps the high percentage of unserviceable time may be due to a deficient understanding of the possibilities of the modern locomotive with its larger grate area, boiler dimension, general increase in proportions, and therefore greater margin of capacity as compared with designs of former years. Were these possibilities fully appreciated, then there would seem to be no logical reason for not providing and utilizing those facilities necessary for the prompt performance of shop and terminal work and thus obtain the maximum mileage performance between shoppings or terminal attention. Again precedent oftentimes places unnecessary restrictions on the realization of the wider range of service capacity of the modern locomotive, particularly where it is operated on the same division with power of a less recent design.

While it may appear inappropriate to dwell on deficiencies of the steam locomotive, nevertheless it is upon these deficiencies that great stress is placed by the proponents of electrification when the latter is under consideration. Such deficiencies should be taken into consideration by any road contemplating electrification and it seems only proper that cognizance be taken of them in this report. An outstanding advantage of the electric locomotive is the high percentage of serviceability as compared with the steam locomotive. Yet we cannot consistently compare them from this standpoint, unless provision is made for full utilization of the serviceability of which the modern steam locomotive is capable.

The steam locomotive of today is the product of many years of development with the view to simplicity and reliability with the result that the attainment of efficiency has been more or less sacrificed to that policy. Test locomotives have been built and successfully operated, under favorable conditions, whereby, through the utilization of stationary power plant practices, very high efficiencies have been obtained. However, it is quite doubtful that such types will become common, because the maintenance problem presented will greatly offset all other advantages. Generally speaking, the average thermal efficiency obtaining from steam locomotives is little greater than one-half that obtained by the operation of electric locomotives on power generated at first-class stationary plants, properly operated, and the advancement in this respect is more pronounced in the latter than in the former, because of the more favorable conditions. Restrictions as to space is not a factor, skilled operators may be employed with the view to obtaining high thermal and mechanical performance, and refinements in equipment may be instituted since the problem of maintenance does not exist in the same degree as in the case of the locomotive. The possibilities for high thermal efficiencies are very much limited in the case of steam locomotives; the opportunities in this respect are in nowise restrained when applied to stationary power plants of considerable size. However, it should be said in passing this point that the possibilities for sustained service with steam locomotives have not yet been attained and it can be said further that were the inauguration of a group of modern engines within a certain section attended with the same engineering skill and given the same support as is done when electrification is set in operation the results obtaining might prove more competitive with the electric power.

The trend of development for stationary power plants in the future undoubtedly will be toward higher initial pressures and temperatures with the object of obtaining higher thermal efficiencies. Such a tendency will have its effect upon electrification projects through a lower unit cost of power. This gain in efficiency will offset a part of the transmission losses or for the same overall efficiency, will permit longer transmission lines and in turn, the concentration of larger quantities of power in the individual plant or plants and of course fewer such plants.

As before mentioned, one of the pronounced advantages from electrification is the peculiar characteristic of this type of equipment which enables it to produce, under favorable surroundings, almost continuous service. Therefore, in laying plans for electrification, full recognition should be given this feature and traffic divisions, for one thing, should be so arranged as to permit long runs, or at least, continuity of runs that will make it possible to gain this advantage. Long mileage of electrified territory is, of course, favorable, but similar results can be accomplished by arranging for prompt return of power at the end of short runs.

The establishment of terminals and shop points has a great deal to do with making electrical operation economical. Repair facilities should be centralized in as few points as possible thus eliminating multiplicity of shop equipment and permitting the concentration of skilled workmen with a minimum capital outlay. Centralization of repairs within certain limits will react on the operation of the equipment to the extent of keeping it on the road,

whereas, with a shop too convenient there is always a tendency to hold the locomotive for minor repairs that can readily be handled at the inspection points. Electric locomotives are not subject to many disorders customary with steam power and in consequence repairs are not necessary at intermediate points. The terminal should be merely a dispatching point where but little work is done other than the ordinary running terminal inspection and such minor adjustments as may be found necessary. There is small need for machine tool equipment at terminal points, but it is advisable to have a liberal stock of small parts in order to make replacements when needed. Trains should be dispatched promptly with a view of keeping the power on the road with as little lost time at the terminal as possible.

Consideration must be given to the cycle of wear of the various mechanical parts and electrical equipment within each unit of motive power with a view of repairing or renewing such items as become necessary, thus keeping the locomotive in service for the longest period practicable. In this connection it is recommended that extra parts be kept in stock to the extent of providing major units such as complete running gears, traction motors, track units, etc., thus reducing the total of complete units to a minimum. The same may be said of multiple unit cars as far as maintaining complete major repair units is concerned. The situation is different however, to the extent that ordinarily the equipment reaches a repair terminal on each trip so that the inspection point and repair point in general coincide.

In the routine care of electric locomotives, a difference from steam locomotives is distinctly noticeable. A well designed and operated electric locomotive or multiple unit car, if properly inspected and repaired at periodic intervals, may be run between these intervals without any attention, except such inspection as may be necessary to determine that the car or locomotive is in a safe operating condition. The intervals at which the inspection and repair periods must be set can only be determined by operating experience and a careful study of the individual car or locomotive design, having in mind that careful inspection, with minor adjustments, will frequently prevent the necessity for extensive work. It is, therefore, recommended that facilities for testing and inspection of electric locomotives and multiple unit cars at periodic intervals be developed to a high degree, in order to obtain perfection in the operation, and thus reduce detention and intermediate inspection to a minimum.

Fullest utilization cannot be obtained, unless there is full cooperation between mechanical and transportation departments. The successful adoption of electrification requires a full understanding of its peculiar characteristics by all concerned. Educational measures should be inaugurated for this purpose and means for adequate instruction should be instituted sufficiently in advance that those having direct charge of the equipment may be fully acquainted with electrical matters and thus be able to handle the equipment in the best possible manner.

Where practicable, there is a great advantage in using locomotives of the same type for all services within a given district or territory. It will lend greatly to the flexibility of service, reduce the multiplicity of repair parts and operations, and be a large factor in gaining sustained service.

Official classification rule covering movement of gas and electric cars on their own wheels

During the year a special assignment was given the committee to study and recommend changed wording of Official Classification Rule No. 47. The rule now reads as follows:

Gasoline or electric motor cars, on their own wheels, gear wheels disconnected: Actual weight less fifty (50) per cent with a minimum net weight charge of 36,000 lb. each 5

Actual weight subject to minimum weight of 30,000 lb.

After due consideration of the features involved, the following wording was unanimously adopted as the proper wording of the rule:

Gasoline or electric motor cars, on their own wheels:

1st, *Self Propelled Cars Other Than Electric Driven*: Transmission or driving rods disconnected or transmission positively locked in neutral.

2nd, *Electric Motor Cars*: Not to be shipped with motors mounted on trucks:

Actual weight less fifty (50) per cent with a minimum net weight charge of 36,000 lb. each 5

Actual weight subject to minimum weight of 36,000 lb.

It is further understood that:

(a) No reference herein applies to electric locomotives or self-propelled cars shipped over rails on their own wheels and under their own power.

(b) Unless transmission or driving rods are disconnected as provided above, an attendant must accompany all such shipments. In any event it is recommended that an attendant accompany all such shipments.

The Rule as rewritten meets with the approval of both the Westinghouse Electric & Manufacturing Company and the General Electric Company.

Inspection rules

The sub-committee dealing with the subject of inspection rules of which J. V. B. Duer, electrical engineer, Pennsylvania, is chairman, is to continue without instructions until after the American Railway Association completes its conference with A. G. Pack, chief, Bureau of Locomotive Inspection, regarding new Interstate Commerce Commission inspection regulations covering ocomotives other than steam operated.

Shop facilities

As most of the heavier electrification projects have been attempted to handle some certain service condition or capacity, their detail operations have likewise been arranged best to meet the requirements. In consequence, the facilities have somewhat suggested themselves and have grown with the development of the undertaking. At the same time, with the introduction of electric equipment to work with or replace steam equipment, the essential additional features for the dispatching or running repair stations originally laid out for steam are not extensive. In a general way, facilities prepared for steam constitute practically or nearly everything needed for electric and more. At the general repair shops, the situation is somewhat modified and controlled by the type of equipment. In laying out new shops for either dispatching or general repair work, there may be conditions that might be re-arranged to considerable advantage to improve the order of operations and efficiency.

With the change from steam to electric power, it is in some cases more economical to use multiple unit passenger equipment in place of electric passenger locomotives. When this is the case the passenger car terminal repair shop should receive careful consideration, and will probably require a more radical change than that compared with the steam locomotive dispatching terminal.

Multiple unit equipment

There are certain tools necessary for the maintenance of electric multiple unit equipment that must be added to those usually found in steam road passenger car shops. The design of equipment used on multiple unit cars is limited to such extent that the tools and other facilities are practically the same for both direct and alternating apparatus.

The major tools should comprise armature banding lathes, coil winding machines, commutator slotting machines, bake ovens, presses, test apparatus for magnet coils, field windings, separate lathe chucks for boring and fitting up motor and axle bearings and small tools for air compressor and control parts.

Inspection sheds should be provided to handle the required number of cars, and equipped with suitable well lighted inspection pits.

One of the most important facilities required in a well designed back shop is a large crane equipped with special hooks for lifting car bodies off their trucks and placing them on temporary or shop trucks. While most any type of car or locomotive shop would probably be suitable for multiple unit equipment, the output depends entirely on efficient handling of the truck repair work. Therefore, traveling cranes should be provided with sufficient capacity to handle complete trucks. Sufficient floor space should be provided between truck repair tracks for piling of repair material for assembly.

Locomotive dispatching or running repair stations

Treating on the facilities for the terminal handling of equipment in contra-distinction to repairs in connection with dispatching and running repairs, steam equipment essentially requires provision for coaling, cleaning fires and ash pans, supply water, hot and cold water for boiler washing and filling boilers, steam blower to accelerate firebuilding, suitable inspection pits, and a turntable or wye to handle engines for return trips. Practically none of these are necessary for the handling of electric power, except inspection pits, sand supply, water for rheostats, where used, and provision for fuel oil and water for passenger locomotives using a steam boiler for train heating purpose. Consequently, in changing facilities for the exclusive handling of electric power, they may

be materially less than for steam. For the handling of steam equipment, as also applies to electric power, custom practically establishes one of the terminals reached in the course of the daily run or trip as the home or principal dispatching station. At this station, the major part of the running repairs is made, and in the interest of handling the work to advantage and economically, facilities are provided accordingly and in excess of those provided at the other terminals or outlying points. The facilities needed at outlying points for the handling of electric locomotives may be little more than inspection pits, and provision for sand and water supply, depending upon the type of equipment in use.

One idea of the comparison between the inspection and running repairs for steam and that needed for electric locomotives is that the former takes minutes for the inspection and hours to make repairs, while with the electric it takes hours to find the trouble and minutes to make repairs. These figures may be exaggerated, but serve to illustrate the reversal of the conditions.

The actual serviceable time of heavier steam power has been found to be in the neighborhood of 45 per cent as against 85 per cent for electric locomotives. This wide difference in serviceable time is no doubt due in part to the small amount of time required for the work on electric locomotives, in that complete units can be renewed in a comparatively short time. The longer time put on the steam locomotive is accounted for largely by the almost constant attention which must be given to the firebox, flues, stokers, guides, valve gear, reversing mechanism, piston and valve packing and periodic boiler washing and inspection. For electric locomotives inspection pits and means for supplying engines with sand and oil at outlying points are all that is necessary, except where passenger locomotives are handled means should be provided to supply oil and water.

For the handling of steam locomotives at the principal dispatching stations a turntable or wye is generally necessary to turn the power for the return run, and an engine house of the conventional circular form, with its turntable, well supplies convenience for the routine inspection and repair work. Similarly a turntable has been found valuable in connection with a rectangular engine house for the handling of electric locomotives composed of two or more units, and certain units of other types. By having a turntable or wye time can be saved by withdrawing for repairs but one cab or unit of a locomotive composed of two or more units, and the substitution of another cab to make up a complete locomotive, thus keeping the maximum number of complete locomotives in service, and at the same time handling the repairs on the out of order cabs to the best advantage. In making such exchanges and also to equalize flange wear, it often becomes necessary to turn a cab end for end.

Where electric power has been put in the field replacing steam either partially or completely, the complements of tools needed at the principal dispatching stations will be largely governed by the type of steam and electric locomotives used. Different methods of handling the running gear work at the outlying and principal stations in conjunction with operating conditions, set up problems that must be worked out or adjusted by the railroad to best meet the requirements.

A working pit supplied with a suitable drop pit for wheel and truck work is a convenience that might be considered common to steam as well as electric power, and is as convenient at the general repair shops.

An overhead crane of greater capacity perhaps than used ordinarily at a steam locomotive roundhouse is practically a necessity, for lifting motors, transformers, rheostats, air compressors, and other heavy parts of the electrical machinery from the frames, either through the hatch in the cab roof or after the cab has been removed.

The tool equipment must be distributed between the principal dispatching station and back shop, depending on the distribution of the repair work between the principal dispatching station and back shop as well as on the relation of the shops and whether the principal dispatching terminal is constructed in combination with the back shop or as separate shops located some distance apart.

To handle the work on electric equipment at the dispatching station comparable with the work that would ordinarily be necessary on steam equipment the demands are nevertheless different, and the conditions might be better pictured by considering that in place of the locomotive boiler, steam cylinders, guides, crossheads and valve gear on the steam locomotives, the electric locomotive carries motors, phase converters, control apparatus, rheostats, switches and relays. In place of the steam locomotive cross head, certain types of electric locomotives have the jack shafts, gears or spring quills through which the power of the motor operates the locomotive. On an electric locomotive having the same general type of steam locomotive frame and wheel arrangement, the driving boxes, shoes and wedges, and brake rigging are practically the same. The side rods on an electric locomotive are practically the same as on the steam locomotives.

For electric locomotives having gear drive and motor armature mounted on the driving wheel axle, the maintenance work on the gear in a general way takes the place of operations corresponding to side rod maintenance. However, the total equipment necessary may be different.

The machine tools required at a steam locomotive dispatching station to maintain such parts would be practically the same for electric, and in the interest of handling the work to advantage, it has been found convenient to have at the principal dispatching stations tools such as a boring mill suitable for driving wheel centers and tires, a lathe of sufficient capacity to swing the largest motor revolving part, a 24-in. lathe, an intermediate size lathe for smaller motor repair work, a radial drill press, a slotter, vertical drill press, horizontal boring mill for bearings and bushings, press for removing and applying motor shafts and shaper, and facilities for repairing switches, relays, instruments, circuit breakers, etc.

For the major repair work which must be handled at shops corresponding to what are generally understood as back shops or shops where general repairs are made, some inexpensive changes might be made in arrangement of facilities and tools in an existing steam locomotive shop for the same general character of work on electric locomotives to improve the sequence of operations, as they differ somewhat between electric and steam power.

The boiler shop equipment can be eliminated, with the exception of a few tools for the rebuilding and repairing of transformers, rheostats, water and oil tanks and small boilers used on electric locomotives in passenger service.

In most steam locomotive repair shops, overhead cranes have been provided of sufficient capacity to lift a complete locomotive. A crane of sufficient capacity to lift a complete electric locomotive or one cab or unit composing an electric locomotive is desirable, where the design permits, though not always as necessary or as useful as for the handling of a steam locomotive. A crane, however, is quite necessary for the lifting of certain electric parts such as motors, transformers, phase converters, rheostats, and other heavy parts from the frames either through an opening cut in the roof of the cab, or after the cab has been removed. Under the crane should be provided a well lighted working pit, supplied with a suitable drop pit for driving wheels, removing main motors, truck, brake rigging work and similar work on the running gear.

There are many tools in use in the steam locomotive repair shop that might be well utilized in the maintenance of electric equipment, although on account of some of the electrical apparatus being rather special, there may be a demand for a greater number of small tools of special arrangement and design in order to handle small parts of motors, switches, blowers, etc. For instance, a boring mill for driving wheel centers and tire work, a lathe of sufficient size to swing the largest armatures or motors, small as well as intermediate size lathes, a radial drill press, a vertical drill press, a horizontal boring machine, a planer, a shaper and a driving wheel press should be provided. Lathes ordinarily used for piston work can be used for small motor shaft work. The smaller lathes and shapers can be used on a quantity of smaller electrical parts; maintenance of air compressors, dynamos, air brake work and other auxiliary units forming a part of the electric locomotive.

In addition to the equipment usually found in a well equipped locomotive shop, facilities must be added for armature banding, coil winding, press for handling armature shafts, etc. The armature and control repair department should, if possible, be conveniently located adjacent to the machine shop in order to make the best use of the crane service and minimize the re-handling of motors and especially armatures on motors.

As a rule, existing steam locomotive shops, with some slight rearrangement of facilities, are very adaptable for the care of electric locomotives. There are, however, great possibilities for economies in labor and time where new shops are designed for the exclusive care of electric equipment. A definite layout or

complement of tools cannot be prescribed, as both depend entirely upon the general design of equipment used.

Electrification progress

Progress made in the electric traction field during the past year was included as Exhibit No. 4. The new types of motive power units built were commented on and a large table included which lists electric traction installations used in all the principal countries of the world. This table includes a group of pertinent facts which characterize each installation.

A report listed as Exhibit 5 compares the relative advantages of the multiple unit system and electric locomotives for passenger service.

On motion, the report was accepted and the committee continued.

Committee on car construction

In connection with this report, attention is directed to the samples of cars and car equipment, displayed to illustrate features included therein.

The various subcommittees have done excellent work, especially that on box cars with wood sheathing and lining, and that on fundamental design calculations. The last mentioned report could not be condensed without loss of valuable information, for which reason it is included complete, as an appendix to this report.

Standards and alternates

For the purpose of simplification, and to avoid misunderstandings it was decided that only one design of complete unit or detail, not patented, if possible, would be used to illustrate a standard or recommended practice. Any other designs, either shown or implied, would be known as acceptable alternates.

A note will be included with the drawings or specifications for same to govern cars built from the design, reading as follows:

Anything that is shown on the drawings as alternates, indicates that such alternate is equal to that shown, as standard or recommended practice, in strength, service, and interchangeability, and, therefore, acceptable.

It is to be understood that the committee designs establish fixed conditions, permitting the use of detailed designs standardized by the association, or the substitution of other parts preferred by the individual railroad, singly or in groups, provided these parts, or groups of parts, are the equivalent in strength, service, and safety of, and interchangeable with, the standard part or group of parts replaced.

The subcommittee on Car Designs have adopted rules governing the size and marking of tracings which will be followed in the future.

Trucks

The general plans show the frames adopted as recommended practice, with minor unimportant modifications, to facilitate foundry work.

The side frames, with boxes cast integral, have been shown as representing recommended practice. The Andrews type and special box type, also cast or built-up types, which will meet design and specification requirements and are interchangeable, are acceptable alternates. The special box types have been previously shown, but new tracings, incorporating the slight modifications for foundry practice, made in the integral box type frames, will be made for the manual.

The bolsters illustrated conform closely to those now in the manual and to the present A. R. A. fundamentals. Other bolsters meeting the design and test requirements are acceptable, if interchangeable.

The bolsters now in the manual do not conform to the standard fundamentals, which makes them obsolete. It is, therefore, recommended that they be withdrawn, and the new bolsters substituted therefor.

The subcommittee on Trucks is investigating what changes are required in the standard arch bar design, to meet the design and specification requirements referred to.

To provide truck frame information, as complete as possible, a subcommittee on Frame Tests is preparing to test A. R. A. and U. S. R. A. frames in three ways: First, on screw-operated static test machines, with both vertical and transverse loads, in conformity with the proposed specifications; second, on the American Steel Foundries Company dynamic test plant, and, third, on the Symington dynamic test plant. It is expected that a summary of these tests, and an analysis thereof, can be presented next year.

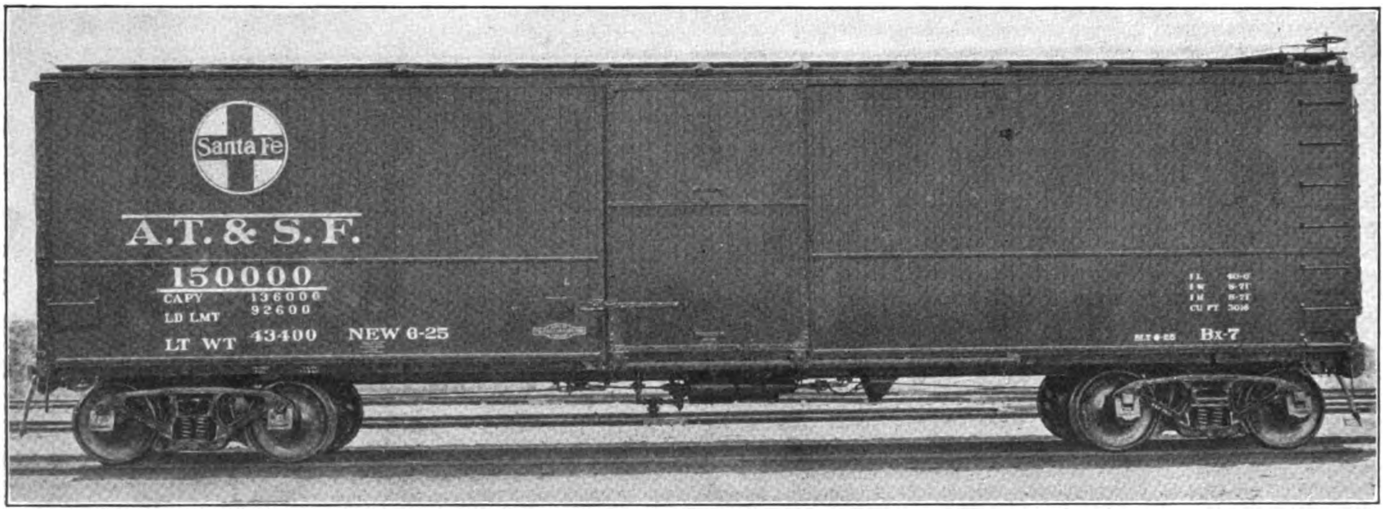
Designs for standard cars

Single-Sheathed Cars—These designs, including specific modifications, were adopted as recommended practice. New tracings are being prepared to include the modifications, and will be available later in a supplement to the manual.

Steel-Sheathed Cars with Wood Lining—The committee was instructed to await service results of those already built before resubmitting this to letter ballot. Nothing further has been done with this design.

Steel Frame Cars with Wood Sheathing and Lining—These designs, covering cars of 40 and 50 tons capacity, have been carefully considered by a subcommittee, and are presented for adoption as recommended practice.

These designs include the changes in the original fundamentals, which were adopted by letter ballot vote on the single sheathed car. The fundamentals and general specifications for A. R. A. box cars, as shown in the manual, have been observed throughout.



Double wood sheathed 40-ton box car, class 4C-XM2, with proposed standard lettering and marking

1—In accord with the modifications adopted by the association for the single sheathed car, the length over striking castings has been reduced from 42 ft. 6 in. to 42 ft. 3 in. This was done in order to avoid having an excessive end ladder clearance when a pressed end is used, and reduces the truck centers from 32 ft. 6 in. to 32 ft. 3 in., with a consequent reduction of ¼ in. in the width of each truss panel.

2—As recommended by the subcommittee on Fundamentals of Design, the crossbearers have been relocated at the door posts, instead of at the intermediate posts.

3—A combined striking casting and front draft lug has been designed to replace these two details. This results in a saving of 6½ in. in length of center sills.

4—A new corner construction has been developed for this car, using a 3½ in. by 4⅛ in. by 3½ in. Z-bar for corner posts. This construction permits of the use of either the A. R. A. standard steel plate end or a pressed end, with the same corner post. The pressed end construction with its constituent parts, i.e., end sheets, end plate, side and end plate construction, end sill and push-pole pocket, taken as a group, is interchangeable with the A. R. A. end plate.

5—In order to avoid cramping the hand brake rod where it passes through the bolster diaphragms, it was necessary to redesign the body side bearing brace so that the hole for rod could be moved further from center of car. A casting was substituted for the pressing shown for single sheathed car.

6—The design of the side door has been changed to give more substantial construction.

7—A door track has been added to bring the roller more clearly over the center of gravity of the door. This track is a 1¾ in. by 1¾ in. by 1¼ in. by 1¾ in. Z-bar and serves also as a guide. A bottom supported door can be used without disturbing this top guide, and the bottom guides and the side sill filler supports are so arranged that the track for the bottom supported door can be applied without any additional punching of holes in the side sill.

8—In order to increase the ease of operation, the door hanger has been redesigned, using a 3½ in. instead of a 2½ in. roller.

9—The latitudinal running board supports have been redesigned so that the same support can now be used with either the outside metal roof or the all-steel roof.

10—Due to the location of crossbearer at the door post, it was necessary to change the brake arrangement. The cylinder and reservoir were moved 3 in. toward the center line of car. Various details were also simplified. The K D type of brake arrangement has not yet been developed.

11—The brake shaft was lengthened about 1 in. in order to give 5½ in. hand wheel clearance.

Consideration was given to all suggestions and criticisms received from nearly all members of the Committee on Car Construction, and also from the Railway Car Manufacturers' Association.

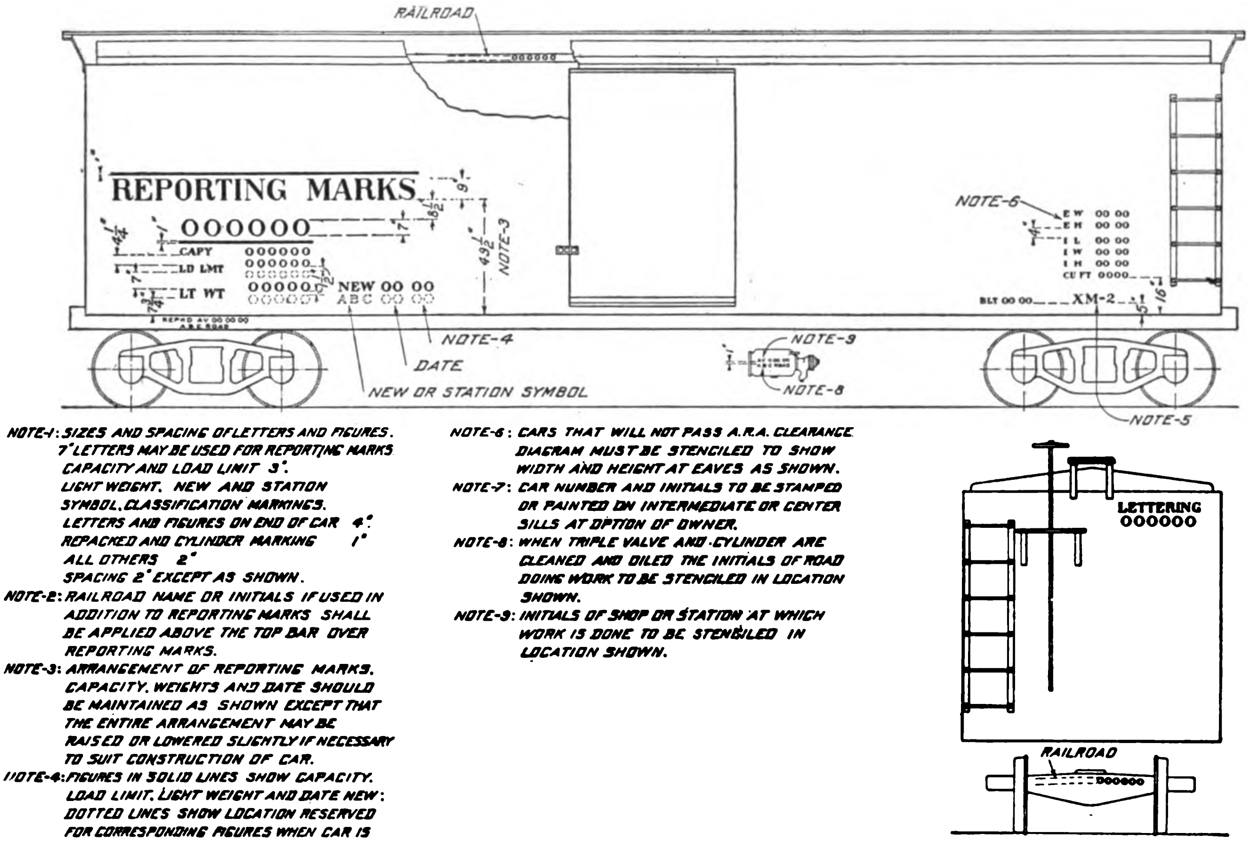
While it has not been practicable to use a number of details of the single-sheathed car on the double-sheathed cars, new details have been developed which may be used on both designs.

We wish to call attention to the method of making the post and brace connections at the side plate. The outer legs of the Z-bar post and brace are turned toward each other, and a plate is riveted on the inside, the rivets being countersunk on the outside to give a smooth surface for the application of the sheathing. The outer legs of the post and brace are riveted to the gusset plate which is flanged at the top, and riveted to the horizontal web of the side plate, instead of to the vertical leg. With this construction, the Howe truss, which is an alternate, may be applied without any interference with the carlines on the outside metal roof. This construction also tends to eliminate the eccentricity in the posts.

The subcommittee will prepare a Safety Appliance drawing for publication in the Manual after the Interstate Commerce Commission representatives have had an opportunity to inspect the sample cars and criticise the application of safety appliances. Any suggestions the Commission may make can then be incorporated in the drawing.

Fundamental calculations

In the absence of reliable information covering strains or stresses exerted on cars, and methods of calculation to design parts to



Proposed standard lettering and marking of box cars

resist such strain in the car body, it was deemed desirable to appoint a subcommittee of experts in this work to furnish a complete synopsis for our future guidance. This subcommittee, after a large amount of very painstaking and careful work, has produced a valuable addition to the available information on car design. Their report is given in an appendix.

Specification fundamentals

One of the functions of the committee on Car Construction is to indicate fundamentals on which specifications should be prepared. The trucks and other important car parts can best be safeguarded by specific designs and tests predicated on standard fundamentals. The test should prove the correctness of the design.

This committee will, from time to time, present for approval such design and test requirements, and now submit for adoption as Recommended Practice, Design and Test Requirements for Truck Side Frames and Bolsters, also Coupler Yokes. These have been fully discussed with the representatives of the manufacturers.

It is recommended that, after the adoption of these requirements, the committee on Specifications and Tests be instructed to prepare the necessary detail specifications.

Side Frames and Bolsters—They may be either integral or built-up. The maximum combined unit stress in the design shall not exceed 16,000 lb. per sq. in. The basis of design shall be one axle capacity=C.

For each side frame the vertical design load shall be taken as acting on the spring base (or its equivalent, for test) and shall be 1½C. The transverse load shall be taken as acting on the bolster guides—one-half on each guide—on a line located above the normal center line through the two axles, an amount equal to the journal diameter of axle less 1½ in., and shall be 0.4C.

For each bolster the vertical load shall be taken as acting on the center line of the bolster, anywhere within 8 in. each side of the center bolster; also anywhere from the center of spring support to a point 23 in. from the center of bolster. The section moduli shall decrease uniformly from the section 8 in. from the center to the section 23 in. from the center of bolster.

The transverse load shall be taken as acting on the neutral axis (or, for test, on a line 5 in. below the center plate bearing face), and shall be applied only at the center of bolster.

For calculation of maximum combined unit stress, the vertical load shall be equal to P, as given in the table, and the transverse load shall be 0.25P.

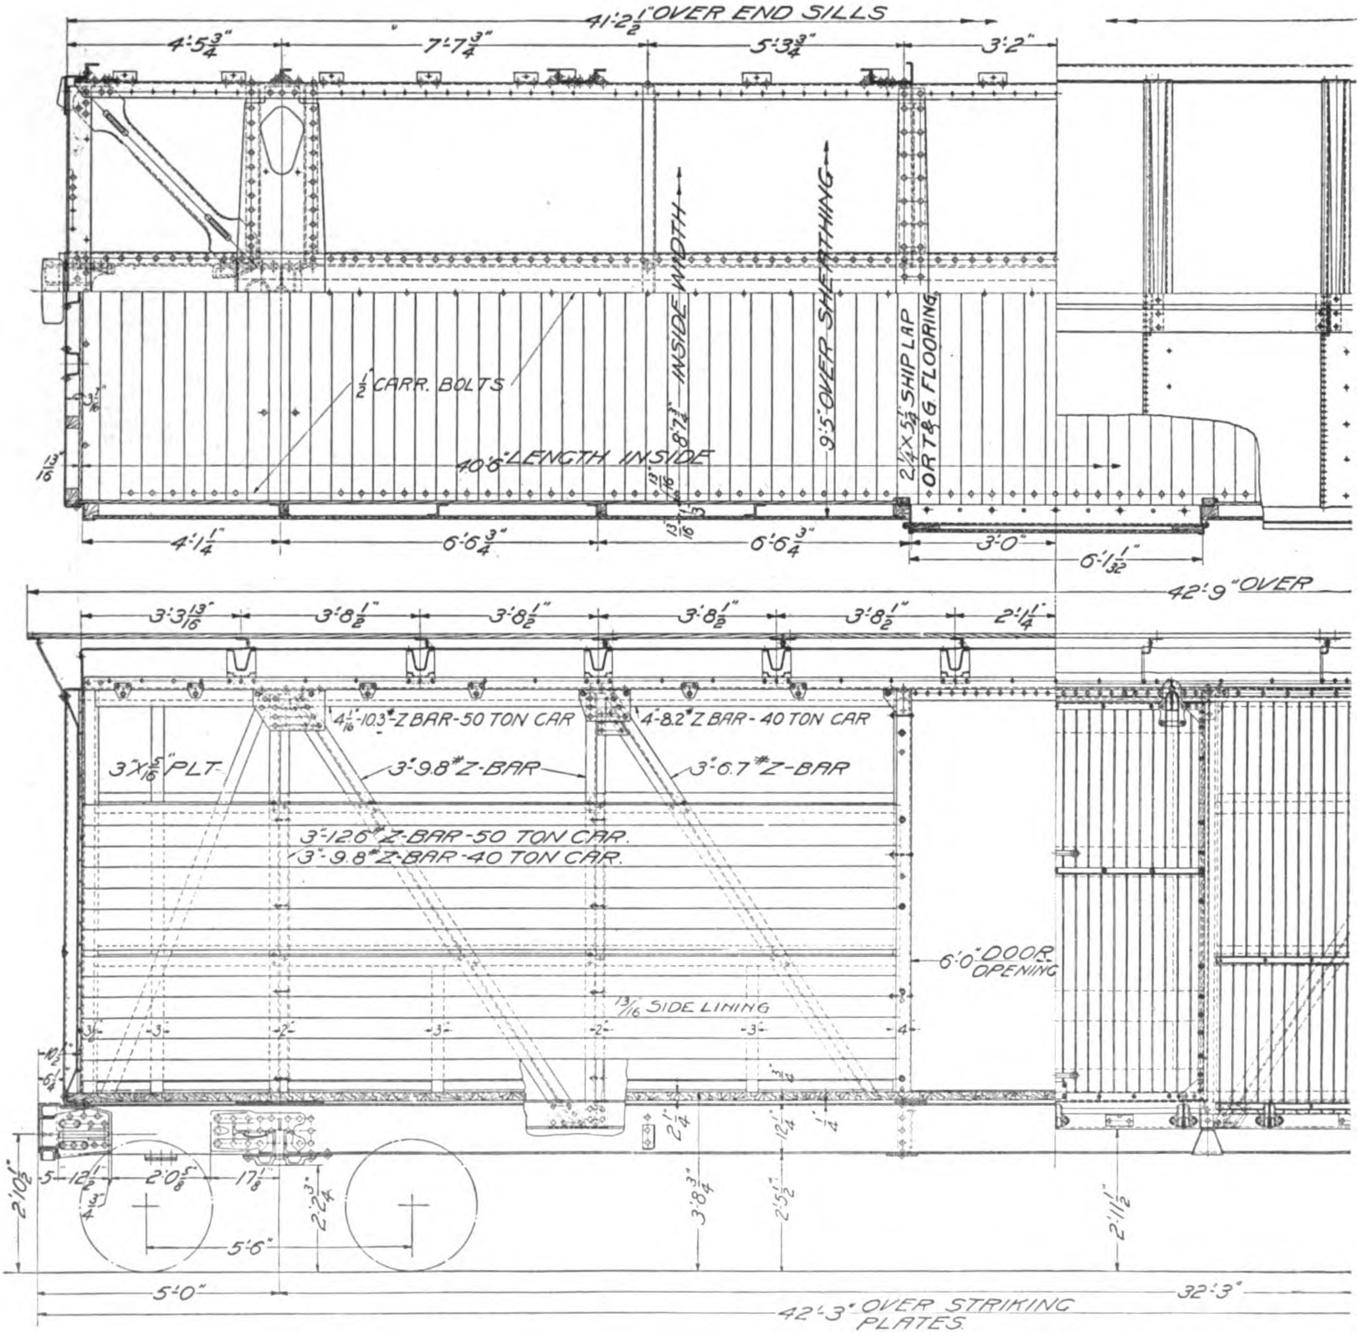
The maximum unit stress for vertical or transverse loads, considered separately, shall not exceed 12,500 lb. per sq. in. for vertical load=P, or horizontal load=0.8P.

The values for P are as follows:

Truck	P
2C	62,000
2D	77,000
2E	96,000
2F	115,000

Test load requirements

	Side Frame		Bolsters	
	Vertical lb.	Transverse lb.	Vertical lb.	Transverse lb.
Initial load or zero reading........	5,000	5,000	5,000	5,000
Load at 0.063 in. max. deflection...	2.25C			
Load at 0.075 in. max. deflection...			1.5P	1.00P
Load at 0.094 in. max. deflection...		0.60C		
Load at 0.031 in. max. permanent set	4.50C	1.20C	3.0P	2.00P
Minimum breaking load	9.00C		6.0P	



General drawing of proposed standard A. R. A.

Bolsters shall be accepted if the minimum breaking load exceeds 90 per cent of the tabulated amount.

The vertical loads, "P," for bolster, shall be applied separately, at center plate, and at side bearing.

The deflection measuring instrument shall be located midway between supports of specimen, and shall be set at zero, under initial load.

Coupler Yokes—They shall be made of cast, forged, or rolled steel. Each coupler yoke design, intended for use with type "D" coupler and 6 in. by 1½ in. key, shall meet the following design requirements and tests: If made of Grade "A" cast steel, or its equivalent, the tension area shall not be less than 12 sq. in.; and, if made of Grade "B" cast steel, or its equivalent, the tension area shall not be less than 10½ sq. in. The method of support and loading shall be equivalent to service conditions on tangent track. The maximum set shall not exceed 0.031 in. under a load of 325,000 lb., and the breaking load shall not be less than 550,000 lb. The set shall be taken in the length, from the rear follower bearing face to the front coupler key face. At least two specimens of each new design of coupler yoke shall be tested on a static testing machine.

All standard fundamental A. R. A. requirements not specifically mentioned herein shall also govern.

Truck Springs—Many serious complaints have been made as to spring troubles. The cause of the trouble is due to spring manufacture practices. These practices will have to be revised, at least to some extent. A large proportion of springs examined by micro-photography show decarbonization, on the surface of the wire, to a marked extent, indicating overheating in manufacture. The low stress in springs, when solid, evidently permitted these detrimental practices to develop. Springs properly made can readily be stressed from 25 per cent to 50 per cent higher than according to present practice.

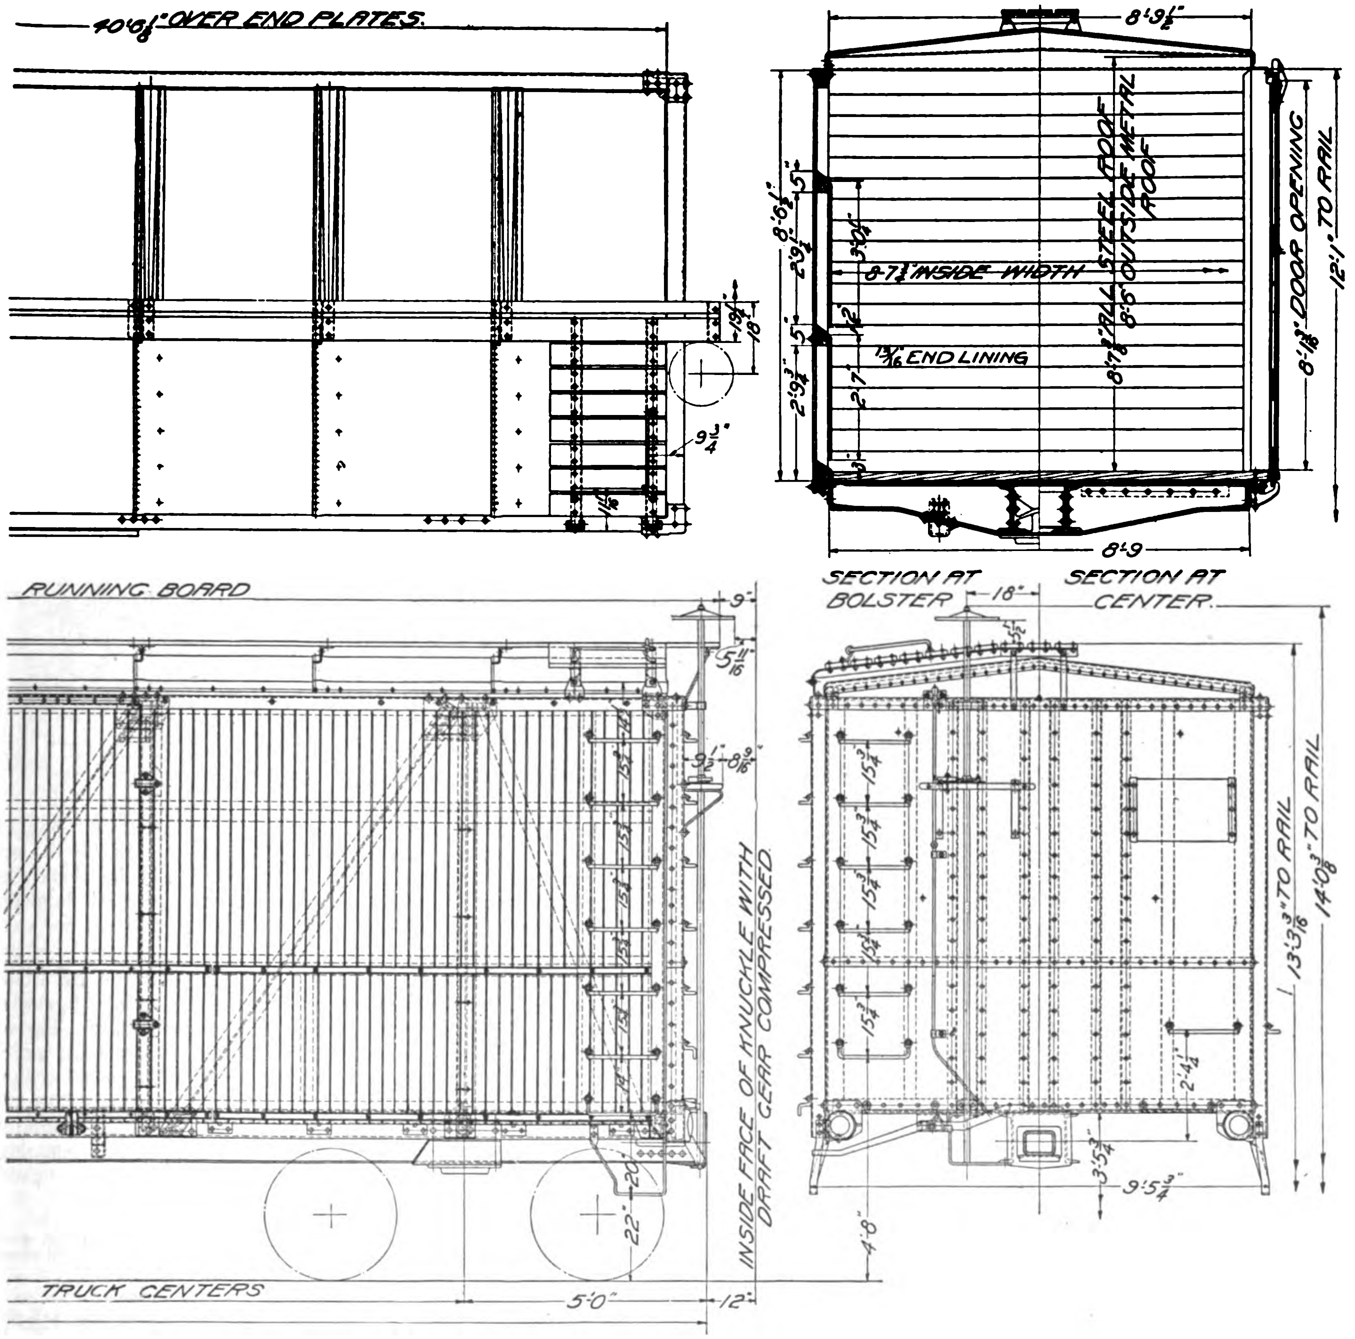
It is unanimously recommended that:

1—The tentative spring designs, class L, M, N, O and P, shown on pages 34 and 35, section D, of the manual, shall be substituted for the present standards shown on pages 27-37, in section D.

2—The tentative specifications for Chrome Molybdenum alloy steel helical springs shall be withdrawn.

3—The standard specifications for carbon steel bars for railway springs shall be modified to require free height not to exceed, and the height under specified load, not to be less than the design heights.

4—The substitution of the present standard 50-ton car springs, as shown



double wood sheathed box cars, classes 4C-XM2 and 4D-XM2

on page 32, section D, of the manual for springs of the new standard 40-ton cars, shall be permitted.

The changes involved in the recommended modifications will make no changes in existing trucks, will incur no increase of stress in the springs under static load, will require no different material either in quality or dimensions; but will materially decrease shock effect, thereby benefiting both the springs and truck frames.

It is recommended that, after the adoption of the above, by letter ballot, when it is referred to the Committee on Specifications and Tests, to prepare the necessary change in the specifications, they should, if possible, include a surface decarbonization limit, and such other photo-micrograph requirements that they deem proper to insure careful heat treatment.

Hatch Covers for Refrigerator Cars—It has been suggested that considerable expense could be avoided if a standard hatch cover be adopted, and all new cars be made to use that standard. A subcommittee made a full investigation of existing cars, and reported that it would be practical to adopt one standard. They submitted a design of hatch opening and cover advising that this design is adaptable to the greatest number of existing cars, without serious modification to the cars, and will be satisfactory for new equipment. Your committee recommends the adoption of this design as a standard of the association.

Corrections.—Attention was directed to an apparent error in dimensions for the gages for the 4¼ in. by 8 in. bearings and wedges. The criticism is justified, and corrections should be made.

box car ends which meet the A. R. A. requirements of section "C," pages 7 and 8, are not as serviceable as they should be; also that comparing ends on the basis of section moduli is not a measure of relative service value, on account of differences in elasticity.

During the coming year a subcommittee will make a thorough investigation of this subject by making a series of tests to destruction of the generally used corrugated ends, and the A. R. A. steel end with vertical posts. The preliminary instructions to the subcommittee include:

1—All tests shall be made on full-size samples, exactly as applied to a car.

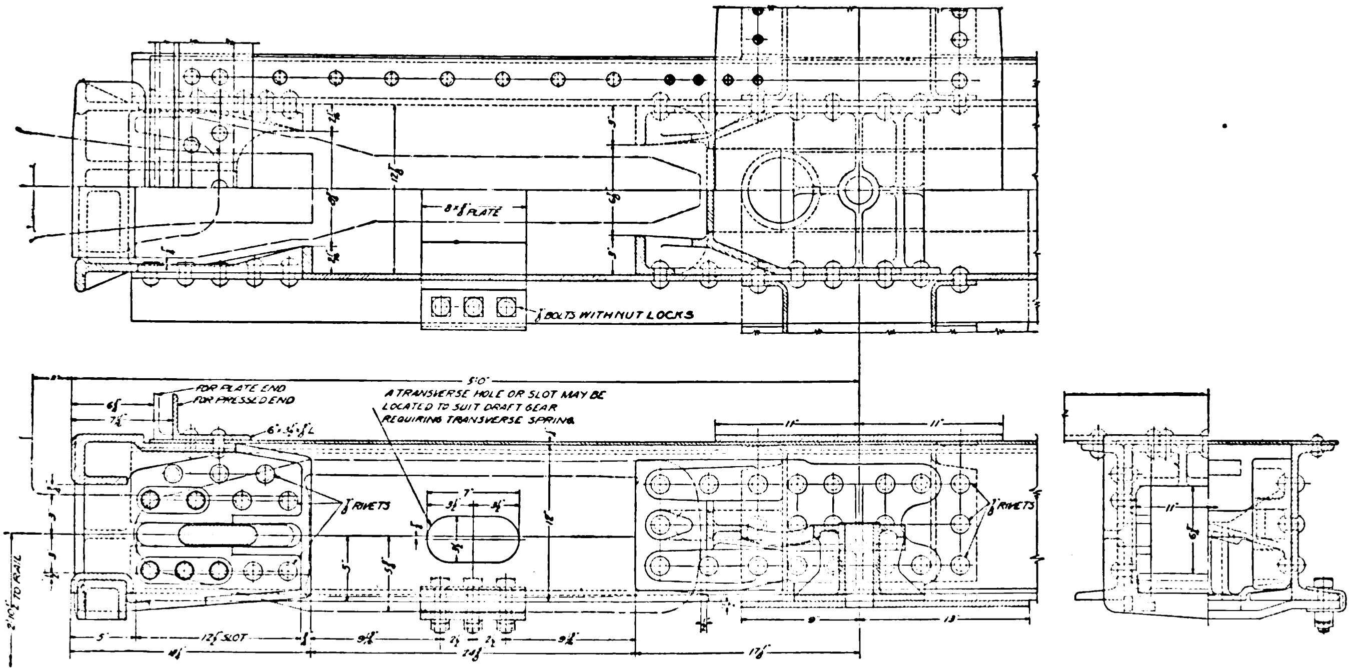
2—Ends to be tested shall be the Murphy corrugated end, and the A. R. A. steel plate end with vertical posts.

3—Ends to be tested shall include the lining and side post construction.

4—The side post construction shall be the same as used on the car, and so reinforced that these posts are not subject to material deflection.

Axles—It was requested that the non-standard axles having 4 in. by 7 in. and 4½ in. by 8 in. journals be recalculated on the basis of the A. R. A. formulæ, to determine whether the nominal capacity can be increased. This calculation showed that the axle with 4 in. by 7 in. journals, under a car with a load limit of 87,000 lb., would produce a stress of 29,520 lb. per sq. in., at the hub section. Therefore, the load limit should not exceed 67,000 lb., to meet the unit stress limit of 22,000 lb. per sq. in. For this axle no change is recommended.

The recalculation for the axle with 4½ in. by 8 in. journals,



Draft gear arrangement with combined striking casting and draft lug

We, therefore, recommend the following changes: Section D, page 25, wedge "B," change dimension "D" from 2 11/32 in. to 2⅜ in., and dimension "N" from 4 1/16 in. to 4 3/32 in. Section "B," page 23, wedge "B," change dimension "D" from 2 11/32 in. to 2⅜ in., and dimension "N" from 4 1/16 in. to 4 3/32 in.

There is a similar discrepancy in journal bearing gage, section "B," page 22, for class "F" bearing. The ½ in. dimension, at each end, should be changed to ⅝ in., for the "F" bearing only. We recommend that this be done.

There is a discrepancy in the dimensions of the cap for class "H" spring. To make the correction, we recommend that in section "D," page 33, cap for class "H" spring, the dimensions locating the tests be changed from 3 in. to 3 5/16 in., and that the depression for the bolt be made the same as for capacity for class "E" spring, page 35, section "D."

Gages shown on pages 17 to 21, inclusive, of section "B," of the manual, are still standard. They have been practically superseded by gages shown on page 22 and 23, of section "B," which were adopted as Recommended Practice in 1921. We recommend that the latter gages be advanced to standard, and that the old standards on pages 17 to 21, inclusive, be eliminated.

Box Cars (Progress Report)—The claim has been made that

when the minimum wheel seat diameter is increased from 5⅝ in. to 5¾ in., will meet the unit stress limitation of 22,000 lb. per sq. in. under a car load limit of 116,000 lb. It is, therefore, recommended that for this axle the minimum wheel seat diameter be increased to 5¾ in., and the load limit be 116,000 lb., for cars equipped with such axles.

Lumber for Cars—The United States Department of Commerce, by the Central Committee on Lumber Standards, has been active in producing new standards of dimensions and grading of lumber, for the purpose of eliminating waste by simplified practice. We have been requested to make our requirements for cars dovetail with their proposed standards, as far as possible. A careful review of what we need, and what the Central Committee on Lumber proposes to adopt as standard, has led to the appointment of a subcommittee to handle this subject. It was unanimously decided to instruct the subcommittee to ask for:

1—Lumber dressed to 13/16 in. thickness for lining and sheathing, and, if that cannot be obtained as standard, then request for ⅞ in. thickness (dressed), as standard.

2—Lumber, dressed on one side, 2⅝ in. thick, for flooring.

3—Lumber 2 in. nominal rough thickness, manufactured so that the greatest thickness is obtained when dressed on one side; this lumber to be used where 1¾ in. is now specified for light flooring.

Moisture content in lumber used for cars is of primary importance, and we have been urged to provide a specification giving as low a percentage of moisture as can reasonably be expected under conditions that must be recognized, and at the same time insures the use of material which will not cause trouble from excessive shrinkage. We recommend as a requirement for lumber in car construction the following rules for percentages of moisture content in lumber at time of application to car:

DESCRIPTION	NOT TO EXCEED
Up to 1 in. thick	10%
Over 1 in. and up to 2 in.	12%
Over 2 in. and up to 3 in.	15%
All over 3 in.	20%

For sheathing of single sheathed cars, regardless of thickness, moisture shall not exceed 10 per cent. The moisture remaining in the lumber entering into the car shall be determined by taking as 100 per cent the weight of the test samples, after they have ceased to lose weight.

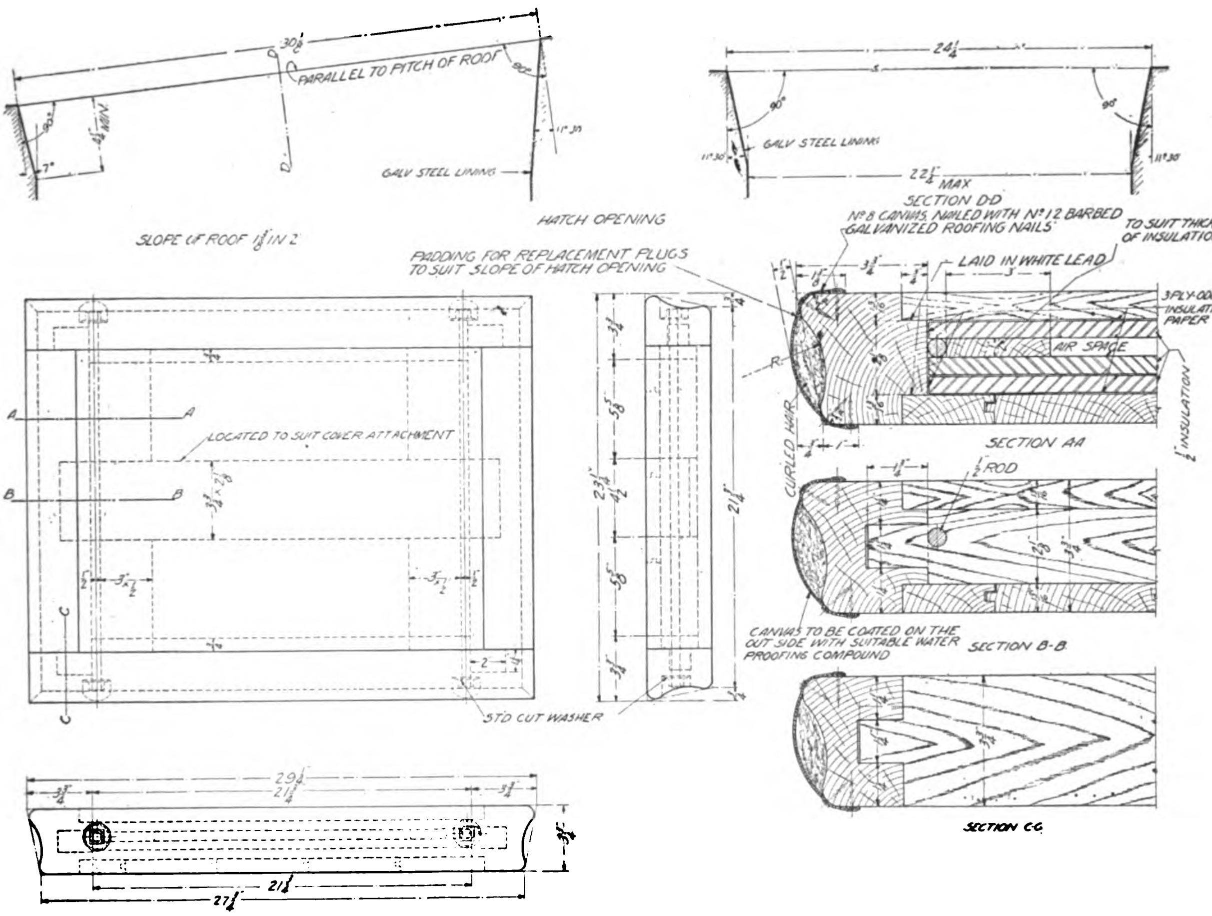
These recommendations, if carried out, will be a move in the right direction to secure better construction, and while the percentages are more liberal than some roads may wish to specify, ance of such material, it is intended to indicate its value, based on the specifications, relative to steel and iron castings.

Lettering and Marking Cars—In developing designs for new cars it was noted that the present standard lettering and marking of cars as shown in the manual includes triple valves, coupler shank, coupler attachment, brake beams and size of journals, all of which parts are covered by Interchange Rule No. 3 for cars built after November 1, 1920, and it therefore appears unnecessary to include such parts in the marking of cars built after that date.

It was further suggested that the markings for length, width and height could be greatly abbreviated and that height and width at eaves would only be necessary for cars that will not pass the A. R. A. clearance diagram.

In connection with Rule 86, the Executive Committee now has before it a recommendation approved by the Transportation and Mechanical Divisions covering capacity, load limit and light weight marking in place of the former capacity and weight marking. (*See report of General Committee.*)

The committee submits with this report a drawing which embodies all of the preceding suggestions and in addition omits the



Proposed standard hatch plug and hatch opening for refrigerator cars

they form a basis for trial that should develop whether further modifications are desirable and are so submitted with recommendation for adoption as Recommended Practice by letter ballot.

Malleable Iron Castings (Progress Report)—Requests have been received that we reconsider the elimination of the use of malleable iron for a number of items embodied in proposed standard car designs.

The standard A. R. A. specifications for malleable iron castings are practically obsolete, since metal produced by this process, at present, would permit minimum requirements greater than those specified.

Our rules now permit the substitution of changes in design and material for those given, provided they are equivalent in strength, service, and safety of, and interchangeable with, those replaced.

As soon as an agreement can be reached with the advocates of the more extended use of malleable iron castings, relative to the best specifications that can be formulated to govern the accept- railroad initials on inside of doors and adds railroad initials on inside of side plate.

The committee recommends the adoption of this proposed marking for:

(A) All house cars built new hereafter.
(B) For repainting house cars built new after November 1, 1920.
(C) Repainting all rebuilt cars which conform in all respects to the requirements of Interchange Rule No. 3 for new cars.

The report is signed by W. F. Kiesel, Jr. (Chairman), mechanical engineer, Pennsylvania System; A. R. Ayers (Vice-chairman), assistant general manager, New York, Chicago & St. Louis; O. S. Jackson, superintendent motive power & machinery, Union Pacific; C. L. Meister, mechanical engineer, Atlantic Coast Line; J. McMullen, superintendent car department, Erie; John Purcell, assistant to Vice-president, Atchison, Topeka & Santa

Fe; W. O. Moody, mechanical engineer, Illinois Central; J. A. Pilcher, mechanical engineer, Norfolk & Western; F. H. Hardin, chief engineer motive power and rolling stock, New York Central; C. B. Smith, mechanical engineer, Boston & Maine; S. O. Taylor, master car builder, Missouri Pacific; Ira Everett, general car inspector, Lehigh Valley; W. A. Newman, mechanical engineer, Canadian Pacific; G. S. Goodwin, mechanical engineer, Chicago, Rock Island & Pacific; F. W. Mahl, director of purchases, Southern Pacific; J. J. Tatum, superintendent Car Department, Baltimore & Ohio; L. K. Sillcox, general superintendent motive power, Chicago, Milwaukee & St. Paul.

Discussion

W. F. Kiesel, Jr. (Penna.), chairman of the Committee on Car Construction, stated that in the design for the double sheathed wood sheathed cars only one type of center sills is shown suitable for vertical yoke. It was agreed two years ago, he said, that center sills suitable for both types of yokes should be shown. In making the design for the single sheathed cars, the same center sills that are shown for the wood sheathed wood lined car and also the center sills for the horizontal yoke, which will be applicable to either one of the other cars, will be used.

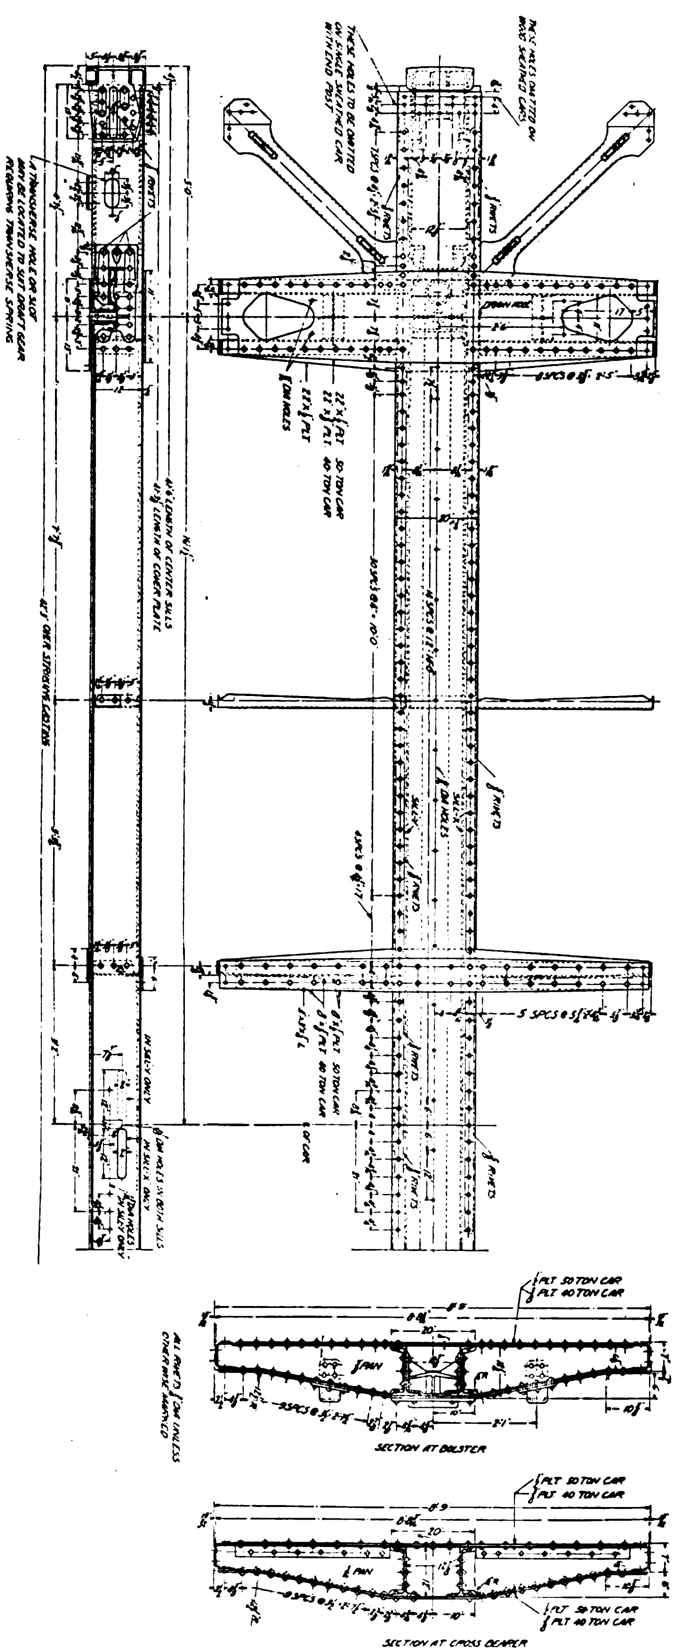
In discussing the strength of the truck frame adopted as recommended practice, J. J. Tatum (B. & O.), a member of the truck sub-committee, stated that it is planned to run comparative tests with 40-ton and 50-ton Railroad Administration side frames and with 40-ton and 50-ton A. R. A. side frames on the Symington testing machine and also on a machine which produces similar tests at the American Steel Foundries, St. Louis, Mo. To overcome the failures of the present A. R. A. arch bar truck, he said that it was thought that the truck sub-committee of the Car Construction Committee might design an arch bar that could be used in repairing the existing trucks so that the weakness of the original design could be overcome and at the same time the additional load that the new Rule 86 and the new marking permits in the car be provided for. Mr. Tatum then referred to the two B. & O. cars on exhibit during the convention, one of which is equipped with a Washburn truck and the other with a somewhat similar truck* which is free from nuts, bolts, washers, keys or pins except for brake pins.

A number of questions were asked relative to the procedure to be used in testing the side frames. It seemed to be the consensus of opinion that the standard A. R. A. static machine as well as the Symington and the American Steel Foundries testing machines should be used, and that comparative tests between the proposed arch bar truck and cast steel side frame trucks should be made.

The point was brought out that the trussed bolsters which had been used extensively on some railroads will not meet the test requirements as specified by the committee. The design with the specifications for side frames and bolsters was made so that under a combined load the maximum stress would not exceed 16,000 lb. per sq. in. This will give a factor of safety of approximately four. Under a direct vertical load it is shown in the specifications that the factor of safety is about six. It was suggested that possibly some modifications in design should be made to find whether or not trussed bolsters could not be made to meet the test limits. If not, and there was a good reason why trussed bolsters should not be subjected to the same specifications, it was stated that the committee would be glad to get any constructive criticisms and, if necessary, produce another specification that would take into account the difference in construction.

One of the speakers in discussing the design of springs recommended in the report, referred to a number of tests made at Ashtabula, Ohio, by the New York Central, with the assistance and co-operation of the Chesapeake & Ohio, the Nickel Plate, the Norfolk & Western and the American Steel Foundries. These tests were made in an effort to discover if possible just what could be expected from a spring of this design. A set of the Class *O* springs was applied to a 70-ton loaded coal car and it was found that the spring recommended as standard did not make a good showing. The Class *O* springs took an average permanent set during the test of 5/32 in. and the indications were that the springs were nearly solid under normal load. Furthermore, the rock of the car body was worse, with a single exception, than with any of the other five types of springs tested, a feature which seemed to the observers to be a serious objection. It was suggested that before the association adopts a new standard design freight car spring, it should have evidence of at least two things: first, that such a spring can be successfully manufactured, and, second, that it would prove to be a better spring than the present standard.

Mr. Kiesel, in speaking for the committee, stated that the stress



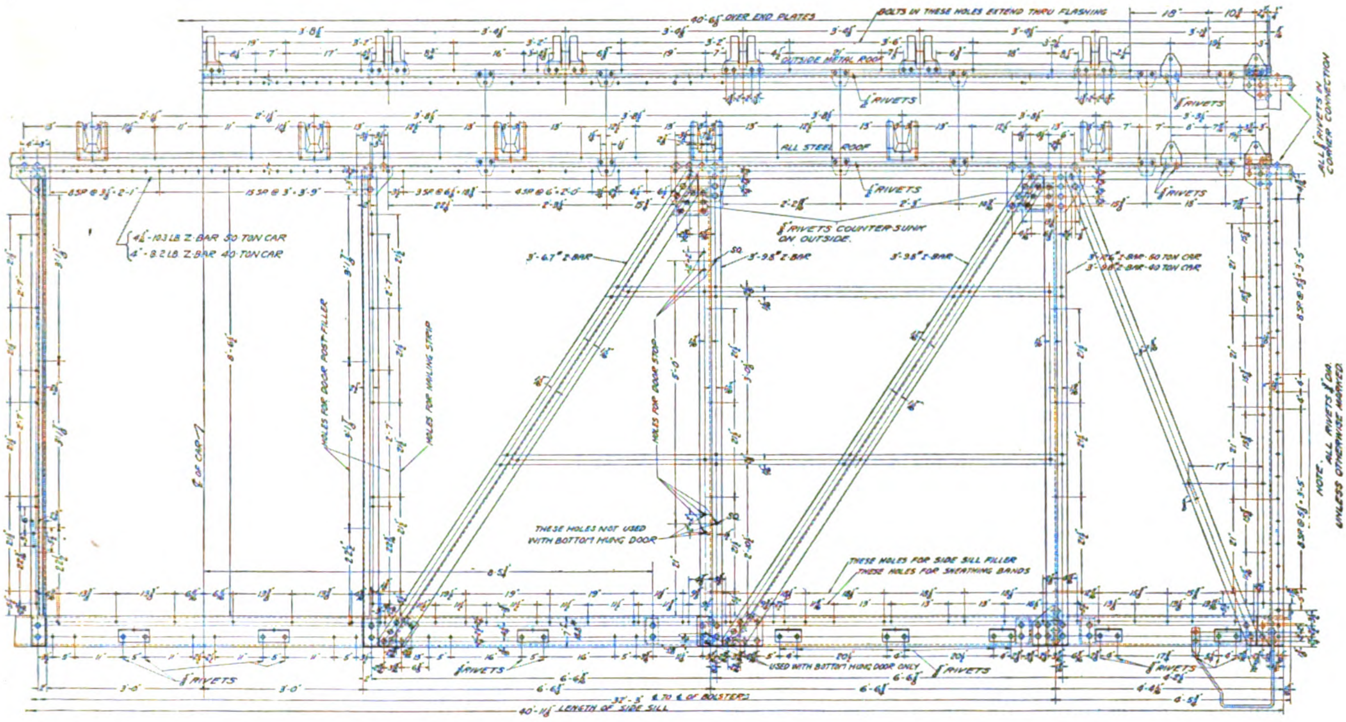
Underframe of proposed standard box cars

for the recommended spring was increased from 80,000 lb. per sq. in. to 100,000 lb. per sq. in., thereby increasing the total possible deflection about 25 per cent and the total capacity about 25 per cent. He did not consider the rocking of the car body as a satisfactory

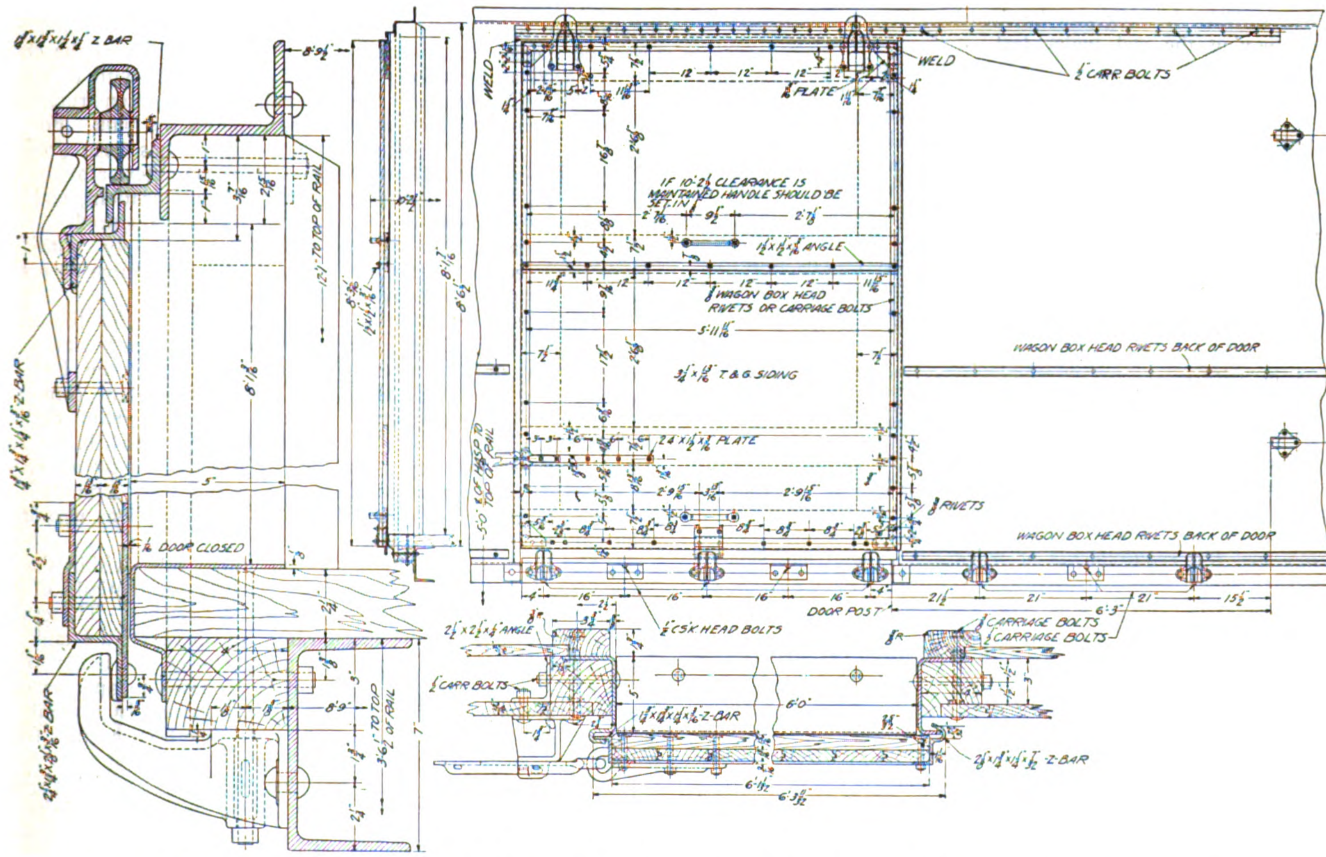
* A description of this truck will appear in a later issue.

gage of the suitability of the spring, the rocking of the car being merely an indication of the flexibility of the spring.

The question of being able to get the springs was also brought facturers cannot do what they are doing now, namely, take a bar, put it in a furnace, take it out when it is white hot and the steel is almost dripping, coil it on a mandrel, dip it in the quenching



Side framing of proposed standard double sheathed box cars



Construction of top-supported side door—Bottom-supported door can be substituted with slight changes

up. Some of the draft gears have springs in which the stress runs about 100,000 lb per sq. in. and up as high as 120,000 lb. per sq. in. Such springs will cost more because the manufacturers will have to heat them more carefully. The present method of manufacture, however, will have to be eliminated. The manu-

fluid and pull it hot and see if it smokes, and then put in the dirt and let it draw itself.

Considerable discussion was devoted to the practicability of substituting the present standard 50-ton car springs on the new standard 40-ton cars, and the possibility of amending the alloy

steel specifications so as to meet the new requirements. The object of eliminating the 50-ton car spring was to permit the use of springs of this type under a lower capacity car. It was the consensus of opinion that there is real need for a spring that will have a proper deflection under maximum loads.

Criticism was made relative to the inclusion of the drawings with a brake head, strut and brake beam in the set of drawings for the car but if that brake beam was necessary it should be referred to the Committee on Brake Equipment. It was suggested that the lug on the strut be marked as optional instead of as shown. The point was also brought out that this set of drawings might be made more beneficial if provisions were made to permit a more extensive application and the use of universally accepted alternates than the limited number now specifically covered thereon.

It was moved that on each principal drawing showing arrangements of draft attachments, striking castings, carrier irons and details, door arrangements, roofs and steel ends, a note be shown stating that any arrangement of draft attachments, striking castings, etc., may be used as an alternate if conforming to the general dimensions shown and approved A. R. A. specifications for strength requirements; that on the drawing showing the coupler release rigging a note be shown stating that any release rigging may be used as an alternate if conforming to the safety appliance laws and A. R. A. code; that in the drawing showing the side truss arrangement a note be shown stating that the Howe truss may be used as an alternate if conforming to the general dimensions shown; that on the drawings showing the trucks, notes be shown stating that trucks of proper capacity conforming to A. R. A. standard dimensions and strength requirements, may be used as alternates. The motion was seconded and carried.

Relative to the subject of box car ends, one of the committee reported that a manufacturer of steel ends had prepared drawings and is manufacturing at the present time a device for testing full size steel ends. The device is in the nature of a trip hammer and has a number of other advantages over types for the reason that it is portable and a blow can be struck at any portion of the steel ends desired or can be struck in a number of places without moving the end under test.

There were some objections to the upper limit of 20 per cent moisture in framing recommended by the Sub-Committee on Lumber for Cars. It was claimed that there is too much moisture to enter into framing members for new cars, particularly refrigerator cars. Dr. W. F. M. Goss read a communication from a committee of the Railway Car Manufacturers Association and a number of lumber producers in which was stated the difficulties involved in kiln-drying various types and sizes of lumber so as to conform to the upper limit recommended by the committee. The following recommendations relative to moisture requirements for lumber in car construction were made for the consideration of the members of the association:

Up to 1 in. thick	not to exceed 10 per cent.
Over 1 in. and up to 2 in.	not to exceed 12 per cent.
Over 2 in. and up to 3 in.	not to exceed 15 per cent.
All over 3 in.	not to exceed 20 per cent.

By action of the meeting the recommendations of the committee on the following subjects were submitted to letter ballot:

Substitution in the manual of bolsters shown in the report.

Proposed standard double sheathed box car.

Design and test requirements of truck side frames and bolsters and coupler yokes.

Hatch covers for refrigerator cars.

Axle.

Lettering and marking of cars (with suggested change in Note 2 of the drawing).

The following subjects were referred back to the committee for further investigation and report:

Tentative spring designs.

Moisture content in lumber.

Report of committee on tank cars

A number of designs of tank cars for special transportation purposes have been approved, the investigation of safety valves, dome covers and bottom outlet valves and connections has been extended and arrangements have been effected with the Interstate Commerce Commission whereunder the experimental application of appliances and appurtenances for tank car use will be made with the approval of the commission.

Approved designs of tank cars

1. ETHYL CHLORIDE CARS.—Application having been made for the approval of a car for the transportation of ethyl chloride, it was determined that, since the general requirements could be satisfied with a car having the characteristics of those covered by the Class IV specifications modified to suit the particular properties of the chemical in question, the proposed cars should be built under a sub-classification of the Class IV specifications.

These cars will have heavier plates and an expansion dome with a capacity equal to four per cent of the combined capacity of the shell and dome. This dome will have a bolted cover. There will also be an additional dome comprising a cast steel nozzle riveted onto the tank proper to which is bolted a standard Class V manhole cover and dome housing and cover.

The expansion dome is provided with two safety valves. In the filling and discharge dome two 2-in. ammonia angle valves are placed, and from one of these a suction pipe leads down into a suction bowl applied in the bottom of the tank. There is no gravity outlet mechanism.

The design is covered by specifications for Class IV-A cars appearing in the report as Appendix "A."

2. PROPANE CAR.—Designs were submitted for a Class V car for the transportation of propane, offering no departure from other cars of the same class heretofore built except that the tank is 85 in. in diameter and the car and contents are said to be heavier than the average car of similar construction now in service. The builders state that the estimated light weight of this car is 86,500 lb. and that the tank is designed for a load of 40,000 lb., or a total weight on rails of 126,500 lb.

No particular problems were presented except with respect to the braking power as to which the Committee on Brakes and Brake Equipment ruled that since the car was of a special type and the nominal braking power with the car loaded provided ample control in general service, the single cylinder 10-in. brake equipment would be accepted.

3. DINITRO-CHLORO-BENZOL CAR.—This chemical is a non-inflammable product which liquifies at low temperature and possesses no special transportation risk. The properties of the chemical are such as to make it desirable that contact with the hands be avoided. Consequently it is desirable that the construction be such as to minimize the necessity for entering the tank. For this reason a special arrangement of heater pipes has been provided to permit the withdrawal of the pipes from the exterior of the car. This car will be built under the Class III specifications, and will be stenciled "For solids only—Pressure test not required."

4. SULPHUR-DIOXIDE CARS.—These cars comply with the specification requirements for a Class V car and involve no peculiarities of design or construction.

5. ANHYDROUS AMMONIA CARS.—Requirements for the transportation of this chemical are satisfied by a Class V car. The transportation of this chemical is now limited by the I. C. C. regulations to metal cylinders, and special tank cars complying with the A. R. A. specifications and having a maximum capacity of 30,000 lb. This material loaded not to exceed 0.54 lb. for each pound of water capacity. Since there appeared to be no reason for objection to shipments in larger quantities your committee offered no objection to an amendment of the regulations permitting shipments to be made in Class V tank cars.

6. MOLASSES CAR.—The design submitted falls within the requirements for a Class III car and consists substantially of two glass-lined seamless tanks supported on steel cradles. The cradles are riveted directly to the underframe, and between the tank and the cradles 2-in. cork is provided; also between the heads of the tanks and the ends of the cradles it is proposed to apply a composition material, completely filling up the space. In general, the design follows those which have for some time been in milk transportation service.

7. NARROW GAGE CARS.—In order to satisfy special requirements for restricted service, the committee gave approval for the construction of certain narrow gage tank cars having wooden underframes required for exclusive service on the Denver & Rio Grande. Approval of the construction was with the understanding that these cars were not to be offered in interchange.

Specifications

Amendments and modifications in the specifications for tank cars are recommended as follows:

1. MATERIAL.—Specifications for Class III cars, section 2.

Paragraph (b) now reads: "Rivets shall comply with the A. R. A. specifications for Boiler Rivet Steel and Rivets for Passenger and Freight Equipment Cars." This should be revised as follows: "Rivets shall comply with the A. R. A. specifications for Rivet Steel and Rivets for Steam Boilers and Other Pressure Vessels."

Question having been raised as to whether the use of cold driven rivets was permissible, it is recommended that the following sentence be added to paragraph (b) of section 2 of the Class III and IV specifications. "All rivets shall be driven hot."

2. Tank Heads.—Specifications for Class I and II cars, section 5, paragraph 3 of this section now reads: "Tank cars formerly equipped with head blocks will not be accepted in interchange after January 1, 1926, unless tank heads have been reinforced in accordance with this section." This paragraph is inconsistent with the first and fourth paragraphs of the same section and should be omitted.

3. Dome.—Specifications for Class I and II cars, section 6. Add a new paragraph to paragraph (a) as follows: "When dome cover is renewed it shall be of cast or pressed steel or malleable iron and for screw dome cover, the depth of inside ring shall be not less than 2½ in.; and suitable vents that will be opened automatically by starting the operation of removing the dome cover shall be provided." This contemplates the omission of the note appearing under paragraph (b) for a Class II car.

4. Bottom Outlet Valve.—Specifications for Class I and II cars, section 7-c, and for Class III cars, section 7-d. Add the following to the second paragraph: "Except for cars used exclusively in the transportation of asphalt or soap products and so stenciled, a valve may be attached to the outlet if it is properly capped." Also revise the note appearing in this section of the specifications to read as follows: "In no case shall the extreme projection of bottom outlet equipment extend to within 16 in. above the top of rail, except that for existing cars having fish-belly sills the extreme projection of the bottom outlet equipment may extend to within 12 in. above the top of the rail."

5. Body Bolsters.—Specifications for Class III, IV and V cars, section 11. Add the following paragraph: "For cars built after January 1, 1926, provision shall be made for jacking under the bolsters."

6. Anchorage.—Specifications for Class II cars, section 13, paragraph (a). Add the following paragraph: "As tank cars receive repairs, wooden shims interposed between the longitudinal anchorage and the underframe shall be removed and all-metal anchorage substituted, and when the construction permits the anchorage shall be riveted to the underframe. After January 1, 1928, no cars having wooden shims interposed between the longitudinal anchorage and the underframe will be accepted in interchange."

Specifications for Class III and IV cars, section 13, paragraph (a). Add following paragraph: "For cars built after January 1, 1926, the longitudinal anchorage shall be riveted to the underframe. As cars built prior to January 1, 1926, receive repairs, when the construction permits, the anchorage shall be riveted to the underframe."

7. Safety Valves.—Specifications for Class V cars, section 20. Paragraph (d) now reads: "The design of valve and its arrangement in the dome head shall be submitted for approval." It is recommended that this be modified to read as follows: "The design of valve and its arrangement in the dome head shall be submitted for approval by the Tank Car Committee. Details of approved design will be furnished to interested parties upon application." Add a new paragraph as follows: "Valve must have discharge capacity sufficient to prevent building up of pressure in tank in excess of pressure to which tank is tested."

Repairs to tanks

One of the important users of tank cars invited the attention of the committee to the desirability of establishing certain fundamental standard maintenance practices for tank car repairs coverang particularly the thickness of plates to be applied for patches on tank shells and domes, and the method of application of such patches.

The committee has considered this subject of sufficient importance to warrant an investigation which contemplates a conference with tank car owners, and accordingly has delegated as a sub-committee J. T. St. Clair, A. E. Smith, George McCormick, Thomas Beaghen, Jr., and R. H. Owens.

Safety valves, dome covers and bottom outlet valves

The work in connection with these subjects is covered by reports of the sub-committees.

Investigations and tests designed to promote improvements in these parts for tank cars have now been in progress for several years, and while a number of appliances have been developed and applied for experimental purposes, with more or less satisfactory results, no definite conclusion as to a better and general type of dome cover, safety valve or outlet valve has yet been reached.

In view of the limited progress thus far made, your committee received approval of the General Committee of a joint investigation to be conducted by the A. R. A. Tank Car Committee, the tank car builders through the Association of Freight Car Manufacturers and the American Petroleum Institute. Negotiations with the two organizations mentioned are now in progress, and it is anticipated that a satisfactory arrangement will be reached whereby the three interests mentioned may jointly undertake the development of designs and the conduct of tests through an independent outside agency and thus not only insure an earlier decision as to the most desirable appliances for tank car application but remove the disadvantages and delays incident to the method now in effect. Your committee has delegated as a sub-committee to co-operate with the other parties at interest, your chairman, W. C. Lindner, chairman of sub-committee on Safety Valves and Dome Covers, and W. E. Cooper, chairman, sub-committee on Bottom Discharge Outlets.

It is hoped that at the next annual convention it may be possible to report definite progress in the solution of problems relating to tank car appliances and appurtenances which are so important in the safe transportation of inflammable liquids.

Service tests

Your committee has completed an arrangement whereunder service trials of appurtenances and appliances not covered by the specifications may proceed under authority of the Interstate Commerce Commission pursuant to the regulations for the "Transportation of Explosives and Other Dangerous Articles by Freight." This contemplates a limited number of applications of experimental dome covers, outlet valves and other appliances in order that developments in design and construction may be advanced and the perfection of these appliances thereby effected.

Report of sub-committee on dome covers and safety valves

Since the 1924 report four types of dome covers have been installed for test.

We believe that sufficient service trials of the A. R. A. Fundamental bolted type cover have been made and favorable reports of results obtained warrant the incorporation of the design in the specifications, and that it should be followed in all future applications to cars.

Since the 1924 report a test was made of six safety valves submitted by various manufacturers, as follows:

Identification Number.	Designer or Name.
1	A. R. A. Standard
2	Redcliffe
3	Beasley
4	American Car & Foundry Co.
5	American Car & Foundry Co.
6	American Car (Cooper)

It was the opinion of the committee that while valves No. 2, 3 and 6 did not function properly at the test, this was due to mechanical defects in the construction of the valves and not to the principles of design.

It was also the committee's opinion that the operation of the present A. R. A. standard safety valve could be greatly improved by having the springs checked up to see that they have the ends ground and are square to a center axis.

The test, therefore, developed that the present A. R. A. standard safety valve with a monel metal stem and a spider having a monel metal bushing (as represented in valve No. 5) gave the best results, and it was the consensus of opinion that a service test be made of the A. R. A. Standard valve with these features embodied, in addition to making the seat of monel metal.

By consent of E. A. Smith, J. O. Wilson, R. H. Owens and Thomas Beaghen, Jr., the American Car & Foundry Company, through R. H. Davenport, will, therefore, arrange to manufacture

24 of these valves to be applied to tank cars of the following ownership:

Union Tank Car Company	6 valves.
The Texas Company	6 valves.
Cosden & Company	6 valves.
Mexican Petroleum Corporation	6 valves.

Frequent observations are to be made of these valves in service, and at the expiration of a four-month period they are to be removed from the cars, boxed up without making any repairs or adjustments, and shipped to the Union Tank Car Company's plant at Whiting, Ind., where they will be tested out to ascertain their condition.

The committee is indebted to the Sinclair Refining Company for the use of their plant to conduct these tests, and also wishes to thank the various people and concerns who submitted valves for their co-operation in assisting the committee to carry out this work.

In connection with the 24 valves to be manufactured by the American Car & Foundry Company, and applied to cars of the Union Tank Car Company, the Texas Company, Cosden & Company and the Mexican Petroleum Corp., the committee is awaiting the development of these valves by the A. C. & F. Co. who are experimenting with various metals for the valve seats, and when completed a further test will be made at the American Car & Foundry Company's plant at Milton, Pa., before they are applied to cars for service trial, and in addition a number of other valves submitted by various manufacturers and inventors will be tested to determine if they have sufficient merit to warrant a service trial.

Report of sub-committee on bottom discharge outlets

Your sub-committee on Bottom Discharge Outlets has made a thorough study of all the correspondence and blue prints in its files and submits herewith summary showing the essential facts in regard to each design of valve so far submitted for approval for service trial. The valves indicated by an asterisk are locked on their seats, and from the standpoint of providing security against leakage caused by unseating of the valve by external violence are superior to the valves with which tank cars are now generally equipped.

Inasmuch as at present there are no definite specifications for the complete bottom discharge outlet of tank cars, it is essential that the tank car specifications be amended to definitely authorize the use of valves with which cars are now equipped and to provide for an improved type to be used on all new cars and for replacements on existing cars. Your sub-committee, therefore, submits for consideration the following suggestions:

(1) That Fig. 2 of the present A. R. A. Tank Car Specifications be revised to show a complete assembly of the bottom discharge outlet and its operating mechanism, corresponding to the illustration shown in the I. C. C. Regulations, and including all of the details of dimensions and wording shown on the present Fig. 2:

(2) That Section 7 of the Tank Car Specifications be amended as follows:

7. *Bottom Discharge Outlet.* (a) On tank cars built prior to 1926, if tank is provided with bottom discharge outlet the valve and its operating mechanism must conform in principle to the design in Fig. 2.

(b). Effective January 1, 1926, for new cars and replacements on existing cars, the bottom discharge outlet must conform to the following general requirements designed primarily to prevent accidental unseating of the valve under any condition incident to transportation:

1. A "V" groove must be cut (not cast) in the upper part of the outlet valve casting at a point immediately below the flange, to a depth that will leave the thickness of the casting at the root of the "V" not over ⅜ in. (See Fig. 2).

Exception.—In the case of steam jacketed outlets, groove may be omitted.

2. The flange on the outlet casting must be of a thickness which will prevent distortion of the valve seat or valve by any change in contour of the shell resulting from expansion of lading, or other usual causes, and which will insure that accidental breakage of the outlet casting will occur at or below the "V" groove.

3. The valve must have no wings or stem projecting below the "V" groove in the outlet casting, unless they are scored or designed to break or bend without unseating valve.

4. The valve must preferably be positively held on its seat by some mechanical means (other than a spring) providing sufficient strength to insure that the expansion of freezing liquid in the outlet casting will break off the outlet cap or the outlet casting without unseating the valve; to prevent displacement of the valve on its seat because of the movement of the car, vibration of the tank, or the effect of movement of liquid contents of the tank; and to prevent side lifting of the valve.

5. The valve and seat must be readily accessible or removable for repairs, including grinding.

6. The valve must not tighten on its seat under the vibratory action of the stem or rod.

7. The valve operating mechanism must have means for compensating for variation in the vertical diameter of the tank produced by expansion, weight of the liquid contents, or other usual causes, and should operate from the interior of the tank, but in the event the rod is carried through the dome, leakage must be prevented by packing in stuffing box and cap nut.

It is also preferable that the design of valve operating mechanism be such that the dome cover cannot be applied until the valve is closed.

8. The lower end of the bottom outlet casting must be tightly closed by means of a screw cap or a bolted cover, and to prevent leakage a suitable gasket must be used when necessary.

Before a bottom discharge outlet embodying these features may properly be applied to tank cars which may be used for the transportation of commodities defined as dangerous by the Interstate Commerce Commission regulations for the transportation of explosives and other dangerous articles, the design of the valve and its mechanism must be submitted to the Tank Car Committee for approval.

(c) To provide for the attachment of standard unloading connections—the bottom of the main portion of the outlet valve casting, or some fixed attachment thereto, shall have external "V" threads 5¼ in. in diameter, and a pitch of four threads to the inch. (Fig. 2).

Where a 6-in. bottom outlet valve is used the bottom outlet valve casting shall be designed to have a diameter of 8 in. over threads, and a pitch of four threads to the inch, in addition to connections as above (Fig. 2).

Cars used for the transportation of acids or other corrosive substances, or commodities which are not unloaded through the bottom outlet, if fitted with bottom outlet valve castings to facilitate cleaning of the car, need not have threads as above when designed for the use of a bolted cover.

(d) Same as in present specifications for Class III and IV tank cars as revised at the last meeting of the Tank Car Committee held April 17, 1925, with the words "bolted cover" properly inserted.

The report of the committee on tank cars is signed by A. G. Trumbull (chairman), chief mechanical engineer, Erie Railroad; J. T. St. Clair, engineer of car construction, Atchison, Topeka & Santa Fe; George McCormick, general superintendent motive power, Southern Pacific; W. C. Lindner, chief car inspector, Pennsylvania Railroad System; A. H. Oelkers, chief mechanical engineer, St. Louis-San Francisco; Col. B. W. Dunn, chief inspector, Bureau of Explosives; A. E. Smith, vice-president, Union Tank Car Company; T. H. Beaghen, Jr., Mexican Petroleum Company; R. H. Owens, master car builder, Mid-Continent Petroleum Company.

Discussion

It was stated that the committee expects to take up repairs to tank cars next year. Referring to tanks equipped with the head block anchorage, H. L. Shipman (A. T. & S. F.) mentioned the fact that there is no limit now set as to when a shoe patch should be applied to a tank head. It was suggested that the bottom of the head be reinforced by a shoe patch when it is caved in so that the surface of the tank is ½ in. below the original contour of the sheet. If a tank is deformed more than that, it is getting near the breaking strain at the flange and is liable to crack under a shifting load while being switched.

On motion the report was accepted and the recommendations of the committee ordered referred to letter ballot.

Report on brakes and brake equipment

In last year's report your committee gave some consideration to the question of brake beam safety supports, and have in the interim inspected a large number of cars equipped with such devices. This inspection developed the fact that a large variety of supports are being applied, but with few exceptions they require constant maintenance to maintain them in condition to serve the purpose for which they were applied. Those types which appear most dependable and free from necessity for frequent repair, in most cases, present some difficulty to the application and removal of brake beams without dismantling the truck. Your committee has not up to the present time developed anything satisfactory along the lines of an efficient brake beam safety support, but are continuing their efforts.

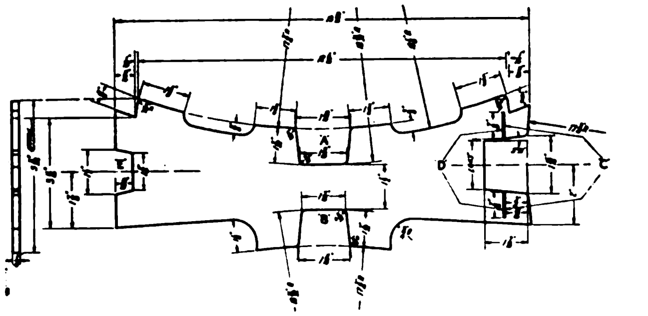
We have been requested to specify a price for brake cylinder packing other than the price now specified in Interchange Rule 101 on the basis that material of a superior quality is now available. We feel that the present price for the common brands of leather and composition packings now on the market is ample, in view of the fact that they may be procured at prices specified. We are arranging for an investigation of brake cylinder packings to determine if there is any justification for changes in Rule 101.

During 1920 your committee conducted some tests to determine if possible a standard capacity of retaining valve for freight equipment cars. Owing to the business depression following this work was not concluded. The committee has been

instructed to resume investigation of this subject and have made some preliminary tests.

During the past year your committee has completed the revision of Rules and Regulations for Testing, Inspection and Maintenance of Power Brakes. In this connection we would call attention to rule 15 (a) and (b) in the Passenger Code of Interchange Rules. This rule should be modified as follows:

Rule 15 (a) Brakes must be in perfect working order. Brake cylinders, slack adjusters, triple valves, control valves and high speed reducing valves must have been cleaned, oiled and tested within twelve months, and date



Brake shoe gage

of last cleaning and oiling stenciled with white paint in a suitable location for visual inspection. Dirt collectors and strainers must be cleaned at time of cleaning triple valves or control valves.

(b) Piston travel less than 7 in. or more than 9 in. with maximum service brake application, must be adjusted to nominally 8 in.

Classification of Rebuilt Brake Beams in order that second hand beams might be classed and charged for at the same price of new beams has been considered, however, you will appreciate that repaired beams are placed in exactly the same service as new beams, and may be expected to become subject to necessity for further repair in much less time than the latter; and the charges and credits for repaired beams we think, are ample to reimburse the railroads for such repairs. We are under the impression it would be a mistake to establish for repaired beams the same status as applies to new beams.

Brakes and brake equipment

In connection with brake beam safety supports your committee has considered brake beam troubles due to failure of hangers. The present A. R. A. brake head provides for a 1-in. brake hanger, and recently the drawings were modified to eliminate the sharp edges in the hanger groove to prevent wearing hangers, causing them to break in the corners. The committee will co-operate through a sub-committee with the Arbitration Committee who now have this subject under consideration, with a view of providing details for brake beam and brake hanger maintenance.

Suggestions for changes in graduating springs for freight triple valves has been made and we wish to advise that this matter is now in the hands of the Director of Research A. R. A. who contemplates tests of such devices. Suitable action will be taken in accordance with the information disclosed by such tests.

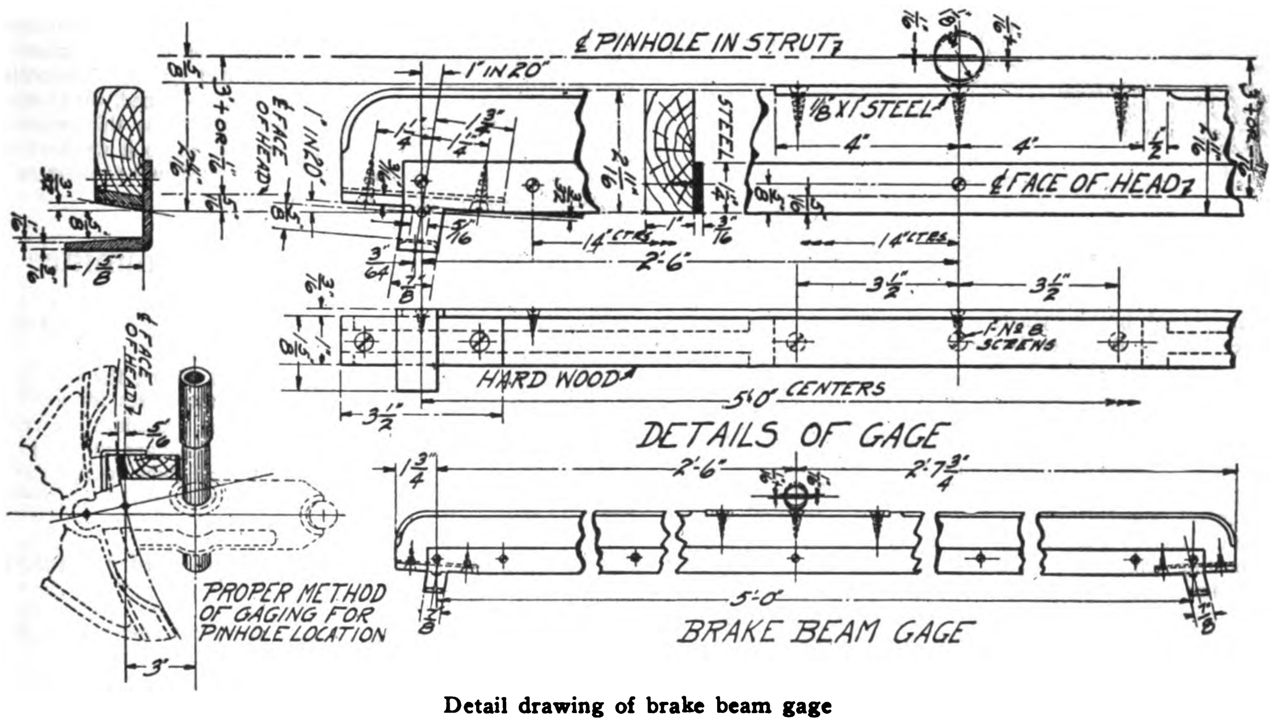
Recommendations

The 1921 report of the committee on Brake Shoe and Brake Beam Equipment contained a drawing of the A. R. A. brake beam gage, which showed several changes over the gage adopted in 1920 and which is still the A. R. A. standard. The present standard adapted itself to beams made to hang 14 11/16-in. on a 33-in. wheel when the strut was parallel to top of rail, however, the position of the present standard A. R. A. brake beam is 13 in. from center of brake head to top of rail and it will be necessary to change the dimension 2 15/32 in. from front to back of gage to 2 11/16 in., and provide a taper of 3/32 in. to that part of the gage which comes in contact with the face of the upper head lug. These changes were outlined in the 1921 report. We would, therefore, at this time recommend the changes in brake beam gage drawing shown in the A. R. A. Manual, division (B), page 7, to conform to that shown in the accompanying drawing.

We would also recommend changing the present A. R. A. brake head gage drawing shown on page 8, A. R. A. Manual, division (B), to conform to that shown below, as this gage is universally used by brake beam manufacturers because it has the advantage of more accurately gaging the entire face of the brake head, and there are no changes of dimensions which will affect the present A. R. A. standard.

An apparent weakness in the present A. R. A. brake shoe gage has been brought to our attention and we would recommend a change in the present drawing shown on page 9, A. R. A. Manual, division (B), in order to increase the dimension ¾ in. to 1½ in. and strengthen the gage at the center as shown in the drawing.

Attention has been directed to the practice of stretching springs in the spring type retaining valve, presumably for the purpose of overcoming leakage of valve seats. This trouble was more prolific when the spring type retainer first came into general use than is the case at the present time. The committee

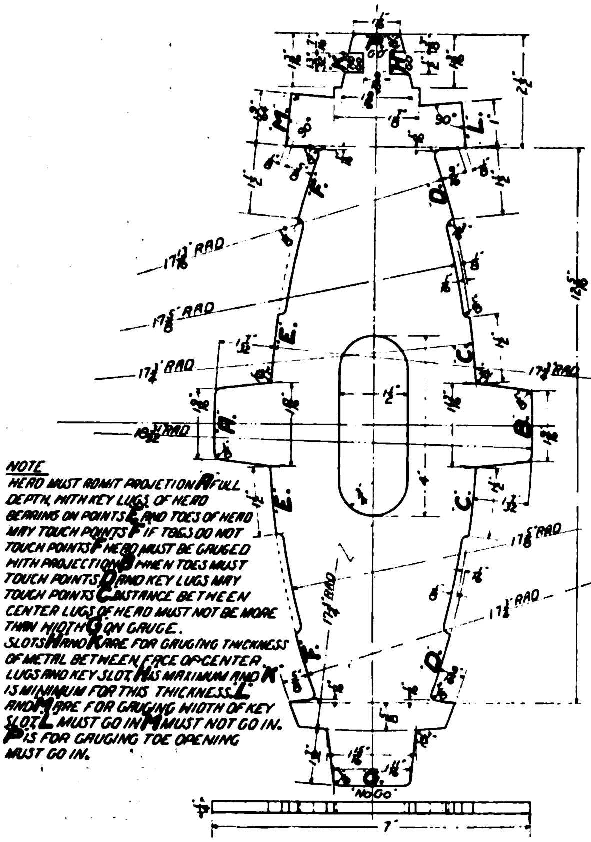


Detail drawing of brake beam gage

recommends that each road call attention of their repair men to the practice of stretching these springs and request that such practice be discontinued. Stretching the springs increases the brake cylinder pressure retained, reduces the flexibility of control and may contribute to wheel and brake shoes troubles.

Your committee recommends for letter ballot the following:

The committee's attention has been called to cases where there is an appreciable difference in the actual and nominal diameter of brake cylinders which influences the life and efficiency of brake cylinder packing on account of cylinders being considerably larger than the nominal diameter. Your committee would, therefore, recommend for adoption as recommended practice, that the



Brake head gage

actual diameter of brake cylinders for freight cars should not exceed the nominal diameter by more than 1/16 inch.

Advancing to standard the present recommended practice brake beam having central head hanging only.

This report is signed by G. H. Wood (chairman), supervisor of air brakes, Atchison, Topeka & Santa Fe; T. L. Burton, air brake engineer, New York Central; B. P. Flory, superintendent motive power, New York, Ontario & Western; J. M. Henry, general superintendent motive power, eastern region, Pennsylvania System; W. H. Clegg, chief inspector air brakes and car heating equipment, Canadian National Railways; Mark Purcell, general air brake inspector, Northern Pacific; R. B. Rasbridge, superintendent car department, Reading Company; G. E. Terwilliger, supervisor of auxiliary equipment, New York, New Haven & Hartford.

Discussion

In obtaining data for this report, it was stated that the committee inspected a large number of cars equipped with different types of brake beam safety supports and found them in all stages of disrepair. The support would be missing entirely on one truck or on one side of one truck; in some cases they were missing on both trucks. The opinion was expressed that supports riveted rigidly to the truck frame cannot be depended on and that they require too frequent maintenance to be kept in condition and the inspectors are not giving them sufficient attention.

It seemed to be the consensus of opinion that something should be done to improve the general air brake cylinder packing situation. While there are packings on the market which give much better performance than the packing provided for at the price given in the rules, the point was made that the average railroad cannot be justified in putting the higher price packing into foreign cars and getting other packing back in its own cars. It was stated that the New York Central has been operating a number of types of packings out of New York City and Chicago for practically four years. These packings are inspected periodically with a gage to determine leakage and as a result of these tests this road has been materially relieved of troubles from brake cylinder leakage.

One speaker in commenting as to the relative merits of the Wabco packing leather as compared with the leather which was formerly used for the retaining ring stated that his road had purchased a great many more of the Wabco cups for renewal than it had in previous years. However, an investigation showed that a large number of the Wabco cups had been scrapped when they were in perfectly good condition.

Attention was called to the fact that considerable difficulty is apt to be incurred in the application of the composition cup. The cup is not compressible like the other cup and unless the men handling it are cautioned, they are likely to put on the follower and tighten the nuts the same as before, with the result that the man testing out the brake gets a blow past the sleeve. He thinks it is a leaky cup and takes it off.

The opinion was expressed that rust is one of the important sources of packing cup wear. There is no question about the fact that rubber has abrasive qualities that are not present in leather. When the Wabco cup was first brought out, it seemed to be the consensus of opinion that anything in the way of grease or oil could be used to lubricate the cylinder. It was found by actual test that it was necessary to have a high grade cylinder lubricant, otherwise the cylinders would rust and cut out the cups.

The committee is seeking information as to the experience on different roads with various types of composition packing in order that it can make such recommendations as will enable the railroad to put a freight car in service and run it from one cleaning period to the other.

In discussing the subject of stencilling uncleaned triple valves, Chairman Tatum remarked that during the past year he had had brought to his attention triple valves on cars stencilled as clean, but on which the triple valves had not been cleaned. There were also instances where he had seen the dirt collectors stencilled as having been cleaned when they were not cleaned. He suggested that a rule should be framed which will cause this work to be done right or that will make it expensive to do it wrong.

The report of the committee was accepted and recommendations made therein referred to letter ballot.

Report of arbitration committee

During the year Cases 1,333 and 1,383, inclusive, have been decided and copies sent to the members. A vote of concurrence in the decisions is requested by the committee.

Considerable variance has been noticed during the past year as to the course of the procedure in submitting cases for arbitration. The fundamental principles governing this procedure are re-stated in the report. All recommendations for changes in the rules of interchange submitted by members, railroad clubs, private car owners, etc., have been considered and, where approved, changes have been recommended.

Recommended changes in the rules of interchange

RULE 2

The committee recommends that the second paragraph of Section (b) be modified as follows:

For inside door protectors, *side or end*, the car transfer check, etc.

RULE 3

The committee makes the following recommendations; that the effective date of the second paragraph of Section (b) be extended to January 1, 1927; that the effective date of the second paragraph of Section (d) be extended to January 1, 1928; that the effective date of the next to last paragraph of Section (e) be extended to January 1, 1927.

The committee recommends that the effective date of Section (i) be extended to January 1, 1927, and that the section be modified as follows:

Cars built new on or after January 1, 1927, will not be accepted

from owner unless equipped with steel underframe having a minimum cross sectional area of 24 square inches between the draft back stops.

Cars built prior to January 1, 1927, will not be accepted from owner on or after January 1, 1928, unless equipped either with steel underframe, wood or metal draft arms extending beyond the body bolster, or metal draft arms extending to metal body bolster and securely riveted to same.

The committee recommends that the effective date of the second sentence of Section (1) be extended to January 1, 1927.

Rule 4

The committee recommends that the second paragraph of this rule be changed as follows:

Defect cards shall not be required for any slight damage (new or old), that of itself does not require repairs before reloading of car, except that the car may be used, under load, in movement to shop for the required repairs.

The recommended modification is a reasonable exception to the general rule which contemplates that cars with defects requiring repairs shall not be continued in service indefinitely. The general restriction against reloading defective cars is advisable as a measure against the issuance of defect cards for unnecessary repairs.

With reference to the second sentence of the present rule, the experience has been that in many cases it is practically impossible to determine whether the defects were new or old.

Rule 9

The committee recommends that make or name should be omitted from the information to be specified on billing repair cards after item of brake beams, R & R.

Rule 17

The committee recommends that Section (e) of this rule be modified as follows:

A. R. A. No. 2 or A. R. A. No. 2 plus brake beams may be used in repairs to all freight equipment cars equipped with non-A. R. A., A. R. A. No. 1, or A. R. A. No. 2 brake beams; charges and credits to be on basis of beams applied and removed. A. R. A. No. 2 plus and A. R. A. No. 3 brake beams must be replaced in kind.

Rule 30

The committee recommends that Section (g) of this rule be modified as follows:

When a car is reweighed and remarked the car owner must be promptly notified of the old and the new weights, with place and date. The proper officer to whom these reports should be made will be designated in The Official Railway Equipment Register.

Rule 32

The committee recommends the addition of a new second paragraph to this rule to read as follows:

Steel tank heads (on tank cars), burst, except when due to inferior material, material less than required thickness, omission of reinforcing shoes where required, burned in flanging, welds or other improper workmanship; in any of such cases handling line must furnish car owner with statement showing actual condition of tank head which caused the failure.

The committee recommends that Item 4 of Section (d) of this rule be changed as follows:

No rider protection when necessary, if car is damaged to the extent shown in Rule 44. The same responsibility applies also, if car is damaged to the same extent (per Rule 44), due to defective, ineffective or inoperative hand-brake rigging, while handling car with rider protection, even though such faulty conditions may have developed during the switching operation.

The elimination of Item 4 from Section (d), and the substitution of combination factors on certain classes of tank cars to constitute handling line responsibility, as proposed by the American Petroleum Institute, is not concurred in.

The claim for this additional protection is based on the premise that tank cars comply with the tank car specifications of the American Railway Association, in some instances exceeding them, and that therefore, any damage to the sills must of necessity be the result of improper handling.

The fact that tank cars when built meet the A. R. A. tank car specifications does not of itself guarantee against subsequent failures of sills, etc., in fair service, resulting from deterioration or accumulation of strain and fatigue. Failure of buffer castings is of frequent occurrence in fair service, resulting largely from defective or inadequately maintained draft gears and coupler back stops. In this same connection, the coupler is also subject to failure although conforming to the Specifications.

The committee recognizes that under the present Rule 32 owners are obliged to assume responsibility for extensive damage to cars, some of which may have been due to improper handling, particularly by excessive impact, and, therefore, with the view of placing upon handling lines a greater measure of responsibility for the careful handling of equipment and, further, to encourage a higher standard of hand brake maintenance, the above changes are justifiable.

The committee recommends that Item 5 of Section (d) of this rule be modified as follows:

Coupling on with locomotive when first car is damaged, including damage to adjoining cars (in consecutive order) in same draft.

The committee recommends the elimination of the last paragraph of this rule as it has been covered by the second paragraph of Rule 4.

Rule 33

The committee recommends that the first paragraph of this rule be modified as follows:

Owners will be responsible for the expense of repairs to safety appliances where not involved with other delivering line damage, except on tank cars when sideswiped or cornered.

Rule 43

The committee recommends that the note under this rule be eliminated as it is covered in the new Rule 44.

The committee also recommends that the Interpretation No. 2 of this rule be eliminated on account of the new second paragraph of Rule 32.

New Rule 44

The committee recommends a new rule, to read as follows:

When a car is damaged to the extent shown below, if it occurred in ordinary handling, a statement must be furnished showing the circumstances under which the damage occurred in order to establish the responsibility of the car owner for the repairs. This statement, in the case of cars reported under Rule 120, to accompany request for disposition of car, and, in cases where it is not necessary to report the car under Rule 120, to accompany the bill for repairs.

(1) Six or more longitudinal sills on wooden underframe cars; however, if not more than three sills are broken new, the renewal or splicing of the remainder being necessary account of decay, elongated bolt holes or other old defects, a statement as to the existence of such old defects will be sufficient evidence of the responsibility of car owner for all repairs, providing after a thorough investigation it was not found that car was subjected to unfair handling as provided by Rule 32.

(2) Five or more longitudinal sills on composite wooden and steel underframe cars.

(3) Four or more steel longitudinal sills on steel or steel underframe cars.

(4) All longitudinal sills on all-steel underframe cars having but one steel center member.

(5) Two steel center members on tank cars having two steel longitudinal sills only.

(6) Steel tanks of tank cars shifted where secured by bolster or center anchorage.

(7) Saddle sheared from tank, or tank sheet buckled between saddle castings, or damage to both draft members on same end of car, on tank cars without center sills.

Note: Draft members, wood or steel, extending from end sill to end sill and used to reinforce center sills, are not longitudinal sills.

Reason: In view of the recognized weakness of many of the wooden underframe cars due to decay or other old defects in the sills, which are unquestionably owners' defects, and the impossibility of determining the actual circumstances under which the final failure occurs in such cases, the handling line is entitled to a greater measure of protection than is afforded under the present rule. The insertion of the note with reference to continuous draft members is considered necessary for a uniform understanding.

Rule 60

In order to prohibit the cleaning of air brakes until after the expiration of eleven months, unless car is shopped for other repairs or the air brakes are defective, the committee recommends that the second paragraph of this rule be changed as follows:

After the expiration of nine months, if car is on repair track for other repairs, the air brakes may be cleaned at same time. After the expiration of eleven months, the air brakes may be cleaned irrespective of whether car requires other repairs.

RULE 76

The committee recommends that this rule be changed as follows:

Tread worn hollow—cast iron and cast steel wheels: if the tread is worn so that projection on under side of gage does not come in contact with tread of wheel. (See Fig. 4-D), or rim liable to breakage.

Tread worn hollow—wrought steel wheels: if height of flange is 1½ inches or over, as measured with standard steel wheel gage or approved equivalent.

Note: The drawing of the standard wheel gage will be shown in the 1925 report of the Committee on Wheels.

RULE 86

The committee recommends that the wheel seat dimension for the 70,000-lb. capacity axle, shown in the table under Section (a) of this rule, be changed from 5⅝ in. to 5¾ in., as recommended by the Committee on Car Construction.

The committee recommends that standard Class "F" axles be added to the table under this rule as follows:

A Total weight on rail	B Nominal capacity	Limits of Wear					Dimensions, New						
		C	D	E	F	H	C	D	E	F	G		H
Lb.	Lb.	In.	In.	In.	In.	In.	In.	In.	In.	In.	Ft.	In.	In.
251,000	200,000	6	7⅞	6¾	12½	¼	6½	8⅛	6⅞	12	7	8¾	⅞

The committee recommends that the second, third and fourth paragraphs of Section (b) of this rule be changed as follows:

A. R. A. Standard axle shall be used to replace non-A. R. A. Standard axles of like capacity when over-all length conforms to A. R. A. Standard, and shall also be used to replace A. R. A. Standard 60,000 lb. capacity axles having wheel seat less than condemning limit for such axle, at expense of car owner, except that in case of delivering line defects the charge against owner shall be confined to the difference in value between the non-A. R. A. Standard axle or A. R. A. Standard axle removed and the A. R. A. Standard axle applied.

Non-A. R. A. Standard axles may be used to replace non-A. R. A. Standard axles in kind, until January 1, 1928, only in such cases where A. R. A. Standard axles are not a proper substitute.

The fourth paragraph is eliminated.

RULE 91

The committee recommends that the last sentence of Section (c) of this rule be omitted, a new paragraph be added as Section (d), and that present Sections (d) and (e) become new Sections (e) and (f) respectively, as follows:

(d) If objections to bill, as per Sections (b) and (c), do not amount to $1.00 in aggregate no exception shall be taken, but bill shall be passed for payment as rendered. In any case, however, if entire bill is improperly rendered, it may be returned regardless of its amount.

RULE 98

To simplify billing transactions, the committee recommends the addition of a new paragraph to Section (g) of this rule, as follows:

The amount of service metal on both wheels will be governed by the minimum amount on either wheel, except when a defective wheel is necessarily scrapped before it reaches the limit of wear, in which case the service metal on mate wheel will be credited on basis of the actual amount.

RULE 101

The committee recommends that Items 127 and 128 of this rule be eliminated and that Items 132 and 133 be modified as follows:

Item 132: Coupler body, A. R. A., one, new, or second-hand, steel, 5 in. by 7 in. shank .... charge $9.41, credit $1.10.

Item 133: Coupler body, A. R. A., temporary standard, one new or second-hand, steel, 5 in. by 7 in. shank .... charge $10.35, credit $1.23.

RULE 104

The committee recommends that first two paragraphs of this rule be modified as follows:

Second-hand A. R. A. couplers or parts shall be charged and credited at 75 per cent of value new, except that new or second-hand coupler body, steel, 5 in. by 7 in. shank, former standard or temporary standard, shall be charged and credited at prices specified in Items 132 and 133 of Rule 101. Credits shall be confined to the body, lock, knuckle and knuckle pin, whether second-hand or scrap. In the Type D coupler, credit shall be allowed for all parts.

When new A. R. A. coupler is applied it shall be so charged whether or not it is of same make as that removed, except that where new coupler body, steel, 5 in. by 7 in. shank, former A. R. A. standard or temporary standard, is applied it shall be charged at value shown in Items 132 and 133 of Rule 101.

Passenger car rules of interchange

RULE 2

The committee recommends that the first paragraph of this rule be modified as follows:

Cars, loaded or empty, offered in interchange with defects for which owner is responsible, provided they are equipped with air brake, air signal and steam heat train line having end steam valves and otherwise meet the requirements of the receiving line as to safety and clearances, must be accepted, with the following exceptions:

RULE 7

The committee recommends that Item 4 of Section (f) of this rule be revised to conform to the recommended revision of freight car Rule 76.

RULE 8

The committee recommends that Section (c) of this rule be modified as follows:

Cast-iron wheels in place of cast-steel, wrought-steel or steel-tired wheels; cast-steel wheels in place of wrought-steel or steel-tired wheels; steel-tired wheels in place of wrought-steel wheels.

The members of the committee are T. W. Demarest (chairman), Penna.; F. W. Brazier, N. Y. C.; J. Coleman, Canadian National; W. H. Fetner, M. P.; J. J. Hennessey, C. M. & St. P.; J. E. O'Brien, Seaboard Air Line; H. L. Shipman, A. T. & S. F., and G. F. Laughlin, Armour Car Lines.

Discussion

The discussion of this report was very brief as it dealt only with the withdrawal of two recommendations made by the committee. It was decided to withdraw the recommendation for the change in Rule 17 and with reference to Rule 32, Item 4, Section (d), the committee decided to cross out the word "ineffective" because of the possibility that the word may be misconstrued.

The report was accepted as presented.

Prices for labor and materials

The committee submitted the following report under A. R. A. Interchange Rules 101, 107, 111 and 112 and the freight car code Rule 22.

Prices for materials—Rule 101

New prices are provided for reinforced doors on automobile and refrigerator cars. Items 125 and 128 are eliminated and items 132 and 133 changed at the suggestion of the Arbitration Committee.

To discourage the practice of cars being held out of service awaiting receipt of friction gears from the owners, and to facilitate the preparation and checking of bills, the committee has recommended a proposed addition to Rule 101. The new prices proposed are to be charged for various friction draft gears applied new complete, when necessary to apply complete gear on account of any or all parts of old gear becoming defective. In conformity with Rule 88, one type of gear may be substituted for another if the type substituted conforms to the one removed as to sill spacing and coupler pocket limits. In such substitution complete gears removed shall be credited at 25 per cent of the price new, complete, when removed on account of defective friction casing or castings, and at 50 per cent of the price new, complete, when removed on account of any other part or parts of the gear being defective.

Second-hand complete friction draft gears shall be charged at 75 per cent of the price new, complete.

When new or second-hand parts of any type of friction draft gear are applied in replacement of such parts becoming defective, they should be charged at the factory prices, as new, plus 15 per cent.

New Item: 16-a—Arch bar, on trucks without column bolts and

with channels riveted to arch bars, one or all on same side, R & R or R, charge on bolt and rivet basis. Add jacking of car when necessary.

New Item: 19-a—Cylinder body, combined type (body only), charge for 8-in. $5.47, and for 10-in. $6.60.

New Item: 19-b—Cylinder, complete, detachable type (without push rod), Nos. 69817-69751, charge for 8-in. $12.32 and for 10-in. $16.80.

New Item: 19-c—Cylinder complete, combined type (without push rod), Nos. 69816-69818, charge for 8-in. $11.07 and for 10-in. $15.55.

New Item: 108-a—Brake connection, bottom, forged, hollow design, price of each $2.40; credit $0.12.

New Item: 142-a—Coupler cross key lock, U type, price for each unit $.055; credit $.005.

New Item: 156-a—Half door or twin door, reinforced type, for the side of an automobile car, price for each applied $19.00. No credit for scrap.

New Item: 156-b—Half door or twin door, right hand with fixtures, for the side of refrigerator cars, wooden, price of each applied $24.45. No credit for scrap.

New Item: 156-c—Half or twin door, left hand, for the left side of refrigerator cars, wooden, price of each applied $17.38. No credit for scrap.

Prices of labor—Rule 107 and 111

Investigations reveal that no change is warranted at this time in existing labor allowances per hour as set forth in Items 427, 442 and 443.

The report recommends several changes in the wording of items in Rule 107 to define more clearly what is included in the time allowances, some of which are changed, and the following new items are added:

New Item: 121-a—Coupler cross key lock, U type, R & R or R, when coupler cross key is not R & R or R. Ordinary refrigerator cars—3 hr.

New Item: 317-a—One end sill, flush type, on open top cars, renewed, includes R & R or R of end stakes outside of car. (No extra charge for coupler R & R or R at the same time.) Ordinary car—9 hr.

New Item: 319-a—One end sill, flush type, on open top cars, renewed when one or more defective sills are renewed or spliced, includes R & R of end stakes outside of car. Ordinary car—7 hr.

Destroyed or damaged cars—Rule 112

The committee recommends a complete revision of Rule 112 in line with the slight reductions occurring in the market prices.

The following addition has been proposed to be added to this rule: A refrigerator car is either an RA, RB, RM or RS car as defined in Section L of the A. R. A. Manual. All VS, VA, Eastman Heater and other special types of house cars should be settled for on a box car basis.

It is proposed to change, in Interchange Rule 22, the price of Pintsch gas per receiver set from $1.54 to $1.60.

The report is signed by A. C. Calkins (chairman), N. Y. C.; Ira Everett, Lehigh Valley; J. K. Watson, A. T. & S. F.; T. J. Boring, Penn.; H. H. Harvey, C. B. & Q.; H. H Boyd, Canadian Pacific; A. E. Smith, Union Tank Car Company, and M. R. Esherwood, Swift & Company.

Discussion

After the reading of the report Mr. Calkins stated that Items 179 and 187 contained allowance for refrigerator cars which should come out.

The report was adopted as presented by the committee.

Report on couplers and draft gears

In order that the subject of draft gears might be exhaustively studied, the committee recommended, under date of December 6, 1924, that the sum of $50,000 be appropriated to cover the cost of designing, building and housing a 27,000 lb. drop test machine together with the necessary recording apparatus.

This recommendation was unanimously approved by the General Committee, and the Board of Directors on March 20, 1925, authorized an appropriation of $50,000 for constructing a drop test machine as recommended. The necessary steps are being taken in arranging for the detail plans and building of this machine, determining upon the most suitable location for its installation, and erecting it, all of which under the direction of the Mechanical Division and with the supervision of the president of the Association will be brought to as speedy a conclusion as possible.

The information that will be developed by this testing machine will be of the greatest value to the railroads as strictly comparable data on the performance of draft gears of different designs, both new and after periods of wear in actual service, will be available.

From the information to be obtained, suitable specifications are to be prepared for the purpose of eventually restricting the use of draft gears to those that are known to meet the prescribed standards of efficiency and through the experiments to be conducted obtain such facts and information as will assist in the development of draft gears generally.

Couplers other than A. R. A. standard

The present specifications for purchase and acceptance of A. R. A. Standard "D" couplers, knuckles, locks and other parts make no reference to couplers of former types which are being ordered for repairs and will be required until the disappearance of cars of design not suitable for the Standard "D" coupler.

It is felt that the static and dynamic tests formerly required for M. C. B. couplers should be dispensed with and that for such types the tests need cover the quality of the material only.

To meet this situation the note now appearing under the title of the present specifications for Standard "D" couplers should be revised to read as follows:

"These specifications replace specifications for M. C. B. automatic couplers adopted in 1899. When couplers other than type 'D' are ordered under these specifications, they shall conform to the requirements for quality of steel, workmanship, and details of inspection. No tests of the couplers as a whole will be required."

It is recommended that the reissuance of this note be referred to letter ballot.

Failure of cotters securing draft gears

Attention is directed to the frequent failure of the various forms of cotters in general use for securing cross draft keys in place. These cotters are failing both on account of being worn away due to contact with the draft castings. and from being sheared off due to lateral movement of the coupler and draft key when curving.

The washers encircling the cross draft key used by some roads greatly improve the conditions resulting from wear but are of no benefit as concerns shear.

An investigation conducted by your committee shows that while the failure of these cotters is most frequent in the front cross draft key it occurs to a considerable extent in all keys. Cases have been observed of U-shaped cotters made of ⅝ in. steel being sheared off on new cars when being moved over curves.

It is proposed to cover this matter in a circular to the members as soon as it has been determined which of certain methods under consideration for correcting the trouble are most satisfactory.

Standard "D" couplers—Minor changes

In order to determine how the Standard "D" couplers and parts are standing up in service and whether any changes in the detail design should be made, the roads represented on your committee have arranged for special examination and report on each Standard "D" coupler or part requiring renewal during a period of six months.

These reports will be consolidated to show just what is taking place and should indicate clearly whether the present coupler is equal to the service conditions encountered, and whether any modifications in design should be made. The results of this investigation will be included in our report to next year's Convention.

Your committee has authorized a few changes of a minor nature in the detail designs of the standard "D" coupler and gages, none of them in any way affecting interchangeability or strength of the parts, and all of them being agreed to by your committee and the mechanical committee of the coupler manufacturers and the standard drawings on file corrected accordingly.

The report was signed by R. L. Kleine (chairman), assistant

chief of motive power, Penna.; J. R. Onderdonk, engineer of tests, B. & O.; C. J. Scudder, superintendent motive power and equipment, D. L. & W.; J. A. Pilcher, mechanical engineer, N. & W.; C. B. Young, general mechanical engineer, C. B. & Q.; Samuel Lynn, master car builder, P. & L. E.; L. P. Michael, mechanical engineer, C. & N. W.; E. A. Gilbert, general master car repairer, S. P.; and Prof. L. E. Endsley, University of Pittsburgh.

Discussion

It was pointed out during the discussion that definite plans were under way for the installation, at some accessible university, of a draft gear drop test machine. The appropriation of $50,000 for this machine was mentioned in the General Committee's report.

It is considered a waste of time to make drop tests at the manufacturers' plants on couplers of the standard design. The drop and jerk tests were design tests to protect the railroads when buying couplers of an unknown quantity. However, the railroads should be assured that the steel used in the couplers is of a proper quality.

The report was accepted and referred to letter ballot.

Report of loading rules committee

During the past year the committee has been in conference with the automobile shippers and the steel industries on the subject of Loading Rules as applied to their products. These shippers, as well as others, have placed before the committee a number of recommendations for changes and additions to the Rules. Trial shipments involving new methods of loading small diameter tanks, concrete pipe and wide plates not adequately covered by the Rules were followed through to destination in order to determine whether they were practical and safe.

As a result of its investigations the committee submits the following changes and additions to the Rules for approval and submission to letter ballot for adoption as standard of the Association.

Changes in general rules for the loading of materials on open top cars

Rule 13, First Paragraph—The width of overhanging loads placed on single cars, *when flat cars are used as idlers,*

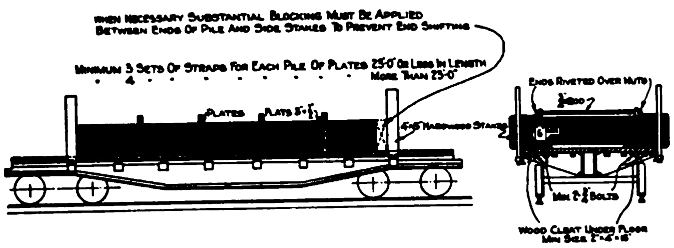


Fig. 44E—Manner of securing wide plates loaded on flat cars

must never exceed the following dimensions as a maximum and the load must be governed by the total length of lading and weight limits prescribed in table under Rule 23 for the length of car used. *When gondola cars are used as idlers see limitations prescribed in Rule* 221.

Rule 28—Bearing-pieces must never be placed between bolster and end of car, unless special provision (*See Rule* 217) is made therefor in detail instructions. (The remainder of the paragraph is unchanged).

Changes in rules governing the loading of lumber, logs, ties, etc.

Rule 100—The following is added to Section B:

Height of load given is measured either from floor line of flat cars or from top of sides of gondola cars.

Section C. For loads of lumber or timber, not of equal thickness which cannot be lapped or stripped, the sizes of hardwood stakes must not be less than 4 *in. by* 4 *in.*

EXPLANATION: Sections B and C are revised to conform with the second paragraph of Rule 102.

Changes in rules governing the loading of structural material, plates, etc.

Proposed New Rule 201-A—When plates are too wide to be loaded in accordance with Rule 201 they may be loaded in accordance with Fig. 44-E. When so loaded there must be at least three tie straps, each not less than ½ in. by 3 in, to each pile of plates 23 ft. or less in length and four tie straps, each not less than ½ in. by 3 in. for each pile of plates over 23 ft. in length.

Each tie strap must be secured by not less than two ¾-in. bolts spaced at least 6 in. apart and passing through floor of car with cleats under floor 2 in. by 4 in. by 18 in. The material

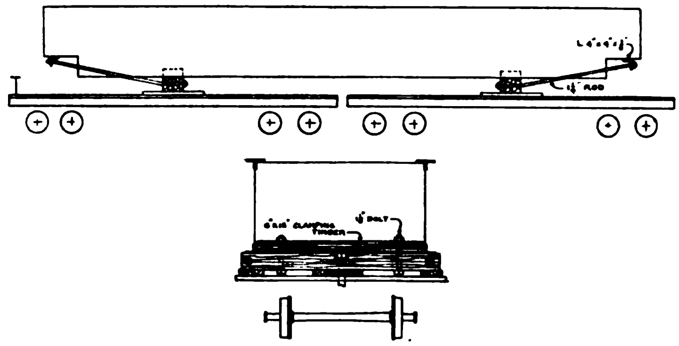

Fig. 76A—Loading of turntables

must be placed against stakes not less than 4 in. by 5 in. at one end of the car and at the opposite end two stakes not less than 4 in. by 5 in. must be placed in the nearest stake pockets to the end of the load. If there is any space between the end of the load and stakes, this space must be built up as per Fig. 44-E to prevent end shifting. Care must be taken to have the straps fit the load snugly and the tops of the clamps must be tied together by ¾-in. rods with ends riveted over nuts.

EXPLANATION: Numerous shipments have shown this method clamping to be satisfactory and it takes care of wider plates than now provided for in the rules.

Rule 203—Gondola cars loaded with plates or other material on floor of car may have plates that are too wide for the car loaded on top of car sides when height of sides does not exceed 3 ft. (See Fig. 45 or 45-A). Such superimposed plates must be supported by posts 4 in. by 6 in., one set of posts for each 6 ft. length of lading, with a minimum of three sets of posts for each tier of plates. Side motion to be prevented by not

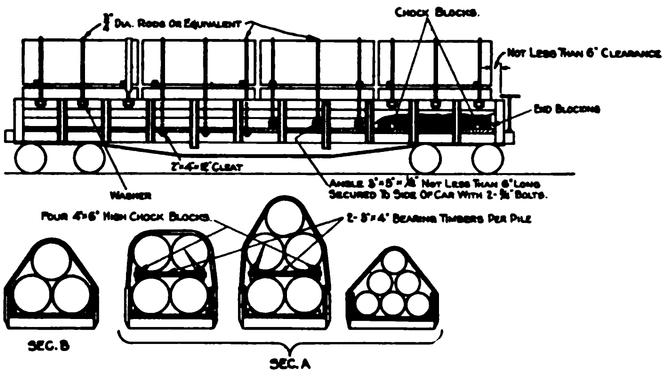

Fig. 101A—Manner of loading small diameter tanks on flat and gondola cars

less than three clamps constructed as shown in Figs. 45 or 45-A. Longitudinal motion to be prevented by *uprights*, 4 *in. by* 6 *in. bolted to side of car with ⅞-in. bolts and backed up by struts* 2 *in. by* 8 *in. spiked or bolted to sides of car.* Total weight of plates loaded in this manner must not exceed 75 per cent of the Load Weight, as per General Rule 5.

EXPLANATION: Rule revised to prevent end shifting of the plates. It was found by experience that the diagonal struts split readily when placed directly against the plates.

Rule 211—When one or both bearing-pieces are placed on the car floor they must be located over the car body-bolster or between car body-bolsters, and must never be placed between car body-bolster and end of car unless special provision (*See Rule* 217) is made therefor in detail instructions. When one or both bearing-pieces are placed on top of car sides they may be located within 12 in. either side of the center line of the freight car body-bolsters.

Rule 222—The idler used with loads as shown in Figs. 54 *and* 55 may be a low side gondola car, but must have at least 4 in. clearance vertically between load and idler body or brake shaft.

Rule 247—The bolsters may be held to the turntable in the manner shown in *Fig.* 76, or if rivet holes are available in the lower flanges, they may be held with four ¾-in. bolts at each end.

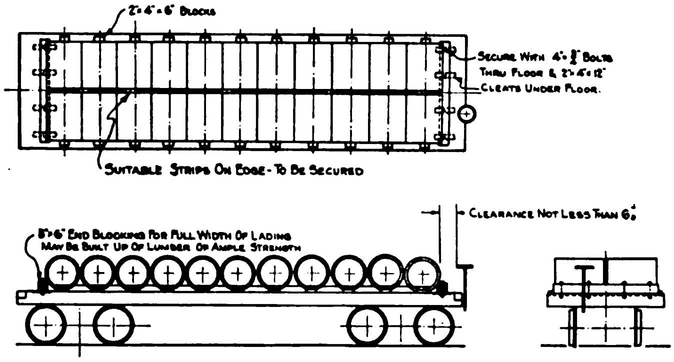

Fig. 109A—Manner of loading concrete culvert pipe on flat cars

Another method of securing the bolsters to the turntable by clamping to the inside flanges is shown on Fig. 76-A. When turntables of the straight girder type are loaded in this manner, rods to prevent end shifting must be applied as shown in the figure. The bolsters must be secured to the *car* by a center pin 2½ in. in diameter, passing through bolster, center-plates and top timber of cribbing *or floor of car.*

EXPLANATION: An alternate method of clamping the turntables to pivoted bolster has been provided at the request of the shippers.

Trial shipments showed this method of securing the turntable to be satisfactory.

Changes in rules governing the loading of boiler shells, machinery, etc.

Rule 302, New paragraph—Small diameter tanks, when more than one tank can be placed longitudinally (side by side) on flat or gondola cars shall be loaded as follows: Tanks weighing less than 3,500 lb. each may be loaded three, four, five or six tanks per pile, as per Fig. 101-A, Sections "B" and "A". Tanks weighing 3,500 lb. or over, must be loaded three tanks per pile as per Fig. 101-A, Section "B". Tanks loaded four, five or six per pile must be secured by three rods or bands per pile and when loaded three tanks per pile must be secured by two rods or bands, rods or bands must be secured to side of car, stake pockets or floor of car with suitable nuts and washers or cleats; threaded ends to be riveted over or checked to prevent loss of nuts. Rods must be at least ¾ in. in diameter, and bands must be of equivalent strength, with bolt ends welded on. Each layer of tanks, when not loaded in pyramidal form must be separated by at least two 3-in. by 4-in. bearing timbers having 4-in. by 6-in. chock blocks spiked to top and bottom of each bearing-timber. Side blocks on floor when loaded in gondola or flat cars, must be 4 in. wide by 6 in. high and applied as shown in Fig. 101-A for each pile of tanks, and when loaded on flat cars each block must be backed up by a 4-in. by 5-in. side stake. End blocking must be applied to other end of end piles. On gondola cars, the end blocking should be 4 in. by 4 in. spiked to floor with 60 penny spikes and on flat cars the end blocking should be 4 in. by 6 in. bolted to floor of car with four ¾-in. bolts with 2-in. by 4-in. by 12-in. cleats under floor. Tanks less than 8 ft. in length having flat ends, may be loaded on end in gondola cars, providing they are securely blocked and braced to prevent end shifting and falling over.

Changes in rules governing the loading of concrete culvert pipe, brick, stone, building tile, etc.

Rule 400—Manner of securing concrete culvert pipe loaded on flat cars: Pipe loaded on its side should be secured as per Fig. 109, 109-*A or* 109-*B, the method shown on Fig.* 109-*B to be followed for pipe loaded crosswise of car, when cars are not equipped with end stake pockets.* If loaded on end it should be secured as per Fig. 110.

EXPLANATION: New figures have been added to the rules to cover concrete culvert pipe loaded on its side crosswise of car. This method of loading is giving satisfactory results in actual service.

Rule 401, Second paragraph—Where separating strips to keep lading clear of car floor are referred to in these rules, they should be sound wood, not less than ***three inches*** wide by ***one inch*** thick. (The remainder of the paragraph is unchanged).

EXPLANATION: Thickness of bearing-strips changed from 1½ in. to 1 in. to overcome breakage of stone in transit.

Rule 417—Building tile, *unless otherwise covered by governing classification,* loaded interlocked at doorway do not require door protection if built up as per Fig. 113, and packed tight to prevent motion between tiling. (The remainder of the paragraph is unchanged).

EXPLANATION: Reference to the Classification has been incorporated in the rule to avoid confliction between the Loading Rules and Rule in the Classification covering this class of material being shipped.

Changes in rules governing the loading of automobiles

Rule 518, Paragraph (i)—*After* loading, emergency brakes should be set, *except on balloon tires, where it is optional.*

EXPLANATION: To set emergency brakes on automobiles equipped with balloon tires will damage the brake mechanism, due to the fact that constant jar in the car on account of the resiliency of the balloon tires would spread the brake bands when the brakes are set.

The report is signed by R. L. Kleine (chairman), assistant chief motive power, Penna.; R. H. Dyer, general car inspector, N. & W.; E. J. Robertson, superintendent car department, Soo Line; Samuel Lynn, master car builder, P. & L. E.; G. R. Lovejoy, master mechanic, Detroit Terminal; T. O. Sechrist, assistant superintendent machinery, L. & N.; C. J. Nelson, chief inspector, Chicago Car Interchange Bureau, and R. B. Rasbridge, superintendent car department, Reading.

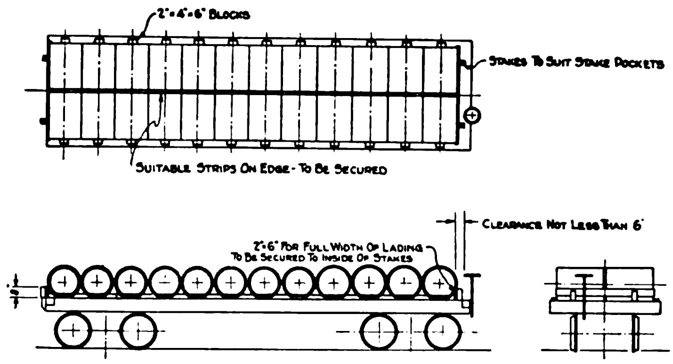

Fig. 109B—Manner of loading concrete culvert pipe on flat cars

Discussion

After presenting the report Mr. Kleine stated that the committee had a number of rules under investigation and new rules under consideration that were not completed up to the time of the convention. As the Loading Rules Committee works through the entire year, making trial loads at the request of the shippers, he asked that the members of the association consider some subsequent recommendations which the committee would make for inclusion in the letter ballot, accompanied by a full explanation.

The report was accepted subject to later changes as requested by the chairman of the committee.

Specifications and tests for materials

The report submitted by the committee recommended the withdrawal of one tentative specification, revisions of five standard specifications, revisions of eight practice specifications and the adoption of two new recommended practice specifications.

Withdrawal of specification

In 1921 the committee presented a new tentative specification for Chrome Molybdenum Alloy Steel Helical Springs. Inquiry has developed the fact that no use is being made of this specification except that one consumer had attempted to secure such springs with unsatisfactory results. The committee, therefore, recommends that this specification be withdrawn from the manual.

Revision of standard specifications

Specifications for Quenched and Tempered Carbon Steel Axles, Shafts and other Forgings, to be revised as shown. These specifications have been revised with the co-operation of the American Society of Steel Manufacturers' Committee on Axle Specifications to bring them into line with recent practice, mainly as regards form, and also to revise the section on proof tests. In the proposed modified form the two classes formerly called first class and second class according to size are changed to class A and class B. In the chemical composition the carbon content is increased slightly in class A. A change is made in the method of determining the elastic limit and the section relative to proof test has been amplified in accordance with the practice on the Pennsylvania System, New York Central Lines, Standard Steel Works Company and the Carnegie Steel Company.

In the proposed revision the paragraph covering chemical composition has been changed to show an increase in carbon and manganese, the omission of a specification for silicon and the chromium content for chrome-nickel steel decreased. The method of determining the elastic limit has been clarified and new material added relative to proof test.

Specifications for Welded Pipe to be superseded by two new specifications; one covering Welded Wrought Iron Pipe and the other Welded and Seamless Steel Pipe. This revision is for the purpose of covering wrought iron and steel pipe in separate specifications and making these specifications agree with present standard practice. The proposed specifications are more complete than the old specifications on welded pipe.

Specifications for Boiler and Firebox Steel for Locomotive Equipment to be revised so as to agree with recent standard practice and specifications of other societies. The proposed revisions change the carbon content for firebox steel, provide for a modification of elongation for material over ¾-in. in thickness by increases in 1/32-in. steps instead of by ⅛-in. steps and amplify the paragraph on marking.

Specifications for Rivet Steel and Rivets for Locomotive Tenders, Passenger and Freight Equipment Cars to be revised in agreement with standard practice as regards permissible variations in size in hot finished rivet bars.

Specifications for Carbon Steel Axles for Cars and Locomotive Tenders to be revised in order to provide additional tolerances where experience has shown such provision was necessary, and to cover certain changes in form in order to clarify the meaning. These revisions have been made in co-operation with the American Association of Steel Manufacturers' Committee on Axle Specifications. Allowable variations in turned diameters of smooth forged and rough turned axles have been increased. A change is also made in the section covering weights.

Specifications for Blooms, Billets and Slabs for Carbon Steel Forgings has the title changed to Carbon Steel Blooms, Billets and Slabs and Forgings. Chemical specifications for carbon and manganese have been revised for the purpose of bringing the different classes of steel in agreement with what is now standard. Clauses on analyses and chipping have been revised and amplified to clarify the meaning.

Specifications for Annealed and Unannealed Carbon Steel Axles, Shafts and other Forgings to be revised in order to bring the specifications in line with recent practice. The changes have been made in co-operation with the American Association of Steel Manufacturers' Committee on Axle Specifications. Modifications have been made in chemical specifications for carbon and manganese. The maximum speed of testing machine when making tension tests has been increased and provision made for three instead of only one retest. A rewording has also been made of the paragraph on workmanship.

Specifications for Malleable Iron Castings to be revised in order to bring them into agreement with current standards. Revision increases the minimum allowances for tensile strength and for elongation. Provision is also made for retests when bars fail on account of flaws.

Specifications for White Lead for Lettering to be revised in order to bring the specifications into agreement with current practice. Under chemical composition where it is now specified that the mechanical moisture combined with pigment and oil shall be not over 0.25 per cent by weight, it is changed to read, not over 0.70 per cent by weight.

Specifications for Boiled Linseed Oil to be revised in section 7. Loss on Heating by changing temperature figures of 115 to 125 deg. C. to read 105 to 110 deg. C.

Specifications for Raw Linseed Oil to be revised the same way.

Specifications for Turpentine to be revised in the paragraphs covering appearance, color and odor, also revision in paragraph 6 on other properties.

New recommended practice specifications

New specifications were submitted for Water Gage and Lubricator Glasses. These specifications cover three types of water gage glasses, namely, reflex, tubular and "bull's-eye," also "bull's-eye" type lubricator gage glasses. Specifications for physical properties and tests include optical test, dipping test, solubility test, pressure test and method of taking samples. Additional points cover permissible variations, workmanship and finish, wrapping and labeling, and inspection and rejection.

New specifications were submitted for Paint Reducing Oil used for mixing paste and semi-paste to the proper consistency of painting. The reducing oil to consist of not less than 35 per cent of fixed oil and drier with the remainder mineral spirits. The fixed oil to contain at least 50 per cent linseed oil, the remainder being drying or semi-drying oils. Specifications cover also special requirements, drying tests, elasticity test, number of tests and inspection and rejection.

The report is signed by F. M. Waring (chairman), engineer tests, Pennsylvania System; J. R. Onderdonk, engineer tests, Baltimore & Ohio; Frank Zeleny, engineer of tests, Chicago, Burlington & Quincy; A. H. Fetters, mechanical engineer, Union Pacific; H. G. Burnham, engineer of tests, Northern Pacific; J. C. Ramage, engineer of tests, Southern; J. H. Gibboney, chemist, Norfolk & Western; F. T. Quinlan, engineer of tests, New York, New Haven & Hartford; T. D. Sedwick, engineer of tests, Chicago, Rock Island & Pacific; G. N. Prentiss, engineer of tests, Chicago, Milwaukee & St. Paul; H. W. Faus, engineer of materials and equipment tests, New York Central; H. D. Browne, engineer of tests, Chicago & North Western.

Discussion

E. E. Chapman (A. T. & S. F.) said that the change in chemical specifications for firebox steel, which calls for the elimination of the lower limit in carbon is a step in the right direction but believed that consideration should be given to the lowering of the maximum limit for the carbon content for plates ¾ in. or under in thickness to not over 0.18 per cent and for plates over ¾ in. in thickness to not over 0.25 per cent carbon.

The committee recommended that the manganese in the thin plates have the upper limit reduced to 0.50 per cent in place of the present 0.60 per cent. Mr. Chapman objected to this recommendation because the manganese in moderate quantities is a cleanser of sulphur and phosphorus and produces greater resistance to the formation of cracks.

On motion, the report was accepted and referred to letter ballot of the division.

Report on safety appliances

Mr. Chambers: The committee has no written report this year. The principal work we have been engaged in is the arrangement for testing out the air brakes to comply with the Commission's requests in power brake appliance hearings. H. A. Johnson, our director of research, has a statement to make.

H. A. Johnson: The Director of Research was appointed in the early part of December, 1924, and instructed by the Committee on Safety Appliances of the Mechanical Division to proceed upon the following plan:

1—Steps will be taken to obtain appliances, which, it is claimed, meet the views of the Interstate Commerce Commission, as indicated in its preliminary report and conclusions. If the plans or specifications for such appliances are available and the appliances are not yet being manufactured, steps will be taken by the Director of Research to secure such appliances, even to the extent of entering into an agreement to have such appliances made.

2—As soon as such appliances have been obtained they will be given exhaustive tests on the test rack at Purdue University, which rack will be completely prepared and brought up to date for the purpose of this investigation.

3—Following the completion of the rack tests such devices will be given road tests, to develop whether or not they meet road conditions safely in service.

4—This program will be carried out with all dispatch and as promptly as the devices for these tests are available.

5—The investigation will also embrace such further study as may in the judgment of the Director of Research throw further light upon this problem.

In response to inquiries sent to the Westinghouse Air Brake Company, the Automatic Straight Air Brake Company, and the New York Air Brake Company, the American Railway Association has purchased from each of the first two named companies 150 sets of freight air brake equipments, which, it is claimed, meet the views of the Interstate Commerce Commission as indicated in its preliminary report and conclusions. Both companies are now manufacturing these equipments.

A contract between the American Railway Association and the Purdue University Engineering Experiment Station has been entered into covering the use of the facilities of the University during the rack tests, which will be made upon the American Railway Association test rack. The test rack has been redesigned and is now being rebuilt to represent two Type ET locomotive equipments and 100 modern freight car equipments. The test rack is being arranged to accommodate the several types of equipment which will be submitted for test and this necessitates lengthening the rack 25 per cent. An order has been placed with the Westinghouse Air Brake Company covering the two Type ET locomotive equipments and the necessary material for placing the rack in first-class condition. Practically all of this material is now at the University or has been shipped. The length of brake pipe per car is being increased from 42 ft., center to center of hose couplings, to 50 ft., center to center of hose couplings, which more nearly represents average present day conditions.

In the conduct of these tests automatic recording instruments will be used, wherever possible, to eliminate the human element in reading and recording results. As there were no instruments on the market suitable for this work, it has been necessary to design and develop new instruments. These instruments are now being manufactured.

The drafting of a schedule of tests, to which the various equipments will be subjected, is well under way. This schedule will include the American Railway Association code of tests and such additional tests as are necessary to develop the additional functions provided for in the preliminary report and conclusions of the Interstate Commerce Commisison. Upon completion the schedule of tests will be submitted to the Bureau of Safety of the Interstate Commerce Commission, the manufacturers submitting equipment and the Committee on Brakes and Brake Equipment of the American Railway Association, for their criticism and suggestions. It is to be understood that the schedule of tests may be modified or revised as the tests progress, if such modification appears desirable in the opinion of the Director of Research. The present standard Type K freight equipment will be tested first in order to establish a proper basis for comparative results. The Type K triple valves, which have been installed on the test rack for a number of years, will be replaced by the Westinghouse Company with new Type K triple valves.

It is expected that the rack tests will be started during the early part of September and be completed by the end of the year. The men who will act as official observers during the tests will be selected largely from the staff of professors and instructors of Purdue University who are skilled in carrying on scientific researches and who will be unbiased in their judgment. All work performed by the University staff will be under the direction of the Director of Research, who will be responsible for the conduct of the tests and the results obtained just the same as if the observers were on his own payroll. The Bureau of Safety of the Interstate Commerce Commission, the manufacturers submitting the equipment, and the American Railway Association will be invited to have representatives present during the tests.

No definite plans have yet been made in connection with carrying on road tests, as the nature of the road tests will depend somewhat upon the results obtained on the test rack. Road tests will probably not be undertaken before next spring or summer as the rack tests will not be completed before winter sets in.

The Director of Research is making semi-monthly reports of the progress of the investigation to W. P. Borland, Director, Bureau of Safety, Interstate Commerce Commission with copies to R. H. Aishton, President, American Railway Association, C. E. Chambers, Chairman, Committee on Safety Appliances and V. R. Hawthorne, Secretary, Mechanical Division. In this manner the Bureau of Safety and the officers of your Association are kept thoroughly informed of every move made and are given the opportunity of making suggestions as the work progresses.

As many of you as possible should visit the University sometitme during the conduct of the tests, or have your air brake man drop in for a few days to see how the work is going on. I would be very glad to have you come and have your suggestions.

Report of committee on wheels

The new cast iron wheel specifications adopted in 1923 are now in general use and appear to be meeting with approval both from the users and the manufacturers. It has been found in practice that the extra requirements in these specifications, as compared with the old, have not caused the manufacturing difficulties which were anticipated by some makers. There is no question but what these specifications are proving a help in getting better wheels.

During the year your committee has discussed the question of still further increasing the requirements of the specifications, particularly as regards thermal test, in an effort to get further protection against cracked plate wheels. A considerable number of experiments must be made before any such recommendation could be presented by the committee, and it is planned to go into this question during the coming year as well as to hold conferences with the manufacturers in regard to same. Consideration will also be given to the inclusion in the specifications of a prescribed method of chemical analysis.

Developments in cast iron wheel design

During the year your committee has been watching the developments in the design of cast iron wheels. They witnessed the making of wheels with a lip chill at one foundry and examined some which had been in service for a number of years, in order to get an idea as to the relative merits of these lip chill wheels and the sand rim type. Wheels of both types were broken under the drop and examined to determine the nature of the metal at the rim. The committee came to the conclusion that the lip chill wheel is less liable to chipping of rim, and that a saving may be accomplished by its use since there are a very large number of wheels removed from service because of chipped rims.

The most interesting development in cast iron wheels is the single plate design. Tests which are being made of the 850-lb. single plate wheels in engine tender service have not progressed sufficiently to warrant the committee making any report on them. Up to the present time we know of no single plate wheels of lesser weight which have been put to service, but we anticipate that some such wheels will be produced and are hopeful that they will prove a help in the reduction of cracked plate wheels, particularly in high speed freight service, such as in refrigerator cars. There has undoubtedly been a radical improvement in the cracked plate wheel situation since the adoption of the heavier arch plate designs. However, cracked plates are still a problem and your committee hopes to co-operate with the manufacturers in an effort to still further improve the designs of the wheels.

Grinding of cast iron and steel wheels

Your committee made a series of tests on a wheel grinding machine in the shops of one of the member railroads. The grinding machine is built by the Norton Company, Worcester, Mass. The machine is motor connected by chain drive to a shaft which in turn is connected to the grinding wheels and drive for wheels in lathe by flexible leather belts. The grinding wheels cost $27.52 each and average about 200 slid flat cast iron wheels before they are replaced by new grinding wheels. The machine is operated by one man employed at a rate of 62 cents an hour.

Grinding cast iron wheels removed from service on account of slid flat spots, the lathe will average two pairs of wheels per hour or 16 pairs per eight hour turn. Grinding steel wheels removed on account of slid flat spots, the average output would be

somewhat greater as the time required per pair of steel wheels is less than per pair of cast iron wheels. Grinding new cast iron wheels to insure rotundity, the output is four pairs per hour or 32 pairs of wheels per day average.

The second pair of new wheels applied in the lathe were cast by the Griffin Wheel Company for refrigerator car service, 700 lb. wheels, September 15 and September 26, 1924, tape 3, A. R. A. 1917. Application of a gage prior to the grinding operation indicated lack of rotundity of about 1/32 in. During the grinding, this out of round condition became apparent as soon as the grinding wheel was applied to the wheel tread and wheels were revolved in the lathe. It should be noted that unless a gage is used, a considerable number of new cast iron wheels would be swung into the grinding machine needlessly. Considerable labor and time can be saved by the use of a rotundity gage applied to the journal with contact point in the center of the wheel tread, the wheels to be rolled on the track and the contact of the gage point with the tread noted.

Grinding slid flat rolled steel wheels

A pair of slid flat rolled steel wheels with good flanges were selected for test and one wheel of the pair was ground to correct the slid flat spots, the mate wheel later being turned in a wheel turning lathe. On the first wheel, one slid flat spot was 3 in. in length and two additional spots totaled 4 in. in length. The grinding operation resulted in a loss in wheel diameter of 1/16 in., a reduction in tape size from 262 to 260½ or a loss in service metal of 1/32 in. The mate wheel, with a slid flat spot 3¼ in. in length, was placed in a turning lathe for turning in accordance with ordinary practice. The saving in service metal for the pair of wheels if ground instead of turned would amount to 3/16 in. service metal per wheel at $2.03 or 6/16 in. for the pair of wheels, which represents a total saving in value of service metal of $12.18. It should be noted further that the labor for the grinding operation was less than one-quarter hour at 63 cents per hour for grinding as compared to a labor item of three-quarters hour at 75 cents per hour for the turning operation is a considerable saving over the old method.

One of the principal objections which has been raised against the practice of grinding slid flat wheels has been based on the fear that a ground wheel would develop a comby spot at the same location as the original flat spot due to thermal cracks. The best answer to this contention is the experience of those roads which have been following this practice for many years. This shows that these comby spots do not develop. In fact the records show that some wheels have been ground three times. It is important however that the wheels to be ground be carefully selected and only those in good condition except for the flat spot be ground. No shelled, comby or badly tread worn or flange worn wheels should be considered for the replacing of these wheels after grinding would not be considered good practice.

It is estimated that a grinding machine, completely installed, will cost $10,000. It is interesting to note that it has been the experience of one road that a large percentage of the cast iron wheels removed on account of slid flat spots were new wheels. This is probably due to the tendency of out of round wheels to be bound in the trucks by the brake shoe application resulting in slid flat spots in cast iron wheels. It follows naturally that when new wheels are placed in the machine and ground after mounting, the number of wheels removed on account of slid flat spots would be reduced to a considerable extent and that further the loss incident to scrapping of new cast iron wheels removed from service on account of slid flat spots is greater than appears to be the case when considering the difference in value between new cast iron wheels and second hand cast iron wheels than scrap cast iron wheels under A. R. A. Rules of Interchange. For instance, the A. R. A. price quoted for 750-lb. cast iron wheels new is $17.40; second hand value $9.55; and scrap $6.30. To reclaim the wheels as second hand rather than scrap results in a saving of $3.25 per wheel or $6.50 per pair, but this does not represent the actual saving for wheels reclaimed after removal from service on account of slid flat spots on comparatively new wheels. Furthermore, these wheels are better than the average second hand wheel since wheels with badly worn flanges, brake burns, etc., are not ground. To the actual saving of $6.50 in value of the wheels should be added the saving represented by cost of dismounting, remounting, boring, etc., and other operations necessary for the completion of the work.

Cost of grinding slid flat cast iron wheels

Labor ½ hour at 62 cents	31 cents per pair
Interest and depreciation at 10 per cent, $10,000 first cost (1924 price), 3,000 pairs ground per year	33 cents per pair
Power 12 k.w.h. at 1½ cents	18 cents per pair
Grinding wheels at $55 per pair	37 cents per pair
150 pairs wheels ground per pair grinding wheels	
	$1.19 per pair
Saving per pair based on second-hand values	$5.31
Saving per pair based on new values	$21.01

Gage for re-mounting wheels

There has been considerable controversy in regard to the use of the cast iron wheel re-mounting gage shown on pages 45 and 46 of Section B of the Manual. It appears that these gages have been used improperly by some railroads and such use has resulted in the wastage of serviceable material. This gage provides for a satisfactory and definite way of classifying second hand cast iron wheels as between scrap and second hand for billing purposes. It was never intended for steel wheels, though some of the roads have been using it in their shops for this purpose. In order to clarify this matter, the committee recommends that the title for this gage be changed to read: "Limit Gages for A. R. A. Billing Classification of Second Hand Cast Iron Wheels." (The committee felt that there was no need for both of the remounting gages shown on page 45 (Section B) of the Manual and recommended that the second figure on this page be eliminated and the title under the first changed so that it will refer to all cast iron wheels. Since the maximum wear limit on flanges is 1 7/16 in., it was also felt that 1 5/16 in. is a fairer limit than 1 3/16 in. The committee report also included an explanation of Interchange Rule 24, and some important recommendations regarding the mounting of wheels, the use of pressure gages for wheel presses and mating of steel wheels.—Editor.)

Questionnaire on steel wheel wear and contour

In accordance with the committee's 1924 report, a questionnaire was sent to all railroads to gather information as to their practice regarding tread wear of steel wheels and also as to the desirability of using a standard contour for driving tires and all other wheels, particularly to determine if a 1 in. flange height for driving tires would be satisfactory. This questionnaire developed the fact that there was a great difference of opinion on these questions. The vote was approximately evenly divided for and against the 1 in. flange on drivers, though the majority stated that it would be advantageous from a shop viewpoint. Your committee is of the opinion that the 1 in. flange, which incidentally is being used by a number of roads and is used on engine truck wheels, should be standardized. However, in view of the large number of roads opposing such practice, your committee will not make such recommendation at the present time, but will continue its observation of results secured by those roads who are using this type of flange on driving tires.

Steel wheel specifications

During the past year your committee has given a large portion of its time to the consideration of wrought steel wheel manufacturing processes. A sub-committee has visited the plants of most of the manufacturers and studied the various processes used. We have also held a conference with the representatives of the different manufacturers and upon our request they have formed a technical committee to work with your committee in the development of the wrought steel wheel. A suggestion was made that the specifications be changed to include a number of new requirements regarding process of manufacture. After a conference with the manufacturers, your committee decided that a better procedure would be to work out the various problems involved through the technical committee and leave the specifications as they are, at least, for another year, pending the results of these further studies. The service to which steel wheels are being put is becoming more and more exacting, particularly in locomotive tenders, and improved processes are necessary to fully meet these requirements. We are glad to report that the manufacturers, by the formation of this Technical Committee, are showing a spirit of co-operation in working toward a solution of these difficulties and we are very hopeful that the next year will produce changes and improvements which will prove most helpful to the users of wrought steel wheels.

Your committee has found that there are very few 38 in. wrought steel wheels now in service and they therefore recommend that such wheels be removed from the standards of the Association.

Limits of wear on rolled steel wheels

At the last meeting the committee recommendation to reduce the limit of wear for rolled steel wheels in switch engine tender service was approved. The matter was referred to Mr. Pack of the Interstate Commerce Commission and he has issued a ruling permitting this lower wear limit under the I. C. C. Inspection Rules. The railroads are therefore able to take advantage of this further saving of wheels.

The committee was requested to consider reducing the limit of wear on all tender wheels and also on all passenger wheels. Though all the reports indicate that no trouble is being experienced with the lower wear limit in freight cars, your committee does not feel that sufficient experience has been had with these lower limits to warrant their making such recommendation at this time. We wish to protect passenger car and engine service in every possible way and it should be remembered that passenger car wheels worn to 1 in. need not be thrown away as they can then be transferred to freight service. All of the roads are not taking advantage of this possible extra service of wheels, and the committee urges that they give it consideration.

The rolled steel wheel is not permitted to be worn under passenger cars or under tenders of road engines to less than 1 in. rim thickness. It is probable that this amount of dead or unused metal is more than safety requires. This limit was established in the days when steel wheels were mostly steel-tired with an independent center. This type of wheel did not have the strength in the rim which is possessed by the single plate rolled steel wheel of today. It seems reasonable that the rim of the more modern rolled steel wheel can be worn to a thinner section than can the rim of the steel tired or assembled wheel. If this is correct, the present standard of 1 in. thickness at which rolled steel wheels are condemned from passenger service and road engine tenders, wastes some metal in each wheel.

In order that the railways may be supplied with the best information available as to what is safe and advisable in this matter, it is recommended that a questionnaire be sent each railway for its filling out with the results of its experience and its views. This questionnaire is to be worded so clearly that it cannot be misunderstood, and to develop data which can be compiled on a common basis for conclusions.

Manual of wheel shop practice

In accordance with statement made in our 1924 report, we have prepared a manual of wheel shop practice. The committee has devoted a large amount of time to the preparation of this book and we are presenting it for your consideration at this time with the understanding that it is not a fully finished piece of work. The section covering classification and causes of defects is particularly needful of further study and development. The committee believes that thru co-operation with the technical committee of the wrought steel wheel manufacturers during the coming year more conclusive information will be developed. Undoubtedly, there will be found many features which can be improved upon and the committee presents it with the request that during the coming year the members furnish criticisms and suggestions for changes and it is hoped by the end of another year the committee can revise the Manual so as to put it in finished shape for issuance to those interested.

(The committee here inserted a copy of the proposed manual of wheel shop practice, which is profusely illustrated and contains 20 main subdivisions of this important work. It forms a 100-page booklet.—Editor.)

The report was signed by C. T. Ripley, chairman, chief mechanical engineer, A. T. & S. F.; O. C. Cromwell, assistant to chief of motive power and equipment, B. & O.; H. E. Brownell, general foreman foundry, C. M. & St. P.; G. B. Koch, general foreman foundry, Penna.; H. W. Coddington, engineer tests, N. & W.; A. Knapp, inspection engineer, N. Y. C.

Discussion

The discussion of this report was opened by Mr. Ripley, who stated that the committee wished to withdraw the recommendation that the title of the remounting wheel gage be changed, as this might cause controversy.

A. H. Fetters (U. P.) read a prepared discussion by O. S. Jackson (U. P.), in which he commended the disposition made of the question of the proper limit for wear for rolled steel wheels under switch engine tenders, stating that with the new method many dollars will be saved. He went on further to state that one of the most perplexing and annoying problems coming to the attention of the railroads has been the large proportion of rolled steel wheels removed from heavy road tenders on account of being shelled out. While admitting the heavy loads imposed, it seems that the material is not what it should be and offers an opportunity for investigation by the wheel committee during the coming year.

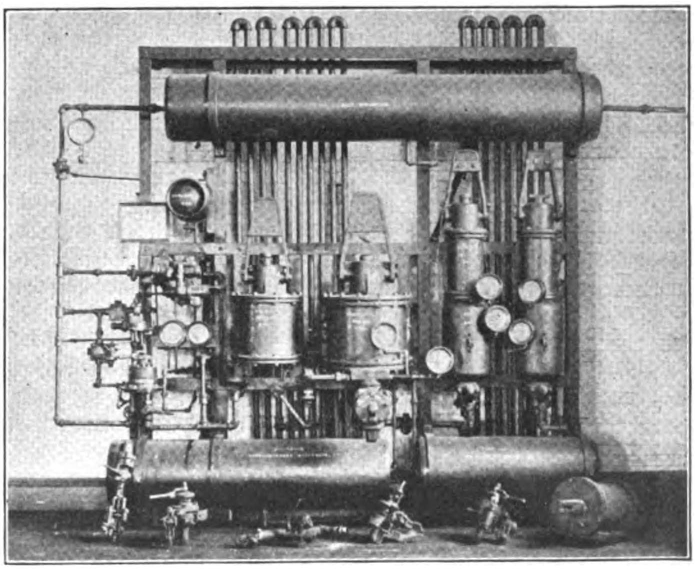
A. E. Calkins (N. Y. C.) presented a prepared discussion. He stated that with a few minor exceptions, the 1923 cast iron wheel specifications were incorporated in the New York Central specifications as of January 1, 1925, and present indications show that excellent results may be anticipated from these wheels. He said that the remounted gages shown in the manual have never been used on his road for remounting determinations, as the flange thickness requirement of these gages is too severe and if recognized would result in an alarming economic loss.

The N. Y. C., he said, intends to try out the wheel axle centering gage as it is superior to the existing method of measuring. He took exception to the suggestion that a more general use of hydrauligraphs be obtained through a provision in the interchange rules, stating that it is N. Y. C. practice to insist on the general use of the autographic type and to require press operators to show the axle size as well as the wheel number in order to carry out the checking of wheel mounting data in the general offices in addition to the surprise checks made during the day.

Mr. Calkins expressed the hope that during the coming year the wheel committee would investigate and incorporate in the manual some further data and perhaps drawings of fillet gages for various journals which will tend to increase the life of axles. He also suggested that the committee include in the manual a provision to the effect that wheel shops should stencil on each end of the axle inside of the wheel seat, the actual diameter of each wheel seat. This, he said, proves of great value to billing clerks at shops where wheels are applied.

Interesting comments were made by G. S. Goodwin (C. R. I. & P.) pertaining to the grinding of slid flat wheels. He stated that for the past month, his road had tried out with success a new portable wheel grinder reclaiming slid flat wheels by grinding off the high spots on a 14-in. arc on the wheel circumference. On 12 pairs of wheels ground, he said, a total of 251 min. was required, which gave an average of 21 min. per wheel at a cost of 40 cents which did not include electrical current or shop prorata; the flats varying between 2½ in. and 3 in. and the metal removed ranging from 3/64 in. to 1/16 in. All of the wheels thus ground, he said, had been restored to service on the road's own equipment and up to the present time, no reasons have been discovered why this treatment should not be continued.

The report was accepted and referred to letter ballot.



Air brake demonstration equipment used for instruction purposes at Yale University

Character of wheel and rail contact

Above critical speed flat spots or track depressions cause contact failure — Spring supported brakes amplify this condition

By John P. Kelly

Senior engineer, Bureau of Signals and Train Control Devices, Interstate Commerce Commission

THE sliding of wheels while brakes are applied for the purpose of controlling the motion of a train is a decidedly objectionable occurrence which should be provided against mechanically as effectually as possible. Everyone fairly well informed concerning the braking art knows that it is on the practically continuously maintained frictional resistance between the wheel and the rail, during the time the brake shoes are pressed against the wheel peripheries that the brake is dependent for its efficacy in retarding the motion of the train.

If the magnitude of the frictional force excited between the wheel and the rail during the time brakes are applied, acting to keep the wheel rotating, is constantly maintained

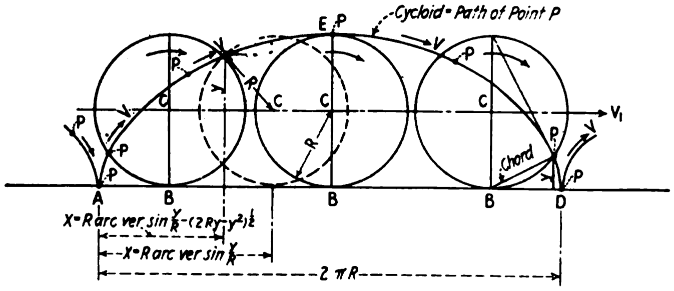


Fig. 1

equal to the brake shoe frictional force, acting at the periphery of the wheel to stop its rotation, the vehicle will come to a stop without wheel sliding.

Experiment has amply demonstrated that the coefficient of friction which exists between the wheel and the rail, while the former is motionless, is about 0.32 of the weight resting on the rail under the wheel at the point of contact; hence the maximum resisting force which the brake can oppose to starting the car from a state of rest must equal the weight carried to the rail multiplied by this coefficient. While a car is in motion, assuming that the wheel and rail contact is constant and also that the weight carried to the rail is constant and equal in magnitude to that impressed upon it when the car is motionless, could we develop a braking frictional force at the periphery of the wheel equal to 0.32 of the weight of the car we should then be able to stop it on a level track from a speed of 60 miles per hour in a distance of about 376 ft. and in 8.5 seconds from the point and from the instant of application of the brake.

In the theory of train braking the first and most important consideration is, then, that of the character of the wheel and rail contact, whether constant or intermittent, while the car is in motion; and if intermittent, to what degree it is so and why. In what follows the ideal and the actually existing conditions touching upon this matter will be considered.

Theoretically, a perfectly circular wheel, rolling without slipping on the surface of a perfectly level track at any speed, will always have its rail contact point stationary with respect to the rail.

Let the circle shown in Fig. 1 start to roll in the direction indicated by the arrow, the point P being in contact with the straight line $A\ D$ at the commencement of the rolling motion. At the completion of one rotation the center C will have moved parallel to the line $A\ D$ a distance equal to $2\ \pi\ R$ the circumference of the circle, R being the radius and $\pi = 3.1416$, being the ratio of its circumference to its diameter.

The point P, during this rotation, will have turned through one complete revolution about the center C; it will also have advanced horizontally the same distance as the center C, and be again in contact with the line $A\ D$ at D. The path in space traced out by point P during this rotation is indicated in the curve $A\ E\ D$, which curve is the well known cycloid.

It is evident from an inspection of the figure that when P comes to the line $A\ D$ it is motionless with respect thereto, for, the rotation continuing, the direction of the

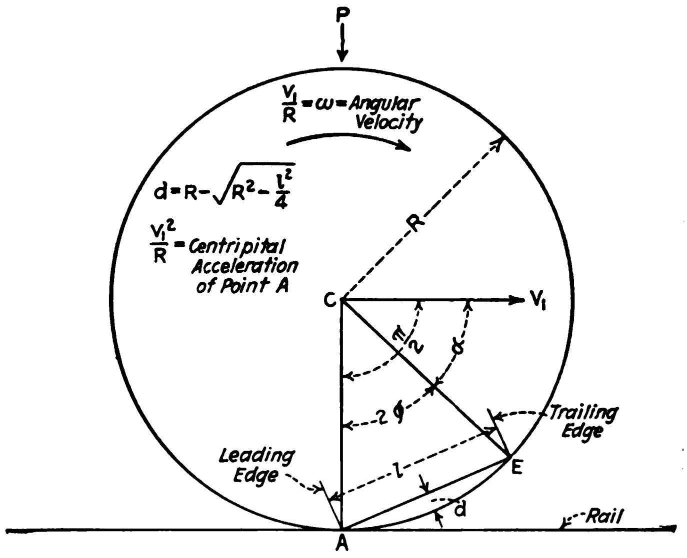

Fig. 2

motion of P changes to the opposite of what it was in coming to the line. This fact, as well as that of the variable cycloidal velocity of P at different points in the curved path may be proved mathematically. Referring to Fig. 1.

Let V = the velocity of point P at any position in its cycloidal path,
V_1 = the velocity of the center parallel to the line AD,
R = the radius of the circle,
x = the abscissa which coincides with the point of contact on line AD, on which the circle rolls, and
y = the ordinate to any point of the cycloid. The center C moves at the same rate as the successive points of contact B, and it is always vertically over B.

From the equations of the cycloid shown in Fig. 1 and the theory of curves it may be demonstrated that

$$V = \sqrt{\frac{2y}{R}} \times V_1$$

Hence if $y = O$ then $V = O$, the contact point is motionless with respect to the line AD

$y = R$ then $V = \sqrt{2}\, V_1$

$y = 2R$ then $V = 2V_1$

$y = \frac{R}{2}$ then $V = V_1$

The velocity of any point in the circle, corresponding to or coinciding with any point in the cycloidal curve, is the same with respect to the straight line on which the circle rolls as that which it would have if the whole circle revolved about the point of contact at the same angular velocity as that of the generating circle itself. For the length of the chord which corresponds to the ordinate y, Fig. 1, (at the right) as may be easily discerned from its geometry, equals $\sqrt{2\,Ry}$, and hence if

$$V : 2V_1 :: \sqrt{2\,Ry} : 2R$$

We again have $V = \sqrt{\frac{2y}{R}} \times V_1$

From the foregoing it is clear that, at the instant any point of the circle is in contact with the line, it has no velocity with respect thereto, and the velocity of the highest point, diametrically opposite the contact point, is twice that of the center.

Cause of intermittent wheel and rail contact

Were this ideal condition to obtain practically for the car wheel rolling along the rail surface, then no justifiable exception could be taken to the statement so generally made, that the coefficient of friction between the rail and the wheel has the same constant value while the wheel is rolling as it has while the wheel is motionless. Unfortunately, however, this ideal condition never obtains in practice for the rolling car wheel, and because it does not, the wheel and rail contact pressure, while a car is in motion, is of a variable and intermittent character.

We shall now consider the conditions which affect rail contacting of the rolling car wheel, using the case of the rotating flat wheel for illustration. This will enable us, although it is not of prime importance here, to determine at the same time the striking velocity of the flat's trailing edge.

Car wheels, as customarily assembled in trucks, always carry a spring supported load, a fact that should be kept in mind during the discussion which follows:

Referring to Fig. 2, let

R = radius of the wheel in feet,
l = length of flat spot in feet.
d = depth of flat spot in feet,
V_c = criticial speed of the wheel in feet per second,
V_1 = velocity of the center of the wheel, parallel to rail, in feet per second,
V_s = striking velocity in feet per second of the trailing edge of the flat spot,
ω = angular velocity of the wheel,
P = pressure of the truck equalizing spring, in pounds, on the wheel (considered the same as when the wheel is stationary),
W = Weight of wheel in pounds (this weight to include weight of all parts of the truck not spring supported),
g = acceleration of gravity = 32.2 feet per second per second

Then,

$$d = R - \sqrt{R^2 - \frac{l^2}{4}}$$

$$a = \frac{\pi}{2} - 2\,\phi = \frac{\pi}{2} - 2 \text{ arc sin } \frac{l}{2R}$$

When the wheel is in the position shown in Fig. 2 it is instantaneously turning about the point A, the leading edge of the flat spot, and the resultant vertically upward acceleration of $A = \frac{V_1^2}{R}$ feet per second per second. The whole wheel has, at the same instant, due to the downward pressure of the truck equalizing spring, avertically downward acceleration equal to

$$\frac{P + W}{W} \times g = g_1 \text{ feet per second per second.}$$

The upward acceleration $\frac{V_1^2}{R}$ and the downward acceleration g_1 are directly opposed to each other; hence the critical speed for point A will occur when the magnitude of the opposed accelerations are equal, that is, when

$$V_1 = V_c = \sqrt{g_1\, R} \text{ feet per second.}$$

Before the critical speed is attained the striking velocity of point E, the trailing edge, will be given very nearly by the expression

$$V_s = \frac{l}{R}\, V_1$$

from which it is clear that for any given wheel and flat spot the velocity with which the trailing edge will strike the rail will increase proportionately with the speed from

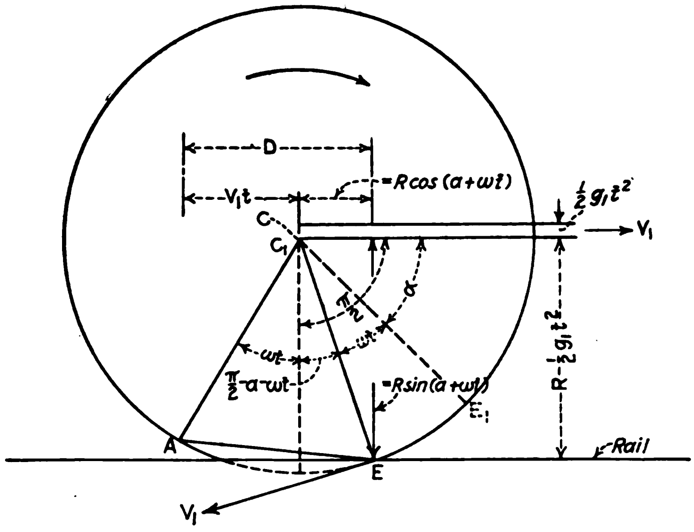

Fig. 3

zero up to the critical speed, that is, up to when

$$V_s = \frac{l}{R} \times \sqrt{g_1\, R} = l\sqrt{\frac{g_1}{R}}$$

after which, as the equation shows, it remains practically constant regardless of increase of velocity. This means, of course, that after the critical speed has been slightly exceeded the leading edge of the flat spot rises off the rail before the trailing edge strikes it, that is, the wheel breaks its rail contact at the flat spot completely.

In view of the important part which the truck equalizing springs play in the prevention of wheel sliding during brake applications made to control the motion of the car, the following explanation of the fact that the leading edge of the flat does actually rise off the rail before the trailing edge strikes it, is submitted:

When the velocity of the wheel's rotation has reached the value where

$$V_1 = V_c = \sqrt{g_1\, R}$$

let t seconds equal the elapsed time betwen the rising off the rail of point A and the striking of point E. During this interval the path of E will be the resultant of three distinct motions (see Fig. 3), namely:

1—Translation; that of the wheel as a whole which moves V_1t feet horizontally forward:

2—Vertically downward as a whole $\frac{1}{2}g_1t^2$ feet; and one of

3—Rotation, or angular motion ω, that of the wheel about its own center through the angle ωt during which E moves from E_1 down to the rail at E. Hence

$$\frac{1}{2}g_1t^2 + R\sin(a+\omega t) = R \quad \text{(1)}$$

The distance between the point of departure of A and the point of striking of E is

$$D = V_1t + R\cos(a+\omega t) \text{ feet.}$$

At the instant of striking, the vertical downward velocity of the whole wheel is g_1t feet per second. The velocity of E, due to rotation about the center C is V_1, perpendicular to CE. Its vertical component is

$$V_1\cos(a+\omega t)$$

Therefore, the vertical striking velocity of point E, the instant it comes to the rail, is

$$V_s = g_1t + V_1\cos(a+\omega t) = g_1t + R\omega\cos(a+\omega t) = g_1t + R\omega\sin\left(\frac{\pi}{2} - a - \omega t\right)$$

But since $\left(\frac{\pi}{2} - a - \omega t\right)$ is a very small angle we may say

$$V_s = g_1t + R\omega\left(\frac{\pi}{2} - a - \omega t\right) = t(g_1 - R\omega^2) + R\omega\left(\frac{\pi}{2} - a\right) \quad \text{(2)}$$

From equation (I)

$$\frac{1}{2}g_1t^2 + R\cos\left(\frac{\pi}{2} - a - \omega t\right) = R$$

and as before $\left(\frac{\pi}{2} - a - \omega t\right)$ being small we may place

$$\frac{1}{2}g_1t^2 + R\left[1 - \frac{\left(\frac{\pi}{2} - a - \omega t\right)^2}{2}\right] = R$$

so that solving for t we get

$$t = \frac{\frac{\pi}{2} - a}{\omega + \sqrt{\frac{g_1}{R}}}$$

Substituting this value of t in (2) we obtain

$$V_s = \left(\frac{\pi}{2} - a\right)\left[\frac{g_1 - R\omega^2}{\omega + \sqrt{\frac{g_1}{R}}} + R\omega\right]$$

$$= \left(\frac{\pi}{2} - a\right)\left[\frac{g_1 + R\omega\sqrt{\frac{g_1}{R}}}{\omega + \sqrt{\frac{g_1}{R}}}\right]$$

$$= 2\ \text{arc sin}\ \frac{l}{2R} \times \sqrt{g_1R}$$

For small flats, three inches or less in length.

$$\text{arc sin}\ \frac{l}{2R} = \frac{l}{2R}; \text{ therefore}$$

$$V_s = 2\frac{l}{2R} \times \sqrt{g_1R} = l\sqrt{\frac{g_1}{R}},$$

as before stated, showing conclusively that after the critical speed is exceeded the entire weight carried to the rail by the wheel is removed therefrom at each revolution, as the flat passes directly under the wheel's center; and that the striking velocity of the trailing edge of the flat becomes practically constant and independent of the speed of rotation.

For a 36-in. wheel, having a 2-in. flat, which carries a spring supported load of 12,500 lb., and under the spring 1,250 lb., the critical speed at which the leading edge of the flat rises off the rail is about 22 ft. per second or about 15 miles per hour; and the constant striking velocity of the trailing edge of the flat spot is about 2.5 ft. per second.

Practically, all car wheels may be said to have infinitesimally small flat spots in their peripheries; that is, their peripheries are never geometrically perfect circles however carefully they may be formed in the molds or turned in the lathe. Again, when the wheels are mounted on their axles the geometrical axes of the wheel and axle rarely coincide so as to be identical, although it is only in rare cases that the peripheries of wheels vary sufficiently from being perfect circles or the axes from coincidence to make the difference of great moment; but these points are mentioned merely to show that so far as the wheel is concerned it does not, even if it were rolling along a perfectly level rail surface, carry to the rail during every instant of time and at every point in its periphery, above certain critical speeds, a uniform pressure the equivalent of the load it is carrying, and this for the same reasons that, as just explained, the flat wheel does not do so.

A casual glance along the surface of the track of any railroad will disclose more or less undulating variations in it, the magnitude of which will depend largely on the character of maintenance, and on weather conditions generally; the character of the rail surface is a consideration of very great weight, as affecting the magnitude and constancy of the pressure between the rail and the rotating wheel.

But with the best practicable track maintenance and under the most favorable weather and temperature conditions it is impossible to maintain track surface uniformly smooth and even. In track laid with brand new rail, after a period of four or five years, if the traffic be heavy, the surface of the rails will be found higher at the rail centers than at the ends, where the track is laid with even joints; and where laid with broken or staggered joints, the surface will be lower at the centers and higher at the quarters. This condition of surface results from the action of the rotating wheels over it, cold rolling the surface metal and, consequently, rendering it more or less undulating in character.

Effect of brake shoe suspension on intermittency of contact

Taking the combination of the more or less flat condition of the wheel with the uneven rail surface it is quite evident that while the speed is above the critical point, the contact between the wheel and the rail is of a highly intermittent character, and that it remains such until the velocity reduces to a point below the critical when it becomes constant and remains so until the stop.

We shall now consider the effect which a brake application produces on the wheel and rail contact intermittency where the brake shoes are suspended from some spring supported portion of the truck. *Where the brake shoes are hung under the spring, a brake application does not affect the intermittency of contact.*

Fig. 4 represents one of the wheels of a six wheel passenger equipment truck, fitted with the single shoe type of brake rigging, with the brake released, and with the brake shoes hung far below the wheel center. The truck equalizing spring is shown normally distended and in condition to provide the deflection necessary for com-

fortable riding, so that the vertically downward acceleration of the wheel is, as before shown,

$$\frac{P + W}{W} \times g = g_1$$

In Fig. 5 the same wheel and truck brake rigging is shown, with the brake heavily applied, the magnitude and direction of the resolved brake shoe pressure indicated, the resultant vertical force between the truck equalizer and the top rail of the truck frame indicated by the vector *A*, sufficient to compress the equalizing spring solid and to hold it in the solid compressed state as long as the brake remains applied with the same force.

The force indicated by the vector *B*, though normally impressed on the truck pedestal jaw, causes a high frictional resistance to vertical movement of the journal box,

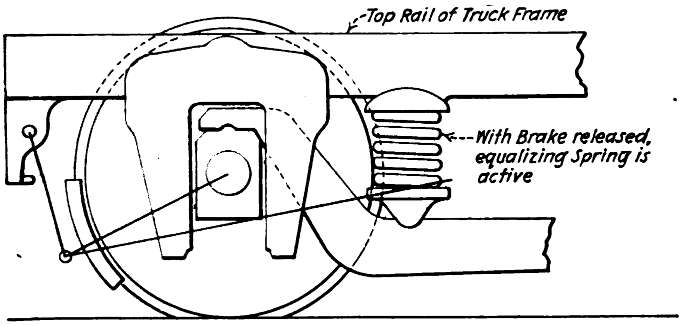

Fig. 4

and thus aids in holding the box rigid in the pedestal jaw.

Assuming that the ratio of the spring supported weight to the non-spring supported weight, or weight under the spring, is 10, the accelerating effect of the equalizing spring on the wheel, while the brake is released, as shown in Fig. 4, is 322 ft. per second per second; and when the brakes are applied, as indicated in Fig. 5, it is only 32.2 ft. per second per second.

This difference in the accelerating effect of the equalizing spring produces a condition which is highly conducive to wheel sliding; first by increasing the length of the non-contacting of the wheel and rail, and secondly by lowering the point of the critical speed.

Referring to Fig. 7, let the ratio of the spring supported

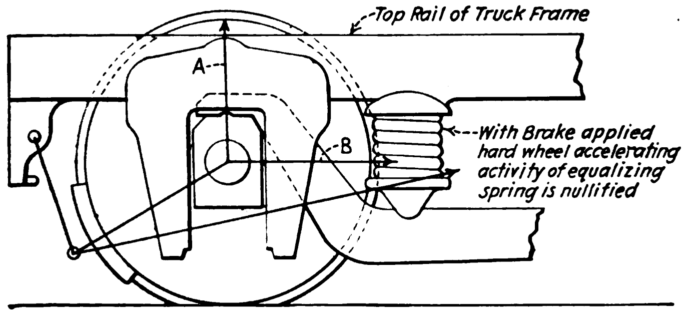

Fig. 5

weight to the non-spring supported weight be 10 as before, and the speed of the vehicle 88 ft. per second (60 miles per hour), then the wheel, if rolling into a rail depression 1/64 in. deep and of sufficient length, with brake released as indicated in Fig. 4, will lose its contact with the rail, removing entirely its pressure therefrom for a distance of 10.4 in.; if the equalizing spring be compressed solid so that the wheel and journal box is held rigid in the pedestal jaw, as indicated in Fig. 5, the contact will be lost for a distance of very nearly 33 in., so that over the distance indicated no rail frictional force is acting in opposition to the brake shoe frictional force tending to stop the wheel's rotation.

The only force during the non-contact period opposed to the brake shoe frictional force is the rotative energy within the wheel itself.

A pair of 36-in. wheels and an axle, such as is generally used in the six-wheel truck under a car weighing 150,000 lb. will weigh about 3,200 lb. The square of the ratio of the radius of gyration in such a pair of wheels and axle to the square of the radius of the wheel is about 0.55, and the rotating energy in foot-pounds of such a pair of wheels and axle at 88 ft. per second will be given by the formula.

$$E_R = \frac{W K^2 V^2}{2 g r^2}$$

in which

E_R = rotating energy in ft.-lb.
r = radius of wheel
V = linear velocity of a point r feet from the axis in ft. per second
W = weight of wheels and axle in lb.
K = radius of gyration, and
g = 32.2

Then substituting values for letters in the formula we have $\dfrac{3{,}200 \times 0.55 \times 88 \times 88}{2 \times 32.2} = 211{,}637$ ft.-lb. At 88 ft. per second, with a braking ratio of 165 per cent the coefficient of brake shoe friction is about 10 per cent. Hence, in the case of the wheel that carries a weight of 13,500 lb. to the rail we have a shoe pressure acting on

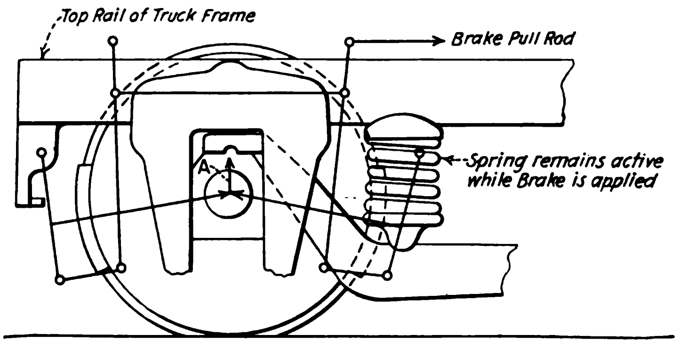

Fig. 6

the periphery of the wheel, taking the efficiency of the brake rigging at 85 per cent, of 1.65 × 0.85 × 13,500 = 18,933 lb., and the actual brake shoe frictional pull that will be exerted at the periphery of the wheel will be 18,933 × 0.10 = 1,893 lb.; and for the pair, 3,786 lb. If contact with the rails is lost for a distance of 33 in., or 2.75 ft., then the work done on the wheel while thus out of contact will be 3,786 × 2.75 = 10,412 ft.-lb.

When the wheels again come in contact with the rail at the end of the 33-in. non-contacting space their peripheral velocity will be approximately 85.5 ft. per second, or about two feet less per second than the speed of translation. Here then it may be seen that the very small depression of 1/64 in. will, under the truck brake conditions assumed, cause an incipient wheel sliding which, assisted by the various pull rods in the truck transferring weight from one pair of wheels to another, as is usually the case, will cause one or more pairs to slide.

Again when nearing the end of the stop, the truck equalizing spring remaining compressed, the critical speed instead of being 22 ft. per second becomes 7 ft. per second, or a little less than five miles per hour; so that the wheel sliding at the end of the stop, so frequently observed, and also the tendency of wheels, slightly flattened in previous stops to slide more easily in subsequent stops,

is satisfactorily explained by the compressed condition of the equalizing spring preventing continuous rail contact.

The intermittent contact and non-contact occurring in quick succession at high speed with the brakes heavily applied tends to cause rapid deceleration of peripheral velocity and, in consequence, cessation of the wheels' rotation. However, since the rotating energy of the wheels is an appreciable force and each wheel of the pair is running on a rail of its own both may not be out of contact at the same instant while the brake is acting, in which case the velocity of one wheel of the pair while it is out of contact with its rail may not be materially reduced by the brake action on account of the torsional transmission of rotative power from its mate, and of its own rotating energy. This would seem often to be the reason for freedom from slid-flat wheels in warm weather when track surface alignment is usually at its best.

During cold weather contraction of rails increases the joint spacing, and frost causes more or less additional unevenness in the rail surfaces; so that an emergency application or even a heavy service application made at high speed is very likely to cause injurious wheel sliding, flattening the wheels sufficiently to require their removal; not, of course, because the flats are long enough to cause dangerously severe rail punishment, but because of the annoying effect which the incessant pounding produces.

Comparing Figs. 5 and 6, which represent the clasp and the single shoe types of truck brake rigging, and by

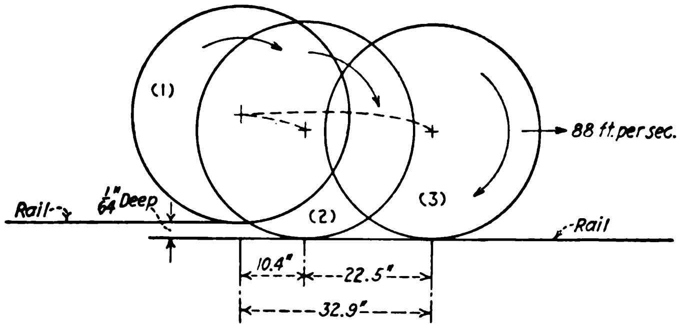

Fig. 7

(1) Wheel rolling into rail depression 1/64 in. deep.
(2) Distance of non-rail contact when equalizer spring is active, as shown in Fig. 4.
(3) Distance of non-rail contact when equalizer spring is held compressed solid, as shown in Fig. 5.

noting carefully the location of the brake shoes with respect to the wheel centers it can easily be seen that the vertical resultant of the shoe pressure, the relative magnitude of which is indicated by the length of the vectors A, is much smaller with the clasp than with the single shoe type; consequently, the clasp type will produce much less compressing effect on the truck equalizing springs than will the single shoe type; hence the clasp brake will maintain a more continuous wheel and rail contact during brake applications, and consequently there is less likelihood of injurious wheel sliding with the clasp than with the single shoe type of rigging on ordinary even surface track.

It is clear, therefore, that for the best possible continuous rail and wheel contact with any given track and wheel condition, the truck brake rigging and the brake shoes single or clasp, should be non-spring supported.

On modern freight equipment the truck brake rigging and the brake shoes are now quite generally non-spring supported, a fact which undoubtedly explains the almost entire freedom from injurious wheel sliding on freight equipment cars during brake applications made to control their speed; and if passenger and locomotive brakes were hung in a similar manner, the wheel sliding under heavy emergency applications on such equipment would be negligible, and consequently the brake efficiency could be considerably increased.

Conclusions

1—It is only for the ideal condition of rail surface with respect to evenness and for the ideal condition of wheel with respect to roundness that the coefficient of friction between the rail and the rotating wheel can be safely assumed, at speeds above the critical, to be constant in value and equal to that between the wheel and the rail when the car is motionless. Hence, all teaching respecting this point which tends to show that in practice it is, would appear to be in error.

2—Under all practical conditions of railway operation the pressure between the wheel and the rail will be variable or intermittent at all speeds above the critical, and it will vary during such speeds in quick succession between the normal maximum and zero, whether the brakes are or are not applied. If the depressions and elevations in the rail surface are of sufficient magnitude, then at high speed the non-contact rail spacing is longer than it is at low speed; hence there is a strong likelihood of wheel sliding at the higher speed during heavy brake applications.

3—If either type of truck brake rigging, single or clasp, be hung below the equalizing springs, these springs will remain as active during brake applications as they are during release; hence during brake applications the wheel and rail contact will be maintained as nearly continuous as the track condition will permit, and wheel sliding due to the brake action will be negligible with either type.

4—It being a fact that wheel sliding rarely occurs under freight equipment cars, which have the truck brake rigging non-spring supported, during brake applications made to control their speed, it is evident in connection with what has been explained in this article that a like result might be achieved for passenger equipment cars if their truck design were modified so as to provide for the non-spring support of the truck brake rigging.

5—Furthermore, the objectionable recoil of passenger trucks at the stop release of the brakes, because of the action of the brake shoe hanger in compressing the equalizing truck springs, would be eliminated, thus making for smooth stops as well as for freedom from flat wheels.

Numerous minor points which have an important influence on wheel sliding have not been touched on, but it is believed that sufficient has been said to show the important function which the truck equalizing springs and a track surface free from irregularities have to perform in efficient braking.

THE TOTAL NUMBER of locomotives, passenger coaches and freight cars built and purchased by the four groups composing the railway transportation system of Great Britain during the years 1923 and 1924, according to statistics received by the Bankers Trust Company of New York through its British Information Service, were as follows:

	Year	Built in the Companies' Shops	Purchased
Steam Locomotives....	1923	232	28
	1924	231	241
Passenger Coaches....	1923	543	29
	1924	784	71
Freight Cars	1923	17,200	4,521
	1924	26,797	6,777

The figures include a certain number of units purchased from other companies, etc., and in particular 125 locomotives purchased from the government in 1924.

Proceedings of the Fuel Association convention

Program included much of value to mechanical and operating officers—Reports of interest to former given below

A LARGE and varied attendance, which closely followed the proceedings throughout the sessions, characterized the seventeenth annual convention of the International Railway Fuel Association at the Hotel Sherman, Chicago, May 26 to 29, inclusive, as was indicated in a brief account of the meeting which appeared on page 373 of the June issue of the *Railway Mechanical Engineer*. A heavy, but well-balanced program in which was included papers and addresses of exceptional value to mechanical, operating and purchasing officers was carried through on a well-maintained schedule during the three days allotted for its completion.

The opening address of L. F. Loree, president, Delaware & Hudson appeared in last month's issue. Mr. Loree's address was followed by that of President P. E. Bast, fuel engineer, Delaware & Hudson. In the following columns will be found abstracts of Mr. Bast's address, of an address by John Purcell, assistant to vice-president, A. T. & S. F., and of several of the papers and addresses of particular interest to mechanical department officers.

President Bast's address

In reviewing the activities of this association since its inception 17 years ago, its work has been mainly of an educational character, endeavoring to present the fuel problem through its various angles to the personnel of all departments on the railroads, with a view of having them realize their responsibility in the purchase, inspection, weighing, distribution, handling, use and accounting of fuel, all of which in the end result in the greatest possible reduction in fuel costs.

We all realize the magnitude and importance of the fuel problem; it is creative work and requires initiative, ability in engineering, organization and management persistently applied. However, it is gratifying to observe that since the question of fuel conservation has been aggressively taken up by the railroads and by this and other associations, consistent progress has been made in the reduction of the amount of fuel used per unit of work in the various classes of service. In this respect we can feel justly proud of the results obtained, which reflect the excellent work on the part of management, mechanical, transportation and other departments, and all employees and others, who have contributed their share to the economical utilization of fuel. We should not lose sight of the fact that fuel conservation is an economic necessity and has far reaching direct value, not only to the railroads but to the country in general.

In this room one year ago R. H. Aishton, president of the American Railway Association, in addressing our association emphasized the importance of the saving of one pound of coal per unit of work in the combined classes of service and made us realize as never before the splendid economies that would acrue to the railroads through such saving. His address gave us a new and fuller sense of our responsibilities toward the railroads and those they serve. Our association at that time, through its officers, pledged itself to effect this saving during the ensuing year. A poster featuring this pound of coal was distributed by this association over the various railroads. The response was far beyond our expectation.

I estimate that 77 per cent of the fuel used is in freight and passenger service. Applying the known ratio of saving in these services to switch and miscellaneous service the total savings in all classes of service from efficiency alone during 1924 compared with 1923 was 10,647,000 tons, or a money value based on the average cost of fuel per ton during 1924 of $32,250,000. These

P. E. Bast (D. & H.)
president

J. W. Dodge (I. C.)
vice-president

E E. Chapman (A. T. & S. F.)
vice-president

W. J. Tapp (D. & R. G. W.)
vice-president

splendid savings are based on increased efficiency and only tell part of the story, since the major savings of the railway fuel bill were accomplished through reduction in price. For instance, in 1924 the railroads saved a total of over $93,000,000, of which 65 per cent was due to price. During the first two months of 1925 compared with the first two months of 1924 the railroads are showing a further saving in about the same ratio. Unless the economic conditions of the bituminous coal industry improve, I am concerned whether or not the railways of the United States will be able to maintain the splendid savings in fuel cost which they have enjoyed during the past two years.

While we have contributed a share in the economical and efficient use of fuel, much remains to be done. Many promising opportunities await the activities of our association by advancement of information on the fuel problem, such as through the medium of illustrated bulletins, the distribution of fuel performance statistics of the various railroads, the establishment of an economical figure in fuel consumption in the various classes of service, all of which would have a stimulating effect in creating an interest that is so vital in further solving a problem of such importance as that of railway fuel.

We are living in an age of progress and advancement. It is my hope that our association will continue to advance and prosper and that in the near future conditions will permit the working out of a plan for the endowing of a scholarship annually for the benefit of worthy young men to pursue courses in engineering and combustion.

Fundamental fuel factors

By G. M. Basford
G. M. Basford Company

To produce maximum ton-miles per hour per locomotive, per unit of total cost is the task of today. This means moving more tons faster and cheaper. It means improvement of the locomotive as a power plant to the upper limit of our knowledge, experience, vision and courage and then immediate replacement of wasteful locomotives with money-making locomotive power plants.

Hauling heavier trains faster increases the speed of operation. Increasing average freight speed increases the capacity and economy of operation of the road. It defers additional tracks. It demands high horsepower which can be and must be had at lower cost. To provide high cylinder horsepower is comparatively easy. To supply enough snappy steam for continuous high cylinder power was the problem that waited for years to be solved.

Careful attention has been given to the development of capacity for starting heavy trains. Splendid results have been obtained. This has been far from mistaken policy. The work done to raise the starting end of the drawbar-pull speed curve revealed the need for and opened the way to raise correspondingly, the speed portions of the curve.

The locomotive as a whole

Study of locomotives recent and less recent, indicates no lack of engine horsepower, but a real deficiency in steam making power, compelling wastefully high rates of combustion. Resort to double heading frequently comes from the need for two grate areas rather than two sets of cylinders. We face again the same problem that we faced 30 years ago. Then power at speeds was had at the expense of high rates of combustion and at best was limited by grate areas. This brought wider fireboxes. Heavy back ends of boilers brought the trailer truck. Rates of combustion are again excessive. Greater power at speeds is needed and additional weight accompanying larger grates must be divided between two trailer axles. The four-wheel trailer unit was developed by combustion engineers to remove the limit to further locomotive furnace progress, which means the limit to further locomotive progress.

It is fortunate for fuel conservation that more thought is concentrated on improvements in locomotives as complete units than ever before. A change has come. Standards have been raised. Lima Locomotive Works has produced startling results in its development of the 2-8-4 type. The American Locomotive Company has brought forward the three cylinder principle. The Baldwin Locomotive Works is engaging its great resources in locomotive improvement, including development of the Diesel locomotive. J. E. Muhlfeld has worked out high boiler pressure combined with compound cylinders and the water tube firebox. One of our great railroads is operating 600 locomotives with marked fuel economy by aid of limited full gear cut-off.

Single factors for fuel efficiency are numerous and very important. Space permits only brief comment on some of these elements for co-ordinated design for high power with fuel conservation.

Steam making improvements

High steam pressures promise great economies. Pressures of 250 and 350 lb. are used successfully with promise of higher pressures as water tube fireboxes develop.

Low rates of combustion are necessary. Rates on big engines today run to 150 lb. and over. This is wasteful and calls for larger grate areas to reduce this figure one-half.

Higher superheat means greater economy. It reduces the work of the boiler by improving the economy of the cylinders. Superheated steam for auxiliaries greatly reduces the drain on the fire. This economy is equivalent to increasing boiler capacity about four per cent.

Gas velocities are high. It is important to reduce them by increasing gas areas through the flues as much as fixed limits permit.

Air admission to ash pans needs careful attention. A firebox is often filled with gas over six times per second. Restriction must be avoided and spark loss must be reduced. Ash pans need about a cubic foot of capacity per square foot of grate area. Only one engine with adequate grate area now provides it.

Steam separators to remove moisture from the steam on its way to the superheater merit attention for the sake of economy. As boilers grow larger it is difficult to provide steam space for the enormously increasing volumes of steam used. It is correspondingly important to relieve the superheater of double duty, evaporating water that goes over and also superheating the steam.

The possibilities of pulverized coal as a conservation factor should not be overlooked. The use of lignite and other low grade and low cost fuels is a promising field for further development.

Steam using or cylinder improvements

Expansive use of steam in freight service may be provided by design that limits the full gear cut off. This not only saves fuel at low speeds; it results in significant increase of capacity at higher speeds. It does not involve any mechanical complication whatever. It provides additional tractive force at low speeds because it smooths out the torque curve in starting.

"Cut-off" in locomotive operation requires more attention by fuel officers than it has ever received. There is a correct, economical cut-off for every different speed of the engine, one that develops maximum power for minimum

steam at every different speed. Until recently this has been left to guess work on the part of the engineman and no two men will adjust the cut-off over a division in the same way. Perfection of power reverse gear mechanism has opened the way to large savings in properly taking advantage of steam expansion as an economy and power increasing factor. But it is necessary to indicate to the engineman the proper adjustment to be made. Cut-off adjustments have also been made automatically, controlled by the back pressure.

Trailing wheels temporarily used as tractors in starting and in helping over hard pulls reduce fuel cost per unit of work done. This principle aids greatly at the low speed end of the drawbar pull-speed curve, and in facilitating acceleration. It permits of greatly increasing ton miles per train hour by increasing operating speed. It reduces the length of time an engine (without limited cut-off) must be "full stroked" in starting and helps every engine in accelerating. It is a capacity increaser and a fuel conserver.

Machinery improvements

Many locomotive parts are unnecessarily heavy. Cast steel cylinders saved two tons in the Lima 2-8-4 type engine. Unnecessary weight restricts the weight of the boiler and robs it of some of its capacity. Weight saved in reciprocating parts reduces dynamic augment and opens the way for greater static weights on drivers.

Between lubrication and fuel there is an important relation. It is estimated that the difference in fuel required to haul a freight train of 60 cars over a division at usual freight train speeds with high grade and lower grade oil is as great as 200 lb. of coal per hour.

With the designers of locomotive power plants ready in all respects, there is no real reason why a freight engine should not be coupled to a train, haul it 1,000 miles or more, uncouple, spend 24 hours in the hands of good men who are fully supplied with facilities, return for 1,000 miles, ready to do it over again and over again. For years the Rhodesian Railway in Africa has operated freight engines 700 continuous miles with sleeping and cooking facilities in special cabooses for the crews. Their trains are slow. It should be easier for us to make long freight runs.

Of very great importance is the switch engine policy of the road. This subject merits a thorough discussion of its own. It is a combined question of machinery and of operation, both sides of it affecting lots of fuel. On a busy, congested road switch engine mileage may be as great as 25 per cent of total locomotive mileage. This suggests the best of fuel conservation attention applied to switching engines. It is financially foolish to use old road engines for switching service. Railroads perpetuating this practice have no license to urge their men to save fuel.

Operating improvements

Fuel officers are in position to aid greatly in the substitution of train direction by signal indication and in the abolition of the time killing train order, especially the "31" order that stops a train in order to tell it to proceed, also the "19" order that slows the train down for the same purpose. A slow down to a speed of 8 to 10 miles per hour is nearly as costly as a stop. Both of these orders must give place to operation by signal indication.

Fuel officers and division superintendents, signal officers and train dispatchers will profit greatly by the closest co-operation to reduce losses in getting trains over the road. Long locomotive runs, main trackers, the "peg" and "turn around" plans, are playing a big part in fuel records. The load rating of locomotives offers another and too often neglected field for fuel conservation. Distribution of power offers still another. The distribution question is greatly simplified in the case of locomotives capable of hauling with economy a wide range of traffic.

Water purification is distinctly an aid in operation. It is obviously important to provide proper water for power plants of any kind, particularly those intrusted with the handling of money making traffic. One of the railroads leading in long locomotive runs has given unusual attention to this water problem and has found it possible to reduce by 25 per cent the number of locomotives assigned to traffic involving long runs. It is reported that the largest investment involved in its long runs, is in facilities for improving its waters. The annual saving effected amounts to approximately 75 per cent on the total investment in those facilities. In the matter of increased firebox life the service of its fireboxes has been doubled in less than ten years.

Knowledge of what we are doing

Lack of definite knowledge of the operating possibilities of improved locomotives has done more than any other one thing to retard the progress of the locomotive and the improvement of the locomotive power plant. To be efficient, transportation demands test plant tests for engineering data as the basis of locomotive design and complete road tests for operating data as the basis for financially profitable locomotive operation. The American Railway Association needs a test plant. Every railroad of even fair size needs a dynamometer car more than it needs any other factor in operation. Locomotives have improved not because of exact road operating performance records and facts, but in spite of a lack of them.

Co-operation

Real fuel conservation will be accomplished when and where there is real co-operation, when a very high official compels it. An officer, in position to do so, will ask: "Is our locomotive policy right, our car policy, our maintenance, our yards, our locomotive terminals, our side tracks, our signals and our operation?" Every one of these affects every other one and every one affects fuel. They can be best answered affirmatively by co-operative concentration on one thing—Fuel.

Discussion

In presenting his paper Mr. Basford referred to the performance of the 2-8-4 type locomotive recently built by the Lima Locomotive Works, Inc., and now in service on the Boston & Albany. This locomotive, he said, had recently handled a train of over 9,000 tons in 124 four cars over a 134-mile division with comparatively level grades, except for two pusher grades at an average speed of 18 miles an hour. This run was made with an average rate of combustion of less than 60 lb. of coal per square foot of grate per hour and with an average evaporation of over 8 lb. of water per lb. of coal as fired.

A. W. Perley (O.-W. R.R. & N.) in speaking of the improvement in fuel consumption to be obtained from modern locomotives and other economy devices said that he did not question their value but that the financial problems involved were serious and could not be overlooked. He cited the case of some of the Northwestern railroads where 98½ per cent of all money raised for capital expenditures during recent years had been by the issuance of bonds. Harrington Emerson was inclined to disagree with Mr. Basford's statement that gas velocities are too high. He called attention to the scouring effect of the gases at high speeds which maintains the heating surfaces in a more effective condition for heat transfer than would be the case were the gases to travel at low velocities. He raised the question as to why smaller and thinner tubes

could not be developed with the prospect of more efficient heat transfer.

A. Lipetz (American Locomotive Company) agreed with the principles set down by Mr. Basford. He said, however, that the locomotive has been so far perfected in the last 25 or 30 years that further perfection is possible only in a very small degree and that when we hear of improvements giving 25 or 30 per cent saving in fuel, the comparison is probably made with an obsolete or very imperfect locomotive. Mr. Lipetz classified the overall efficiency of the locomotive as the product of the efficiencies of the boiler, the cylinders and the transmission. He then analyzed the possibilities for improvements in each of these separate efficiencies. He placed normal boiler efficiency of modern locomotives at from 70 to 78 per cent where coal is burned and around 80 per cent where oil is the fuel used, and expressed the opinion that efficiencies much higher than 75 per cent in coal-burning service and 80 per cent in oil-burning service were not likely to be reached, this referring to the internal processes of the boiler itself and not to the possibilities such as that offered by feedwater heating which may be as high as 14 per cent through the reclamation of waste heat. Going to the cylinders, he placed the efficiency of the engine at about 10 per cent, non-condensing, stating that with saturated steam the highest possible efficiency, according to Rankine's cycle, is 15.5 per cent at 30-per cent cut-off; 12.7 per cent at 50-per cent cut-off, and 10.3 per cent at 70-per cent cut-off, which would be slightly higher for superheated steam. On this basis he expressed the opinion that the highest efficiency of the cylinders likely to be obtained with all possible improvements would not be more than 12 per cent with the present reciprocating non-condensing engine. As to the efficiency of transmission, this, he said, is already about 95 per cent, which offers little possibility for further improvement, and his conclusion was that the possible overall efficiency would not exceed 10 per cent, which is a small increase over the efficiencies of locomotives already built of between 8 and 9 per cent.

The important principles through which this improvement may be made, according to Mr. Lipetz, are to keep the cut-off low, to have as uniform draft as possible and the combustion rate as low as possible, the latter requiring the use of large grate areas which practically must be limited to a compromise between the possibilities for economy in operation and the possibilities of high stand-by losses when the engine is not working.

Mr. Lipetz then referred to the Russian Decapod locomotives built during the European war, about 200 of which were placed in operation on various American railroads. These locomotives, he said, employ exactly the features advocated by Mr. Basford, the cylinders being large so that running cut-off would not usually exceed 30 per cent and the engines would slip at a little over 50 per cent, which automatically limited the cut-off to 50 per cent without any actual mechanical limitations. The grate area of 64 sq. ft., he said, was large in proportion to the size of the boiler, although these locomotives were designed for slow speeds on light rails and were, therefore, not mechanically adapted to the heavy service conditions of American railroads. Because of the proportions referred to, however, he said that they have been found to be exceptionally economical in the use of fuel.

Considering the fact that the modern American locomotive has already closely approached the allowable clearance limitations, Mr. Lipetz raised the question as to how the larger cylinders required by the limited cut-off principle were to be incorporated and also how the maximum uniformity of draft so desirable is to be obtained. He expressed the opinion that the three-cylinder locomotive with its cylinder volume divided and its softer and more frequent draft impulses offered the best opportunity to meet these requirements and that, furthermore, the desirability of decreasing dynamic augment is also satisfied by this type.

How can a mechanical officer effect fuel economy?

By John Purcell

Assistant to Vice-President, Atchison, Topeka & Santa Fe

The cost of fuel has more than doubled in the past ten years and has reached a point where it is the greatest item of expense next to wages. The chief mechanical officer is responsible for maintaining the locomotives in an efficient condition at a minimum cost, and with the increased cost of fuel, certain features that have to do with locomotive maintenance effecting fuel economy will require particular attention.

For many years the mechanical officer has maintained his power by doing the work reported by the enginemen and inspectors. Such appurtenances as cylinder packing, valve rings, superheater unit, steam pipe and nozzle stand joints, grates, smoke box air leaks and stopped up flues were not given attention unless the locomotive was reported as not performing properly. The waste of fuel that takes place between the time a locomotive is in first-class condition and the time it is reported not steaming is of considerable consequence. This has resulted in many roads resorting to a monthly inspection of these features in order to reduce the fuel consumption. This inspection and the necessary repairs are usually handled at the time of monthly boiler inspection and, in addition to the fuel saving, this inspection results in decreasing the number of engine failures and in the locomotives giving better service on the road.

Two problems of the mechanical officer

The average life of a locomotive has been approximately 30 years of service, and on some territories the modern locomotive consumes $30,000 worth of fuel per year, or $900,000 worth of fuel in the life of the locomotive. From the trend of fuel costs in previous years, it can be expected that the cost will continue to increase. The chief mechanical officer is confronted with two important problems dealing with fuel conservation, one being to make existing locomotives more efficient, the other to design locomotives which will render efficient service on the territories where the locomotives are to operate.

There is a field for reducing the fuel consumption of existing locomotives by the application of superheaters, feed water heaters, brick arches, increasing steam pressure, improved front end arrangements, elimination of smoke box air leaks, closer fitting grates, and by application of larger tenders which will reduce the number of stops on the road and eliminate taking water at some of the bad water points on the division. These features may be taken care of with a relatively low capital investment and should be given thorough consideration. The useful life of existing locomotives may be prolonged by these additions and betterments, making them useful and efficient units of increased capacity. The service that existing locomotives are to perform in future years should be studied, and where the capital is available, locomotives should be equipped with fuel saving devices of proved merit which will give a net saving for the application. Complications on account of weight distribution on some of the existing locomotives will be found a limiting factor.

The application of devices on new locomotives is less complicated. The locomotives being built each year secure a greater efficiency in the use of fuel. The thermal efficiency of locomotives built in 1900 was approximately five per cent, while locomotives are being built today that have a thermal efficiency of eight per cent. These per cents were secured from test plant results and show an increase in efficiency of 60 per cent in 25 years. Definite progress is being made to reduce the fuel consumption of the locomotive, and developments may be expected in the future that will further improve its efficiency. Experimental work is being done to reduce fuel consumption by use of water tube type of fireboxes, steam pressure as high as 350 lb., three-cylinder construction, 50 per cent cut-off, and the Diesel locomotive.

The need for reliable tests

Any fuel saving or capacity increasing device will make the locomotives more complicated and increase the cost of maintenance, which must be offset by an increase in the economic value of the locomotive. The chief mechanical officer is confronted by claims of low maintenance and high fuel saving for different devices that are startling. Many railroads do not have equipment accurately to test out these devices, with the result that reports of tests are being furnished which are not representative of the net saving that can be realized from the different applications. The American Railway Association is investigating the advisability of having a centralized testing plant for securing accurate and unbiased results for the member roads. Such a plan will be of great assistance to roads not provided with test equipment and organization for handling test work, and will have a far reaching effect in reducing fuel consumption.

Proper maintenance and operation are necessary to secure the greatest net saving on investment from fuel saving or labor saving devices on locomotives. The purpose of these devices is to reduce fuel consumption and without proper maintenance and operation this purpose can be entirely defeated and may result in a fuel loss.

The assignment of power suitable for the service to be performed is an important factor in fuel economy, and is equally important in cost of maintaining locomotives. The grades, average speed, character of business both present and future, quantity of fuel and the available boiler feed water must be considered. A thorough study of these conditions and careful methods of arriving at tonnage ratings of new as well as old locomotives is necessary to assign power intelligently to produce a minimum fuel consumption per unit of work.

A uniform quality of fuel should be furnished over the entire territory to which the locomotive is assigned. Tests should be made to determine the relative consumption per unit of work for each different fuel that is available. The best fuel from the standpoint of consumption and cost should be used. A good quality and grade of fuel is desirable but is not as essential as having a uniform quality of fuel. Good results are being secured from inferior qualities of fuel where it is uniform and the locomotives drafted for that particular fuel.

Better locomotive utilization saves fuel

The utilization of locomotives has been materially increased in the last ten years by the general pooling of power, and in more recent years by extending locomotive runs. It is questionable whether the pooling of power resulted in any fuel saving, but the extended locomotive run over several operating districts, or the quick turnaround on single operating districts without knocking the fire has resulted in fuel saving as well as decrease in maintenance cost. The limiting factors on how far the locomotive can run before requiring roundhouse attention are the design of locomotive, quality of fuel, quality of boiler feed water, character of business and facilities for maintaining the locomotives. It has been found economical and practical to run passenger locomotives from ten to twelve hundred miles without roundhouse attention by having turn-around attention at the end of half of this mileage. Locomotives in through freight service are being operated for distances from three to five hundred miles without roundhouse attention, with an equal measure of economy. This operation eliminates the fuel consumed at intermediate terminals and greatly reduces boiler maintenance costs on account of relieving the boiler of the severe strain caused by expansion and contraction in cooling down and firing up.

While the chief mechanical officer can assist materially in the conservation of fuel by keeping his locomotives in first class condition, the enginemen and firemen can also assist very materially in reducing fuel consumption. I had an opportunity sometime ago to review the performance of 18 passenger locomotives of the same type and size, running in pool service and handling the different trains on a 200-mile division. The report shows the performance of each individual engineman and fireman, as well as each locomotive. The amount of fuel consumed varied, on the same locomotive and same train making the same number of stops, under the same weather conditions, as much as 15 per cent. The best performance was accomplished by the proper operation of the throttle and reverse lever; also lubrication, good firing practices, avoiding waste of steam through pops, and the height the water was carried in the boiler.

It is possible for the best maintained locomotive and the best trained engine crew to show a poor fuel performance if the train is not moved at an economical speed, or if the train furnished by the transportation department does not utilize the capacity of the locomotive. These transportation features are as important in fuel conservation as the design, maintenance, assignment or efficient operation of locomotives, which are the direct duties of the mechanical officer.

Report on boiler feed water heaters

The committee is able to report a very substantial gain in the number of feed water heaters applied and on order as of May 1, compared with previous years as follows:

Year	Feed water heaters	Exhaust steam injectors
1920	7	..
1921	54	..
1922	234	..
1923	1,429	..
1924	2,123	24
1925	2,551	37

This remarkable gain in the past few years is conclusive of the practicability of the feed water heater.

Closed type feed water heater

Since the last report of this committee, important developments for the closed type feed water heater equipment have been three in number as follows:

1—Development of a duplex feed pump of smaller size, but larger capacity and smoother action compared to the original simplex type.

2—Perfection of means for preventing accumulation of scale in the heater.

3—Protection of the heater equipment against any possible corrosion, electrolysis or action of acid used in washing.

The new type of boiler feed pump developed by the Superheater Company with the Elesco closed type feed

water heater is known as the constant flow type. This is of the duplex arrangement wherein steam distribution is so arranged that the movement of the two pistons is the same as if they were connected to cranks set at 90 deg. angles so that with one piston at the end of the stroke, the other is at that instant at mid-stroke, thereby insuring that when one piston is reversing the other is delivering a steady stream of water. Thus a steady regular flow of water is produced, which insures keeping the boiler check off its seat while the pump is in operation.

This pump is capable of discharging 10,000 gallons of water an hour against a pressure of 225 lb. There are now over 300 pumps of this design in service and it has been adopted as standard equipment for the larger sizes of Elesco feed water heaters.

Brief mention was made in the discussion of last year's report to the effect that methods were being developed which would prevent accumulation of scale in the tubes of the closed type feed water heater in bad water districts. It was explained at the time that this process consisted in the addition of a very small amount of a compound to the water in the tender, which acted as a protective colloid and would prevent the precipitation of scale out of the feed water until after it had passed through the heater. The compound used for this purpose is chestnut bark extract, a product commonly used by tanners. This is fed into the water in the tender in proportion of one part extract to about 100,000 parts of water. Tests have shown that some antifoaming compound regularly fed produces the same results.

Experiments have been carried on during the past year in the district where the largest amount of scale accumulated in the tubes of the feed water heaters. It has been found that it is possible to run heaters continuously in that district without cleaning, and without accumulation of any scale or other deposits in the heater tubes. Inasmuch as the most satisfactory results are obtained when the compound is added to the water in the proper proportions, a mechanism has been developed which will automatically measure and feed the compound whenever water is taken. It will normally cost about ¼ cent per 1,000 gallons for treating the water in this way, after the apparatus is applied. It is only recommended that the anti-scale treatment be used in cases where the heater requires washing each 30 days or less.

In certain districts some trouble has been encountered from corrosion from acid washing and electrolysis of feed water heaters, due to some unusual condition in the feed water. In order to prevent all troubles of this nature arrangements are now made to cover all steel or iron parts of the Elesco feed water heater that are touched by water, with a non-corrosive coating. It is the intention of the manufacturers to protect all feed water heaters in this way.

Open type feed water heaters

There have been purchased to date, by the railroads of the North American continent, slightly more than 1,400 open type feed water heaters. Operation of these units has gradually improved through the growing familiarity of the users with the construction and functioning of the apparatus, with the development of organized maintenance and with gradual improvement in materials and construction. The latter have included steps looking to the perfection of the steam valve gear and the water valve service and the selection of suitable materials for gaskets and pump piston and piston rod packings.

The Pennsylvania Railroad has released information concerning tests made on the locomotive testing plant of open type feed water heaters applied to their Decapods or 2-10-0 type locomotives in which they show that within the capacity of the feed water heater they credit a saving of 14 per cent as an average throughout its complete range. This is somewhat higher than has been previously reported by your committee, but this range could well be made with a coal burning locomotive where the coal rate per square foot of grate area is high and consequently reduces the boiler efficiency.

Cleaning of the open type heater, where necessary at all, and in all but the most exceptional cases, can be deferred to the general shopping date. Methods of cleaning, thus far resorted to, consist of scraping, washing, and the judicious use of the scale solvents on removable parts. Fully half of the installations thus far made are characterized by the omission of the oil separator from the exhaust steam line to the heater, this having been done at the option of the users, thus far, with no results that prompt them to question the correctness of this line of procedure.

Scale formation in the heater is confined mostly to the upper section of the heater, where, between shoppings, scale will form to a thickness of between one and two inches. In the lower sections of the heater, the formation of scale is not noticeable. These scale formations in the heater, however, do not affect the working or the temperature of the water delivered. Another troublesome scale formation is found in the atmosphere vent pipe from the heater, which has, at times, been entirely closed by scale, and when in this condition it reduces the temperature of the feed water as much as 15 or 20 deg. on account of the inability to get rid of the air in the heater.

Exhaust steam injectors

In the 1923 and 1924 reports of this committee, brief mention was made of the exhaust steam injector, and attention was drawn to some of its more prominent characteristics. The development of this apparatus to meet American conditions has progressed steadily during the last three years. The principal attention has been given to the perfection of an automatic control arrangement, making unnecessary the manipulation of a number of levers and valves for the proper operation of the instrument. Many of the older types have now been changed and all new ones furnished are equipped with the new control.

As now arranged the operation of this injector is simple and requires little attention on the part of the engineman. To obtain the most economical results it should be operated by adjusting the water regulator so as to meet the demands with the use of as little supplementary steam as possible. The amount of this supplementary live steam when the locomotive is in operation depends largely on the exhaust steam pressure and the temperature of the feed water. The injector has been known to work perfectly against 200 lb. boiler pressure with the supplementary steam shut off entirely when the back pressure was about 4 lb. and the feed water temperature was 45 deg. F. Injectors will handle feed water successfully up to 85 deg. F. temperature.

It is very important that the size of the injector be suited to the size and power of the locomotive.

Some figures are now available in connection with the cost of maintenance of the exhaust injectors. One road reports that the cost of maintenance for twelve months, from April 1, 1924, to April 1, 1925, on eleven injectors amounted to a total of $490. Of this amount $265 was for material and $225 for labor. This amounts to about $45 per injector per year, or $1.20 per 1,000 miles. These eleven engines made a total of 407,245 miles during this period.

The following quotations were selected as typical from various reports received by the committee:

"This device has given us about 5½ per cent reduction in water consumption with a proportionate saving in fuel since its installation in July, 1923. It is my opinion that when the mechanical imperfections we have found in the injector have been eliminated, it will show a saving of between 10 and 11 per cent in fuel."—Report dated April 5, 1925.

"Our experiences with this injector have been so satisfactory that we anticipate a considerable extension in the use of this device. Results of road tests made with very meagre test apparatus showed the exhaust steam injector to save about 7 per cent when compared with a non-lifting live steam injector."—Report dated April 10, 1925.

Inasmuch as such test data now available does not point to any definite conclusions the committee hesitates to give a general statement as to the savings which may be expected of the exhaust steam injector. The lack of determinate data can in part be attributed to the number of variable factors involved such as the use of both exhaust and live steam and to variations in efficiency which may occur at the various rates at which the exhaust injector is operated. It is established, however, that there will be a noticeable drop in back pressure and that the superheat will be lowered about 15 deg.

Feed water purifier

The Canadian National was experimenting with one locomotive equipped with a feed water purifier placed on top of the boiler so that the discharge from the feed water heater and injectors passed through it to the boiler but so much trouble was experienced that it was removed and within the knowledge of the committee there are at this time none in service in this country. This device is particularly applicable to waters which contain a great amount of carbonates and feel that this is a subject that should not be dropped by the American railways.

Feed water heating at terminals

Last year the committee referred to the fact, that approximately 20 per cent of all locomotive fuel is consumed at terminals, and presented some figures to show the effect on fuel consumption of supplying hot filling water for locomotives, where the filling water is heated by blown off water and steam that would otherwise be wasted. It was estimated that the possible fuel saving from this source amounted to from 1,500 to 2,000 pounds of coal for each locomotive filled.

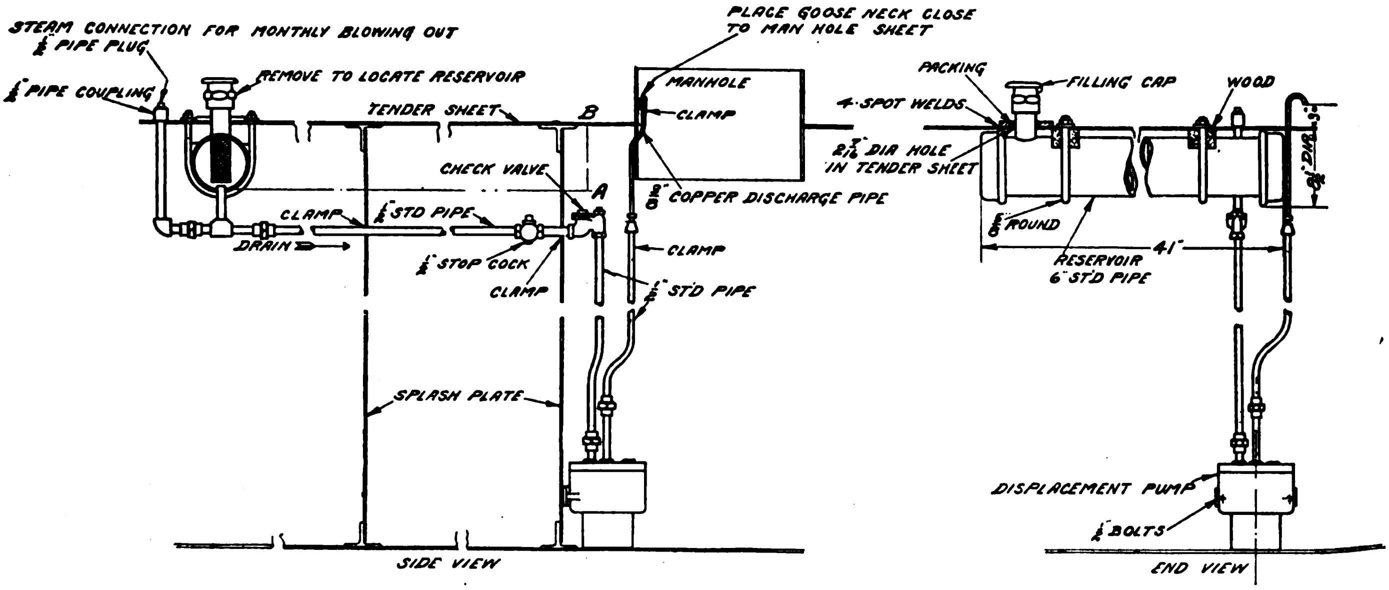
One of the factors in connection with the savings from boiler feed water heating at terminals is found in the reduction of steam blower consumption, resulting from the reduction in time required for firing up locomotives filled with hot water over the time required to fire up a locomotive filled with cold water. The test which will be described in more detail in subsequent paragraphs indicated that this saving in time amounted to about five minutes in the time required to steam up a locomotive for each 10 deg. increase in the temperature at which the boiler was filled. On this basis, it will require about one hour less to steam up a locomotive filled with water at 180 deg. F. than the time required to steam up a locomotive filled with water at 60 deg. F.

As the saving in blower steam consumption resulting from a reduction in the time required to steam up a locomotive depends upon the rate of steam consumption of the blower itself, the committee further undertook to investigate the situation with respect to the quantity of steam required for blower purposes. It is apparent from the replies received, that this phase of locomotive terminal operation has received very little consideration, and that the quantity of live steam ordinarily required for firing up locomotives represents a greater fuel loss than is generally appreciated. While no general conclusion as to steam consumption required for blower purposes can be drawn from the above, it is evident that the blower is a fuel consumer of sufficient magnitude to warrant careful attention.

In this connection some very interesting information was submitted by the Baltimore & Ohio on the use of a motor driven induced draft fan for steaming up locomotives. The following table shows the results of some tests comparing steam blower operation and an electrically operated fan.

These figures show up the cost of operating a steam jet in a very forceful manner. For practically the same conditions throughout, the fan was able to fire up a locomotive for a cost of about 3.7 per cent of the cost when using the steam blower.

The latest important development in connection with boiler feed water heating at locomotive terminals is the direct injection into the locomotive boiler of live steam



Measuring apparatus for automatically supplying cleaning compound to a locomotive feed water heater

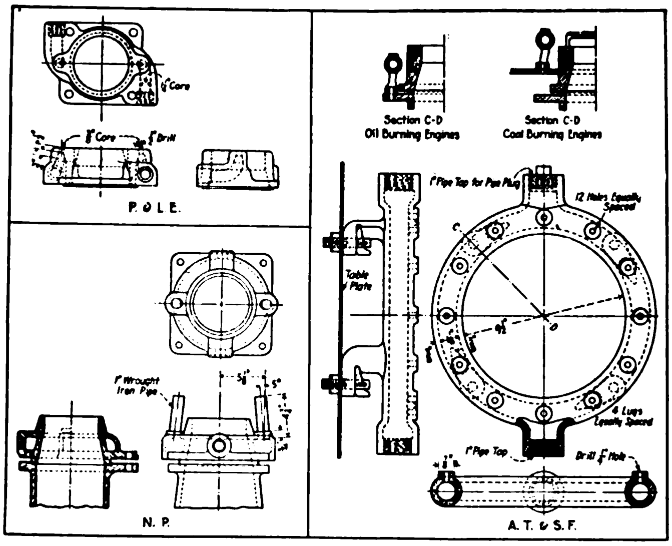
together with hot filling water for the purpose of reducing the time and fuel required to steam up locomotives. This method may also be utilized for steaming up locomotives to a working pressure without lighting the fire, for the purpose of eliminating smoke and blower steam in the engine house. In addition to the economy to be gained from filling with hot water, the direct injection of live steam generated in an efficient stationary boiler requires less fuel than the same amount of steam generated in the locomotive firebox during the firing up period. The reduction in blower steam required with this method represents a further fuel saving.

Data relating to electric blowers for firing up locomotives in enginehouses

Abstract from tests conducted September 26, 1923, on a Mikado locomotive:

Items	Fan	Steam blower	Difference
Kind of coal used	R.m. gas	R.m. gas	....
Kind of kindling used	Fuel oil	Fuel oil	....
Average temperature of water at start, deg. F.	72	76	4
Pounds of coal on grates at start	1,212	1,206	6
Pounds of coal fired during test	690	681	9
Total coal used, pounds	1,902	1,887	15
Draft in smoke box, average, in	0.84	0.81	0.03
Kw. hours used	4.03	......	....
Pressure on steam blower line, lb. per sq. in.	....	85.5	....
Pounds steam used per hour	....	2,452	....
Pounds of steam needed to draft locomotive	....	2,800	....
Area of blower nozzle tip, sq. in	....	0.87	....
Time to get 1 lb. per sq. in. steam pressure after light-off, min	43.0	47.0	4.0
Time to get 65 lb. per sq. in. steam pressure after light-off, min	66.5	68.0	1.5
Cost to draft locomotive	$0.062	$1.682	$1.62
Cost per 1,000 pounds of steam	....	0.60	....
Cost of power per kw.-hr	.0154	......	....

The equipment required for direct steaming is the same as for blowing off locomotives and for washing and filling locomotives with water heated by the blown-off steam and water, with the addition of a live steam main from the power plant with connections to each filling drop. With these connections the usual procedure would be to attach the blow-off valve to the combined blow-off and filling connection as soon as the locomotive is placed in the engine house. If the boiler is to be washed or water changed, the contents are blown off through this flexible connection. When ready to fill, both the filling and live steam valves are opened. The hot filling water and live steam combine in a booster connection and enter the locomotive boiler at a temperature considerably over 212 deg. As soon as water shows in the glass, the hot water valve is closed and the flow of live steam continued until a working steam pressure is built up in the boiler.



Typical examples of locomotive blower nozzles—The P. & L. E. reports that it requires about 16 boiler hp. per hr. to operate the blower shown in steaming up locomotives—The A. T. & S. F. reports steam consumption of about 30 boiler hp. per hr. to operate the blower shown for steaming up oil burning locomotives—The N. P. reports steam consumption of 50 boiler hp. per hr., with the nozzle shown in steaming up coal burning locomotives

This practice was referred to in the previous report in connection with the subject of feed water heating at terminals and several installations of the direct steaming system are now being made at new terminals so that a study of this method in regular operation will be available for the next report. For the current report, the most comprehensive data on this subject is found in the results of a series of tests on steaming up locomotives that was conducted by the Atchison, Topeka & Santa Fe during the past year at Newton, Kansas.

The following general conclusions may be drawn from these tests:

1.—The consideration of steaming up without fire implies the use of high pressure steam in power plants and consequent changes in order to obtain the desired speed in building up the steam pressure in the boiler, requiring the use of steam pressures of about 200 lb. and stationary plants built accordingly; also a system for filling at 180 deg. F. and above.

2.—A saving of fuel would amount to slightly over one gallon of oil, or its equivalent in coal, for each thousand gallons of boiler feed water used in firing up when heated 10 deg. F. by the utilization of waste heat.

3.—There would be an average saving of time of about 4 to 5 min. for each 10 deg. F. difference of feed water temperature.

4.—A saving of time would result from the combined filling, steaming and firing up processes, of 35 min. as compared with simple firing up with 180 deg. F. initial temperature. There should be a reduction of stand-by losses together with some reduction of smoke nuisance in roundhouses. The latter would, of course, be especially noticeable in case of coal burning locomotives.

The report is signed by E. E. Chapman (A. T. & S. F.), chairman; E. A. Averill (Superheater Company), Stanley H. Bray (S. P.), A. G. Hoppe (C. M. & St. P.), V. L. Jones (N. Y., N. H. & H.), John M. Lammedee (Worthington Pump & Machinery Corporation), L. P. Michael (C. & N. W.), Geo. S. Mikles (N. Y., O. & W.), Geo. E. Murray (N. Y. C. & St. L.), L. G. Plant (National Boiler Washing Company), John M. Snodgrass (University of Illinois), and H. W. Sefton (C. C. C. & St. L.).

Discussion

Considerable interest was shown in the steaming up of locomotives at terminals by the injection of live steam directly into the boiler after it has been filled with hot water. The question was raised during the discussion as to what effect this practice would have on expansion in various parts of the boiler, which brought out the explanation that with the injection of steam into the boiler the water is heated gradually throughout the boiler and that steam rises over the entire surface without overheating any part of the boiler. On the contrary when steam is raised from cold water by firing up the locomotive, the firebox is heated to a high temperature while the rest of the boiler is still cold, thus inducing unequal expansion strains.

T. C. McBride (Worthington Pump & Machinery Corporation), said that while the practicability of the locomotive feedwater heater is considered to be established, it should not be thought that development work is not still being done, and called attention to a number of

features in the open type heater which have recently been improved. Mr. McBride also expressed the opinion that the rating of the feedwater heater in terms of per cent of saving does not mean much because the actual saving depends on the amount of work done by the locomotive. He suggested that the reduction in the number of pounds of coal per hour effected by the heater in a given class of service would convey a more accurate idea of its economic importance.

R. M. Osterman (Superheater Company) gave some information concerning the possibilities of the exhaust steam injector from a feedwater heating standpoint which have been brought to light in the development tests of this instrument. He stated that the type of Metcalf injector in use on some foreign roads has effected savings of 3 or 4 per cent as compared with savings of 9 per cent with other types of heaters. He said that the tests in this country indicate no reason why the performance of the injector should be inferior to the pump type heater. The amount of saving, he said, depends on the quality of the injector which in this country has demonstrated its ability to pump against 150 lb. boiler pressure with 1 lb. exhaust steam pressure at 60 deg. superheat. He called attention to the fact that the exhaust steam injector must be carefully proportioned in its capacity to suit the capacity of the boiler which it is to supply with water.

C. W. Sturdevant (Southern Pacific) gave an interesting account of the results obtained on the Southern Pacific by the application of the Zeolite method of water softening on the Southern Pacific. In a stationary boiler plant at Los Angeles, he said, a water is used containing 14 grains per gallon, mostly of calcium and magnesium carbonates. Before using the treatment the feedwater heater would accumulate about 2 in. of scale and the pipes became plugged so quickly that it could not be operated longer than seven to eleven days without cleaning. Since the Zeolite treatment has been in use, the heater was operated six months when, on examination, no trace of scale was found. He said that the treated water had been introduced into locomotive service at Los Angeles and that no trouble with foaming had been experienced, whereas before treatment was introduced it was necessary to use anti-foaming compound on all locomotives as well as in the power plant. In answer to questions, Mr. Sturdevant said that the Zeolite material is a natural green sand, the action of which is essentially to effect an exchange of sodium for calcium. He said that the Los Angeles water would require about 1 lb. of lime and ½ to ⅝ lb. of soda ash per 1,000 gallons, which he estimated would cost about 2¼ cents per 1,000 gallons to treat. The cost of the Zeolite, he said, was about 1¾ cents per 1,000 gallons. The calcium and magnesium removed from the water, he said, are filtered into the sand, which is reconditioned by the periodical introduction of a salt bath at the rate of approximately ½ lb. of salt per grain of hardness per 1,000 gallon of water treated. One advantage of this treatment which he mentioned is the fact that the water can be used for drinking purposes.

Mechanical means for cleaning locomotive flues

By C. B. Smith

Mechanical Engineer, Boston & Maine

The importance of clean metal on both the fire and water surfaces of boiler flues, as well as of firebox plates, needs no argument before the members of this association. The slow accumulation of encrusting solids upon the water surfaces calls for periodic cleaning not less frequently than once a month.

In extremely bad water districts additional means for scale prevention by water treatment are necessary and are practiced by different methods, depending on the chemical nature of the water. In eastern territory water taken by locomotives is usually fit for boiler purposes. Although there are occasional points where relatively bad water must be taken either on the trip or at one terminal, water treatment is not generally regarded as warranted. It is difficult, under such conditions, to show an economy from the investment for boiler compounds. In such territory the gradual accumulation of scale on the water side of boiler plates is certain to occur between class repairs, somewhat reducing the efficiency of heat transmission during the service period of the locomotive. According to Kent, "The influence of scale on heat transmission in locomotive boiler tubes" may vary from 2 to 19 per cent decrease in conductivity. Tests indicate 4 to 6 per cent as representative.

The tubes and flues provide the passage for gases from the furnace and if not kept reasonably free from the accumulation of soot, ash and clinker, to permit sufficient draft for proper combustion, a steam failure will result. Hence the importance of systematic flue cleaning, performed as frequently as the character of the coal requires.

It is not uncommon to dump locomotives for flue cleaning once each week. The cycle of operations include:

Dumping fire.
Removal of required number of firebrick—usually the center rows.
Inspection with an open-flame torch.
Labor of blowing flues and tubes, punching out solid deposits when necessary. Washing with water is also practised by some roads.
Restore firebrick, replacing broken bricks by new bricks—usually 50 per cent of new bricks are required.
Rebuild fire.
Restore steam pressure.

The time required for this cycle of operations is about three hours, including from three-quarters to one hour for cleaning the flues and tubes. In our experience the cost of labor and material involved in this operation amounts to about $30.00 a month for each locomotive.

The writer has no figures on the loss of efficiency due to dirty and plugged flues, but it is obvious that this is cumulative from the time that a locomotive goes into service with clean flues until they are blown out again. Records which have been kept on two divisions show that plugging of flues frequently amounts to 10 per cent of the flue area. This refers to flues completely stopped up, no consideration in the reports being given to flues only more or less coated with soot.

For several years past the installation and satisfactory use of mechanical flue blowers in the rear connection of horizontal return tubular boilers in stationary service has led the writer to a favorable consideration of a similar device for locomotive boilers. Such a device was brought out a few years ago. The blower consists of a movable steam nozzle mounted on each side of the boiler and projecting into the firebox at a point above the arch and at a proper distance back of the tube sheet. To operate it, the nozzle is advanced into the firebox by the movement of a lever and then rotated by a hand wheel. These controlling handles are conveniently located in the cab. The opening in the nozzle is shaped at such an angle that when it is rotated a wide, flat, jet of steam is spread over the tube sheet. When the blowing operation is concluded the nozzle is drawn back into a water space thimble to avoid its being burnt. Steam is piped from the turret or other suitable point on top of the boiler and is preferably controlled by means of a quick-opening valve easily accessible in the cab.

As far as the writer knows the first locomotives in the United States to be equipped with this blower are being operated in New England territory and, as a re-

sult of the experiment, road locomotives built about two years ago were also equipped with it. In this lot were Santa Fe type locomotives having a grate area of 80 sq. ft. and equipped with a Gaines wall and a brick arch. These locomotives have been in constant service running with older locomotives of the same type and design not equipped with flue blowers. If the blowers are operated twice on each road trip, these locomotives do not have to be dumped for flue blowing between the monthly washout periods. On duplicate locomotives not equipped with blowers, it is necessary to dump the locomotives to clean the flues every seven to nine days. At the washout periods when careful attention is given to cleaning flues and tubes, it is found that, regularly there is little cleaning needed on the Santa Fe locomotives equipped with the blowers and they can be made ready for road service more quickly than the locomotives not equipped with blowers.

The other locomotives in this lot were the Pacific type in which it is standard practice to leave an opening between the tube sheet and the brick arch to prevent plugging of the lower rows of tubes by the accumulation of ash and cinders.

The coal used on these locomotives is uniformly low in ash and sulphur, about 36 per cent volatile and 14,000 B.t.u. It has a firm structure and runs about 35 per cent, 1¼-in. slack on the tenders, costing on an average of $5 a ton. The fusibility of the ash varies from 2,650 deg. to 3,000 deg. F.

The maintenance required by this equipment over a two-year period has been found to be very slight. At the monthly boiler washout the apparatus is inspected and the operating mechanism oiled. About once in six months the stuffing box of the blower nozzle tube may need repacking. There has been little or no trouble from the burning of nozzles.

Owing to the good results already obtained with these blowers we have started a monthly program for application of the device at class repairs to a considerable number of Pacific, Consolidation and Mogul type locomotives.

Discussion

This subject aroused much interest among those in attendance. The discussion brought out the fact that the New York, New Haven & Hartford has 43 locomotives equipped with flue blowing devices, and that one of these engines ran 90 days without having the flues blown at the terminal, after which only 17 tubes were found plugged, whereas formerly it was necessary to blow the flues every 10 days. Where engines are equipped with this device, it has been possible to place the arches against the flue sheets of switch engines, thereby reducing the smoke nuisance where this is a factor of importance. In answer to questions it was stated that the fireman is the best judge of the proper locations at which to operate the flue blower. Such locations should be selected where there are few houses and if this is done there will be no complaints because of the soot blown out of the stack. In one case where the flue blower is in use, it has been found by pyrometer readings that the superheated steam temperatures run from 650 to 670 deg. F., whereas 600 deg. F. is the best that can be maintained on other engines.

Other addresses and reports

Other addresses and papers were presented during the convention on the following subjects: Signals and the saving of fuel, by B. J. Schwendt, New York Central; How can railroad management effect fuel economy, by A. R. Ayers, New York, Chicago & St. Louis; How can fuel purchases effect fuel economy, by H. C. Pearce, Chesapeake & Ohio; Stocks, production and consumption of coal, by Mark Kuehn, National Association of Purchasing Agents; The development of oil-burning practice on locomotives, by J. N. Clark, Southern Pacific, and Back pressures as an index to fuel economy, by R. W. Retterer, Cleveland, Cincinnati, Chicago & St. Louis.

The following are the committee reports other than those abstracted herein which were on the program: Report on fuel accounting, distribution and statistics; report on firing practice; report on stationary power plants; report on Diesel locomotives; report on fuel stations. Abstracts of several of these reports will appear later.

Tests of Missouri Pacific three-cylinder Mikado

High boiler and engine efficiencies shown in performance on Altoona test plant

ONE of the three-cylinder locomotives recently built by the American Locomotive Company and described in the *Railway Age,* May 16, 1925, was a Mikado (2-8-2) type for the Missouri Pacific. Before this locomotive was placed in road service it was sent to the testing plant of the Pennsylvania at Altoona, Pa., and submitted to a thorough test. The results obtained are of particular interest due to the fact that this is the first three-cylinder locomotive of which complete tests have been made.

This locomotive weighs 340,000 lb. of which 244,500 lb. is on the drivers, and has a rated tractive force at starting of 65,700 lb., this making the factor of adhesion 3.72. The two outside cylinders are 23 in. by 32 in., the inside cylinder is 23 in. by 28 in., the boiler pressure is 200 lb. and the drivers are 63 in. in diameter. The leading weights and dimensions are given in an accompanying table.

The boiler is of the straight-top type, 88 in. in inside diameter and fitted with a firebox 114⅛ in. long by 84¼ in. wide. There are 199 tubes 2¼ in. in diameter and 45 flues 5½ in. in diameter, all 19 ft. long. The superheater is a type A with 1½-in. tubes, 17 ft. 11¾ in. long. The brick arch is carried on two tubes 3 in. in diameter. The grates are of the table type and the grate area is 66.8 sq. ft. The firebox is fitted with a Nicholson thermic syphon having two water legs. In addition, the barrel of the boiler is fitted with the Harter circulator which consists of a flat horizontal plate located at or about the mid-height of the boiler, extending nearly the full length

of the tubes and provided with steam outlet pipes leading up from the plate to the steam space near the top of the boiler. Coal is fed to the boiler by an Elvin stoker.

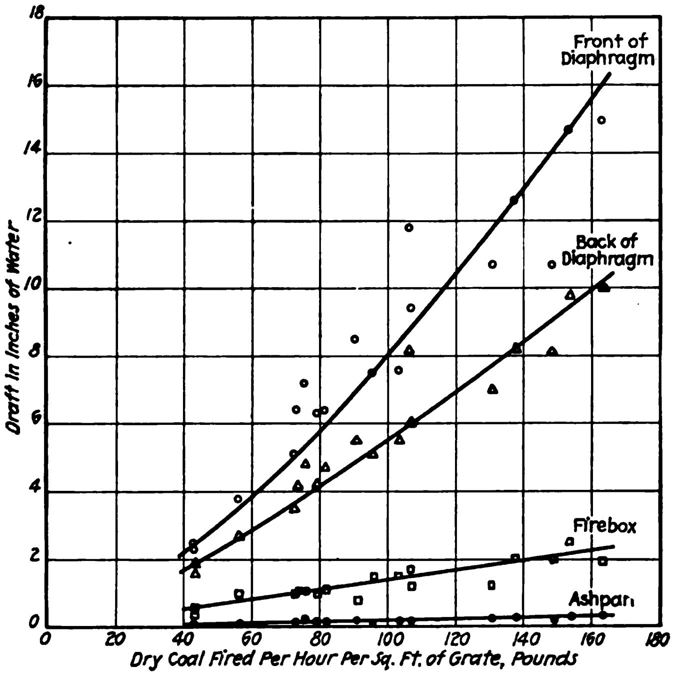


Fig. 1—Draft records for ashpan, firebox and smokebox

The heating and superheating surfaces are divided as shown in the table below:

Heating and superheating surfaces—sq. ft.

	Waterside	Fireside
Firebox, alone	268	271.3
Syphon	67	79.2
Arch tubes	14	15.5
Firebox, total	349	366
Tubes and flues	3,437	3,110
Total evaporative	3,786	3,476
Superheating	1,051	1,367
Comb. evaporative and superheating	4,837	4,843

The water space in the boiler below the second gage cock is 683 cu. ft. and the steam space above is 108 cu. ft. or 14 per cent of the total boiler volume.

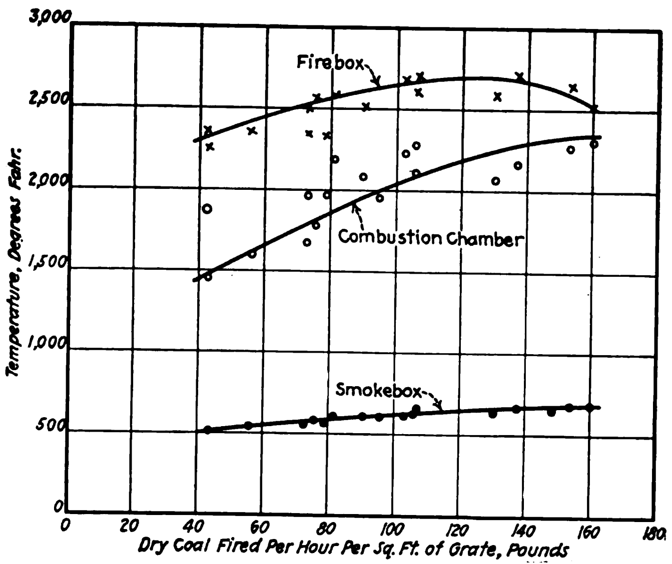

Fig. 2—Gas temperatures in firebox, combustion chamber and smokebox

The total air inlet in the firebox is 28 sq. ft., 26.9 sq. ft. being through the grate and 1.1 sq. ft. above the fire bed. The air openings through the grates constitute 41 per cent of the grate area. The net gas area of the openings through the tubes and flues is 8.5 sq. ft.

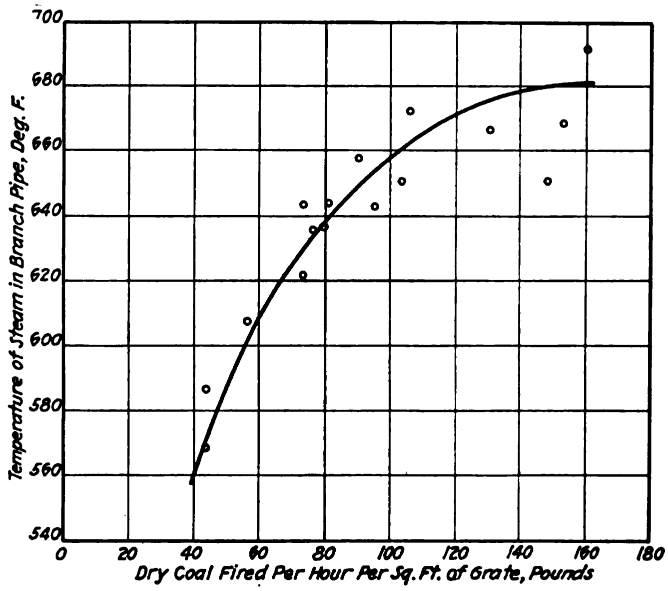

Fig. 3—Temperatures of steam in branch pipe at different rates of combustion

The area of the air inlets to the ashpan is 14.5 sq. ft. or 171 per cent of the area of the tube and flue openings.

The locomotive is equipped with the Baker valve gear

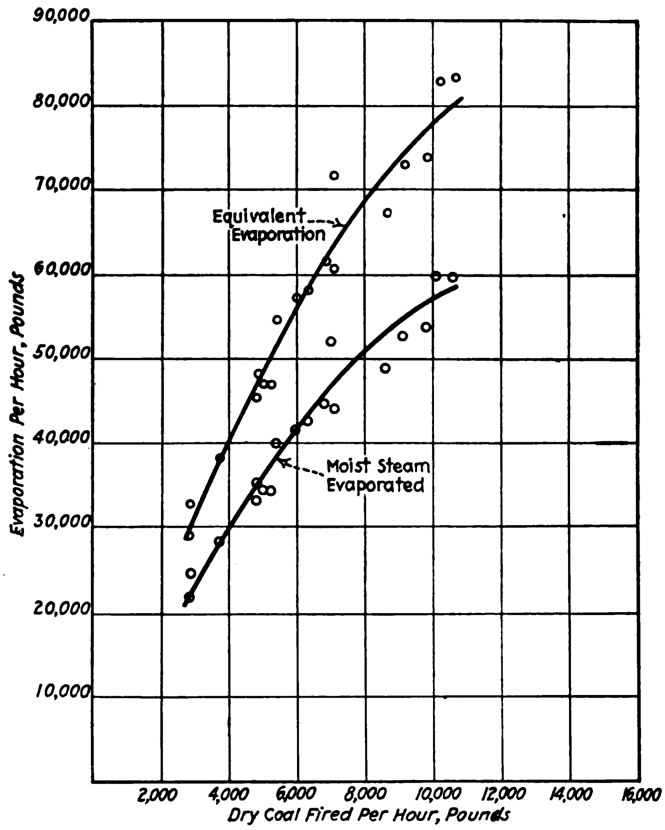

Fig. 4—Actual moist steam evaporated and equivalent evaporation at different rates of firing

and the valve for the inside cylinder is operated by the mechanism employed by the American Locomotive Company for all the three-cylinder locomotives that they have built recently. The piston valves have 6½ in. maxi-

mum travel and are laid out for 1 3/16 in. steam lap and no exhaust lap.

The coal was the same as that generally used at the test plant as a standard for freight locomotive tests and road service. It is a Pennsylvania bituminous coal from the

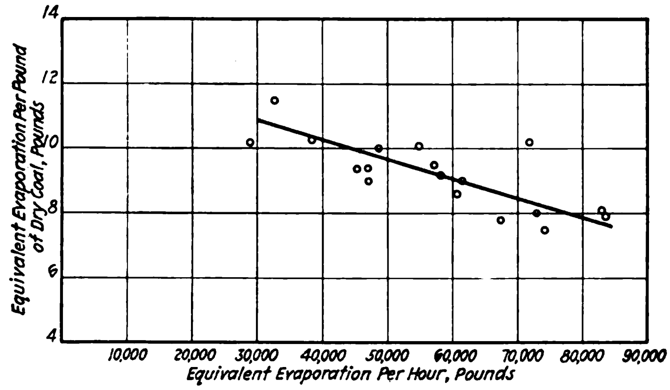

Fig. 5—Variation in equivalent evaporation per pound of dry coal according to boiler output

crows nest mine of the Keystone Coal & Coke Company near Hempfield Station on the main line of the Pennsylvania, in the Greensburg district. It is a Pittsburgh seam coal, medium hard and semi-blocky. The coal contains about 60 per cent carbon and 30 per cent volatile matter and has a calorific value of about 13,300 B.t.u. as fired It was in run of mine size, and, while about 30 per cent of it will not go through a screen having 4-in. round openings, it contains small sizes, so that three per cent of it will go through a screen having 1/16 round openings

When the tests were started, the driving axle bearings

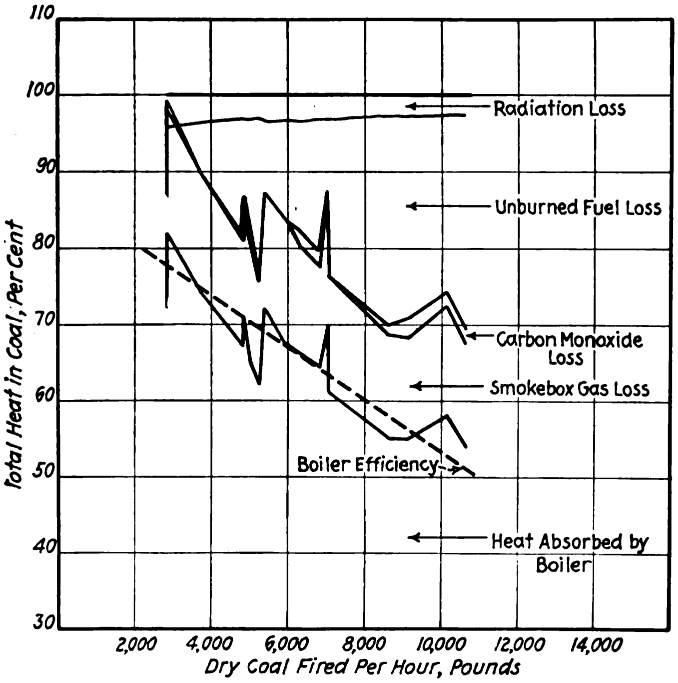

Fig. 6—Boiler efficiency and heat losses

had been run from Schenectady to Altoona but the crank pin bearings had been operated very little. The main crank pin bearings, both outside and inside, are of the floating type in which the brass is in three segments and separated from the rod by a hardened steel liner. The brass bearing is perforated so that the grease has access to both its inner and outer surfaces. On the two outside main crank pins these bearings ran hot until they been well broken in, after which they gave no trouble.

As received at the test plant, the locomotive was difficult to fire and appeared to have insufficient draft. From the similarity to the Pennsylvania Lls. (2-8-2) class it was believed that with proper combustion an evaporation as high as 59,000 lb. of water per hour, or about 12 lb. per square foot of total combined heating surface could be reached. In order to determine this by actual test, a run was made at 160 r.p.m., 50 per cent cut off, and wide

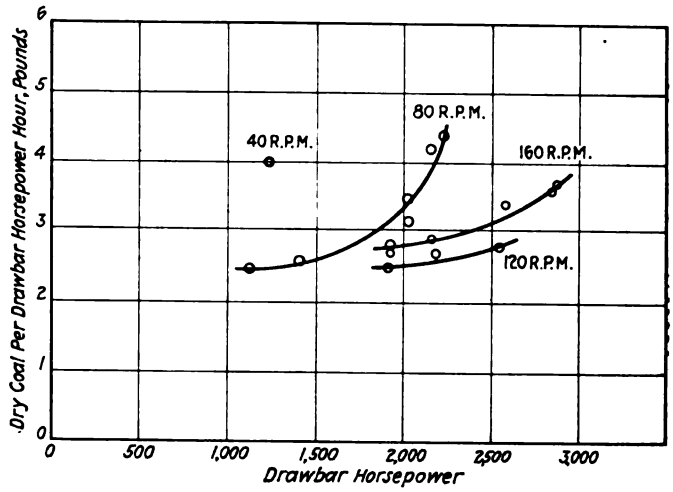

Fig. 7—Dry coal consumption per drawbar horsepower at various speeds and loads

open throttle, as soon as the locomotive had been operated on the plant enough to make such a heavy load feasible. The result was an evaporation of only 48,000 lb. per hour, or about 10 lb. per sq. ft. of total combined heating surface. The draft in the smoke box was 9 in. of water. Measurements of the velocity head of the smokebox gases at the top of the stack showed all positive pressures, and as much as 10 in. or 11 in. of water at the edges.

The stack of the locomotive has a diameter of about

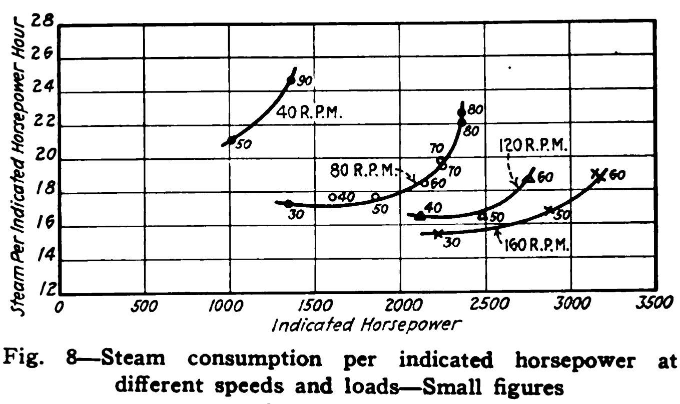

Fig. 8—Steam consumption per indicated horsepower at different speeds and loads—Small figures denote cut-offs

19 in. at the top, tapering to 18 in. near the top of the smokebox, and then tapering out to a much larger diameter at the lower end, which is about 2 ft. 5 in. above the exhaust nozzle.

For the purpose of improving the draft conditions, a basket bridge was fitted to the exhaust nozzle, the inside diameter of the tip was increased to 6½ in. and the stack was fitted with an extension the lower end of which was about 15 in. above the nozzle. Trials with this arrangement showed little improvement in the strength of the draft.

On account of the similarity of the boiler of No. 1699 to that of the Pennsylvania Lls. class, it was thought that the essential features of the Lls. front end, that is, its arrangement of stack and nozzle, might enable No. 1699 to steam properly. The Lls. stack has a diameter of 17 in. at the base and tapers uniformly to the top where the diameter is 24 in., resulting in an area at the top about 50 per cent greater than in the original stack of No. 1699. After this stack, which was found to fit the front end arrangements of this locomotive, had been applied, and with the same 6½-in. exhaust nozzle, with basket bridge,

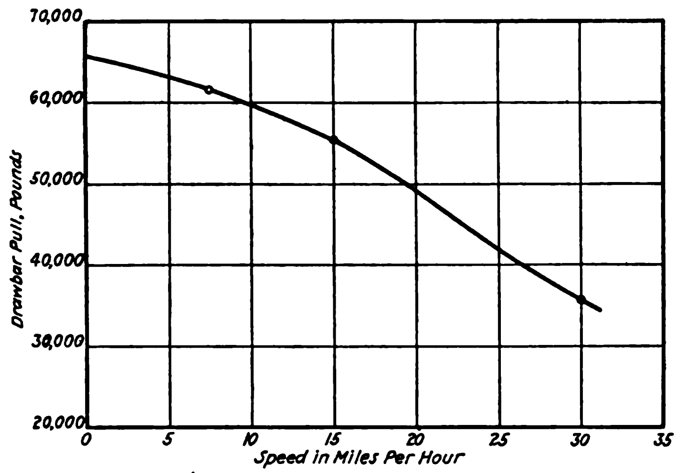

Fig. 9—Drawbar pull at various speeds

a test at 160 r.p.m., 50 per cent cut-off and full throttle showed the limit of the boiler to have been reached at an evaporation of 46,440 lb. per hour. The pressures at the top rim of the stack were small and most of them negative, indicating a vacuum of 4 in. to 7 in. of water, which showed that the stack was not filled. The exhaust nozzle was then increased in diameter to 7 in., retaining the basket bridge, after which an evaporation of 55,000 lb. per hour was obtained.

Notwithstanding the improvements resulting from the changes just described, the firing on heavy load tests was still difficult and the locomotive did not steam freely.

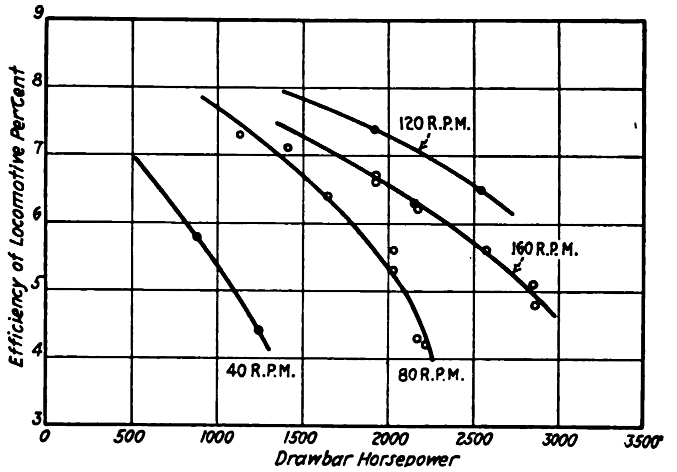

Fig. 10—Overall efficiency of the locomotive at various speeds and loads

Finally, the basket bridge was removed and Goodfellow projections were added to the 7-in. diameter nozzle, and this, with the Lls. stack, was found to make the steaming and draft conditions very satisfactory. It was now found possible to reach an evaporation of 59,900 lb. per hour and later, 61,680 lb. The latter figure corresponds to 12.6 lb. per square foot of heating surface per hour.

Results of tests

A total of 28 runs were made while the locomotive was on the test plant. The duration of the runs was from 15 minutes to two hours, the majority of them being one

hour long. In all but one short run the locomotive was stoker fired. A full throttle was used in all tests. Speeds were 40, 80, 120 and 160 r.p.m., or approximately 7½, 15, 22½ and 30.1 m.p.r. The first six runs were made with the smokebox arrangement as received and with a 6¼-in. exhaust nozzle tip. Changes were then made in smokestack and exhaust nozzles, after which 11 runs were made with the smokestack similar to the Pennsylvania L1s. or 2-8-2 type locomotive and a 7-in. exhaust nozzle with Goodfellow projections. A general summary of the boiler and engine performances as ascertained by typical tests is shown in the accompanying tabulation. In the tables the first group or efficiency tests were with the original smokebox arrangement and the second group or capacity tests were made with the modified smokebox arrangement.

The boiler performance was excellent as its evaporation ranges from 6.7 lb. to 11.1 lb. of water per pound of coal as fired, according to the speed and the amount of coal burned per square foot of great area per hour which ranges from 43.7 lb. to 189.9 lb. The boiler pressure was maintained near its intended pressure of 200 lb. per sq. in. The boiler efficiency at 11.1 lb. of water evaporation per pound of coal was 83 per cent—very good even in stationary service—and was 49 per cent at the time when the boiler was forced to its limit at high speed and at its maximum evaporation of 61,680 lb. or an equivalent evaporation of 84,705 lb. per hour. The superheat in the steam was always near 250 to 280 deg. F, making the total temperature of steam approximately 675 deg. F.—a desirable condition of superheat. All results show the boiler to be well proportioned in firebox, grate area, heating surface and steam space and also in superheating surface.

The engine performance was equally as good. The calculated nominal tractive force is 65,700 lb. and the locomotive developed a drawbar pull of 61,847 lb. at a speed of 7½ miles per hour and 90 per cent cut-off. The maximum power developed was 3,176 hp. which was reached at a speed of 30 miles per hour and 60 per cent cut-off, with an engine efficiency of 90 per cent. The maximum engine efficiency of 94 per cent was reached at a speed of 15 miles per hour and 80 per cent and 90 per cent cut-off, which shows an excellent performance for the locomotive.

Additional information relative to the performance of the boiler and the engine of this three-cylinder locomotive will be obtained by an examination of the accompanying diagrams and typical indicator cards.

In previous tests of two-cylinder locomotives on the testing plant it was found that the fore and aft motion or vibration due to the unbalanced reciprocating parts became so severe at a speed below 200 r.p.m. that additional balance weights were needed in the wheels for test plant operation and it has been customary to add sufficient weights to balance completely all the reciprocating weights. With this three-cylinder locomotive no additional balance weights were applied and a speed of 235

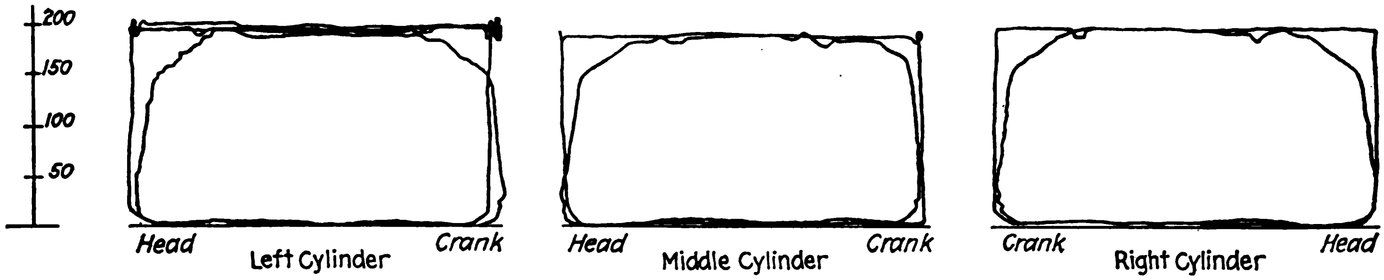

Fig. 11—Typical indicator cards at 7.5 m. p. hr., 90 per cent cut-off and 1,364 indicated horsepower

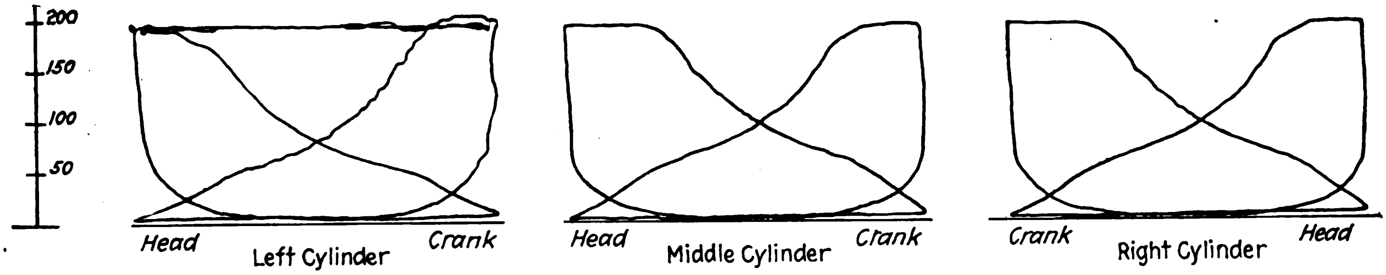

Fig. 12—Typical indicator cards at 15 m. p. hr., 30 per cent cut-off and 1,339 indicated horsepower

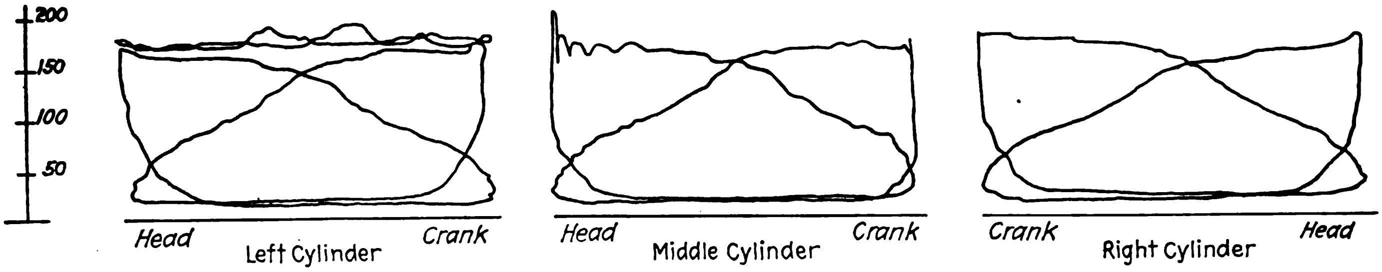

Fig. 13—Typical indicator cards at 30.1 m. p. hr., 60 per cent cut-off and 3,176 indicated horsepower

r.p.m. was reached before the fore and aft vibration became violent enough to endanger the mechanism of the dynamometer. It was the conclusion that without special counterbalancing a two-cylinder locomotive could be operated safely at a speed of 180 r.p.m. and a three-cylinder locomotive at a speed of 240 r.p.m., or at approximately one-third greater speed. At all speeds the drawbar pull lines were more even than those obtained from two-cylinder locomotives.

No measurements were taken of the turning moment or torque for comparison with the usual two-cylinder arrangement.

In conclusion it may be said that with the exception of the front end arrangement the efficiencies of both boiler and engine and the boiler capacity were excellent. This will be evident from a comparison of the results of the tests of this locomotive with those of two cylinder locomotives of comparable dimensions.

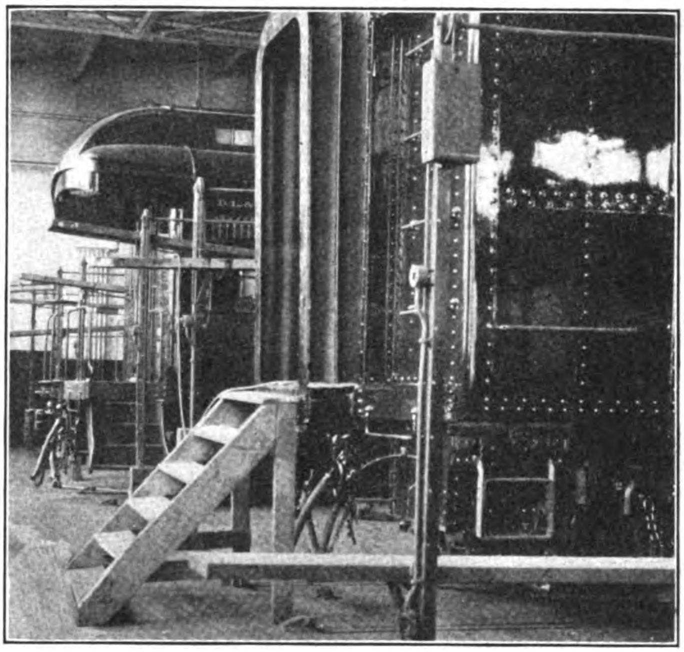
Convenient steps for use in coach repair shops

It is often the case that the most simple arrangement used in a repair shop proves to be a time-saving device of some moment. Such is the case with the flight of wooden steps shown in the illustration which is used in the Kingsland shops of the Delaware, Lackawanna & Western.

It was observed from past experience that it was not



Steps placed for easy entrance into a dining car

unusual to have, in the coach shops, several cars with all the steps removed, or dining cars which have no steps for easy entrance. This condition naturally made it difficult for the workmen to get in and out of these cars and especially difficult to carry in material. As a result, several flights of wooden steps were built just high enough to be level with the vestibule platform of the cars. These steps are placed at the rear of the platform which afford the workmen easy access to the cars. Furthermore, bulky or lengthy materials may be carried into the car without having to make a sharp turn as is the case when using a side entrance.

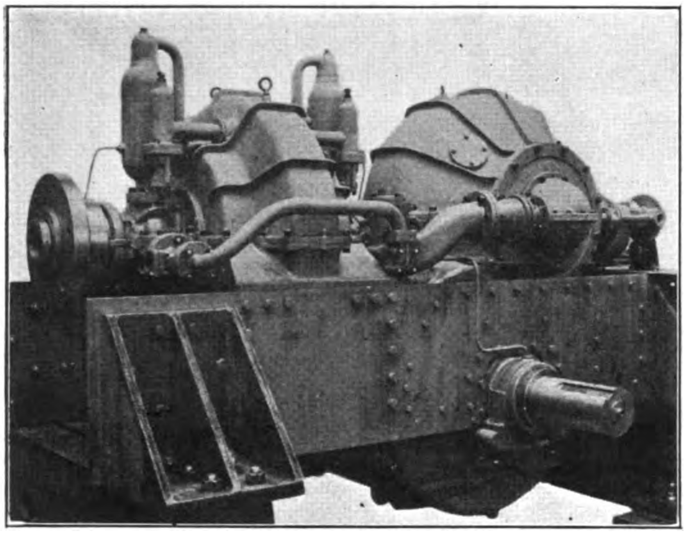
Schneider hydraulic transmission for Diesel locomotives

Combination of mechanical and hydraulic coupling employed—Tests show high efficiency

ALL hydraulic transmissions which up to this time have been developed to the point of application on locomotives or motor cars have operated on what might be termed a full hydraulic coupling principle, the power being transmitted hydraulically and speed regulation obtained by driving and driven pumps in the primary and secondary elements. The applied power is absorbed by the primary element, converted into hydraulic pressure and velocity and then reconverted into mechanical energy in the secondary pump, which acts as a motor, thus transmitting the power to the driven shaft, the speed of which is regulated by varying the delivery volume and pressure of the oil.



Schneider hydraulic transmission completely assembled—This is a 500-hp. equipment

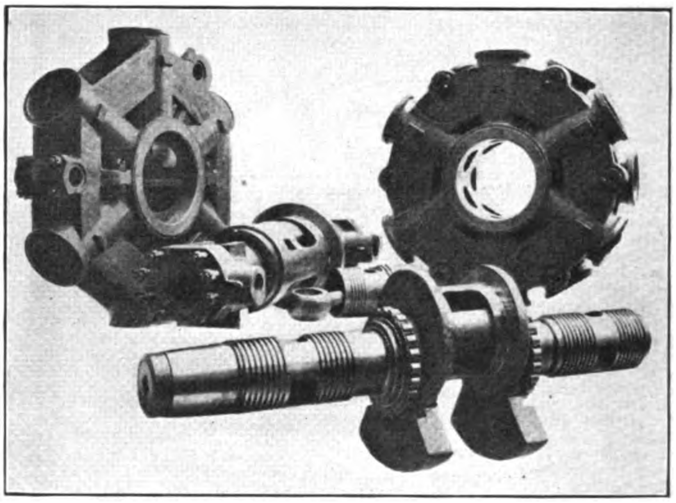
The Swiss Locomotive & Machine Works, Winterthur, Switzerland, is manufacturing a hydraulic transmission which differs materially in principle and construction from the usual type. The patent rights on this development are controlled by Heinrich Schneider, Winterthur, Switzerland, and G. A. Schneider, Montreal, Quebec.

The primary and secondary elements of the Schneider gear, in addition to being hydraulically coupled, are both coupled mechanically to the jack shaft from which the power is transmitted to the driving wheels. With this arrangement a varying portion of the power is transmitted directly to the jack shaft, the rest being hydraulically transmitted through the driving and driven pumps. That portion of the power which is transmitted hydraulically can be regulated from zero to maximum, according to the ratio of transmission, so that at one predetermined speed, hydraulic conversion is entirely eliminated, together with any consequent hydraulic efficiency losses.

Description of the gear

The first gear of this type was produced for use in a 500-hp. Diesel locomotive. The gear, as a whole, is made up of a primary and secondary element, both of which are mechanically coupled through gearing to a jack shaft which drives, through cranks and connecting rods, the driving wheels of the locomotive.

The primary element consists essentially of a hollow crank shaft directly coupled to the Diesel engine crank shaft, a rotor mounted on the shaft and a stationary housing which is attached to the locomotive frames. The crank shaft is a hollow heat-treated steel casting. The offset of the eccentric portion is 2⅜ in. The shaft is designed with a diagonal bridge wall which separates the intake oil end from the discharge end, providing a passage into one end of the hollow shaft, thence through ports on one side of the eccentric portion of the shaft into the rotor cylinders and, on the other side through an opposite set of ports, from the cylinders into the other end of the shaft. The ends of the shaft revolve in labyrinth packings mounted in the gear casing. Above the labyrinth stuffing boxes air domes and relief valves are provided in order to take up shocks and to allow the oil to escape



From left to right—the primary cylinder block, the secondary axle, one of the pistons, the primary shaft and the secondary cylinder block

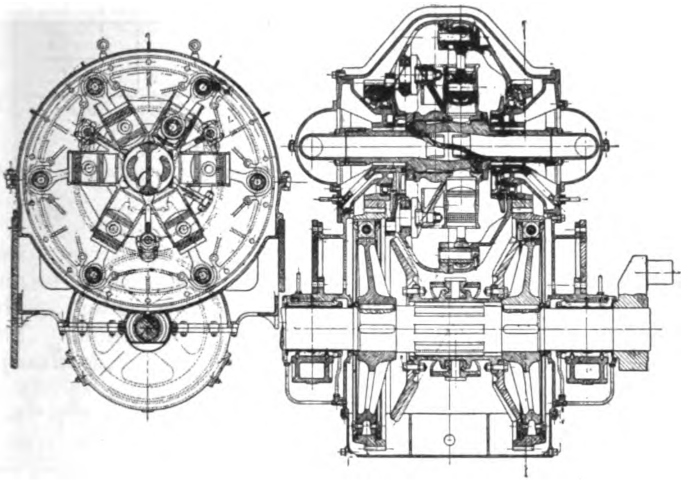
to the outer casing should the pressure exceed a predetermined limit.

The rotor is made up of three elements: the casing, a cylinder block and the pistons which operate in the cylinders. The rotor casing revolves on roller bearings about the axis of the shaft and is also mounted in roller bearings carried in the main casing of the primary element. Mounted on the outside of the rotor casing at each end is a spiral gear ring. These mesh with two corresponding spiral gears keyed to an intermediate shaft, upon which is carried a spiral bevel gear that drives on the jack shaft. Inside of the rotor casing is a cylinder block mounted on the eccentric portion of the primary crank shaft which revolves in the cylinder block on soft metal liquid-tight bearings. The cylinder block contains six cylinders and

is cast in two halves with the cylinders arranged radially in one plane. These cylinders are open at their outer ends to receive the pistons which are secured to the rotor casing by means of connecting rods. The cylinder block in operation moves about within the rotor casing in a circular orbit, the radius of which is equal to the throw of the eccentric portion of the primary crank shaft. To prevent the cylinder block from changing its angular position with respect to the rotor casing, it is secured to the casing by three links which are free to revolve about their bearings in the casing. The length of these links is equal to the throw of the primary crank shaft.

The primary element transmits the mechanical portion of the power input to the jack shaft by means of the bevel gears. Two driven bevel gears are placed on opposite sides of the driving gear. They are mounted on a spline tube which may be moved laterally on the jack shaft in order to throw either one or the other into mesh with the driving gear, thus producing the forward or reverse motion of the jack shaft.

The secondary element is composed essentially of three parts: the shaft, the rotor and the stationary outer casing. The shaft of the secondary element is not a shaft in the true sense of the word, but is, in effect, a stationary hollow axle about which the rotor revolves. Provision is made for its horizontal displacement from the center about which the rotor revolves, on guides attached to the outer stationary casing. This imparts an eccentric motion of variable throw to the cylinder block. To either end of this axle is attached an elbow which is mounted within a telescoping stuffing box. To these boxes the oil pipes are connected. In a similar manner to that of the primary crank shaft, a diagonal bridge wall divides the two ends of this axle into two separate chambers which open through ports at the center to the cylinders of the rotor element. The rotor of the secondary element consists of

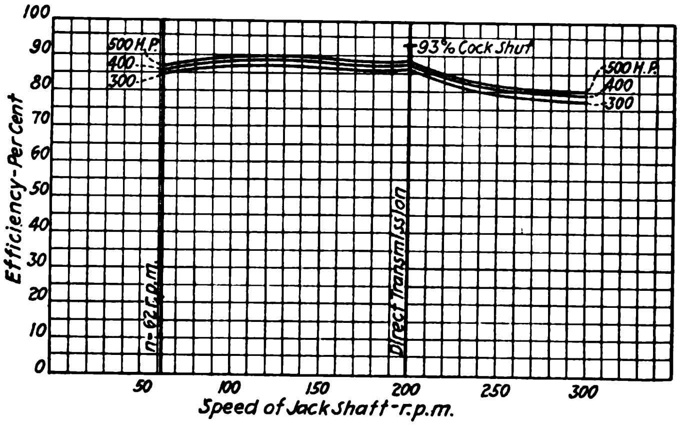


Sections through the primary (left) and secondary (right) elements taken parallel to the axis of the jack shaft

the same essential parts as that of the primary element. At either end of the rotor casing are mounted spiral gear rings which mesh with spiral gears keyed to the jack shaft. The cylinder block contains 12 cylinders arranged in two rows of six cylinders each in parallel planes. The outer ends of these cylinders are open to receive the pistons which are connected to the rotor casing by means of connecting rods. The link connections between the cylinder block and rotary casing of the primary element are replaced in the secondary element by six pin connections on the cylinder block, each of which rotates in a revolving block mounted in the motor casing. The pin bears in a slot extending across the diameter of the revolving block in which it is free to adjust its throw in conformity with the eccentricity of the axle with respect to the center of rotation of the rotor casing.

Method of operation

When the locomotive is at rest, the rotor of the primary element is held stationary by the gearing through which it is mechanically coupled to the jack shaft. The primary crank shaft, however, revolves with the Diesel engine crank shaft to which it is coupled. When the primary crank shaft rotates, it carries the cylinder block with it around its orbit within the rotor casing and the resultant movement of the cylinders over the pistons produces a



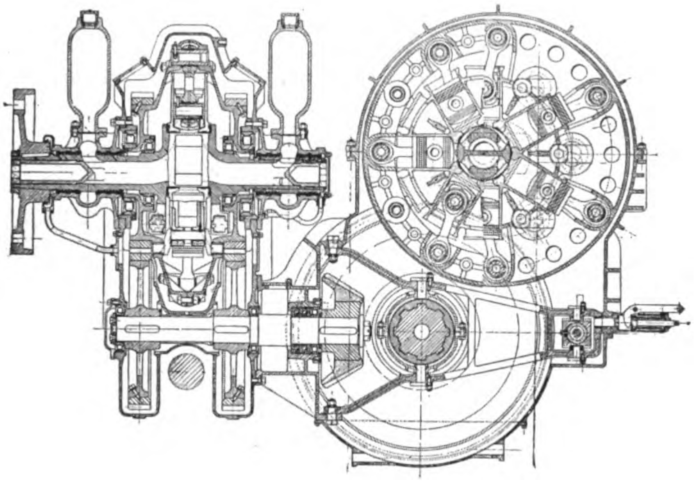
Curves showing the result of efficiency tests of the Schneider hydraulic transmission for constant engine power outputs

suction in three adjacent cylinders and pressure in the opposite three cylinders, thus causing circulation of the oil. The ports in the crank automatically control the admission and discharge of the oil to and from the cylinders.

Control valves are located in the piping connecting the primary and secondary elements and in a primary by-pass connection. In starting the Diesel engine without load and when the locomotive is standing with the prime mover in motion, the by-pass connection is open so that the oil freely circulates from the delivery side directly to the intake side of the primary element and no power is absorbed by the gear. To start the locomotive, hydraulic communication is established between the primary and secondary elements of the gear and the by-pass valve gradually closed, thus effecting a gradual loading of the engine and pick-up in the speed of the locomotive itself.

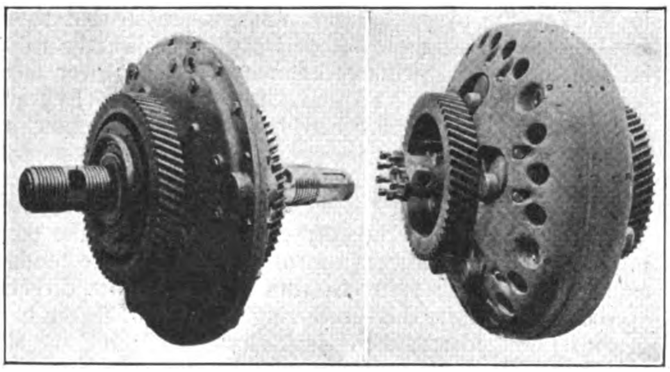
As the by-pass is gradually closed and hydraulic transmission built up, the reaction of the oil pressure tends to cause the primary rotor to rotate in the same direction as the crank shaft, this producing a reaction through the gears tending to rotate the jack shaft. At the same time the hydraulic pressure through the secondary element tends to cause the rotor of this element to revolve and this, through the gear connection, also reacts on the jack shaft. As the jack shaft gradually increases in speed with the engine running at constant speed, the revolutions of the primary rotor also increase in the same direction that the crank shaft is revolving, thus reducing the effective number of revolutions per minute of the crank shaft with respect to the rotor and correspondingly reducing the displacement of oil until a balance is reached when the volume of oil displaced by the primary element is equal to that displaced by the secondary element, the by-pass valve then being completely closed. This speed in the 500-hp. locomotive is 72.5 r.p.m. with the engine developing its full horsepower at 400 r.p.m. of the crank shaft.

To further increase the speed, the eccentricity of the secondary axle must be reduced, thus reducing the volume of oil displacement per revolution of the secondary rotor. Since the eccentricity of the primary crank shaft is fixed, a corresponding reduction in oil displacement is brought about through a further decrease in the relative speed of the crank shaft with respect to the primary rotor which results from an increase in the actual speed of the rotor and a corresponding increase in the speed of the locomo-



Section through the transmission taken at right angles to the jack shaft axis—The primary element is at the left and the secondary at the right

tive. The speed of the locomotive may be increased through this process until the eccentricity of the secondary shaft has been reduced to zero and the displacement of oil also reduced to a zero condition which requires that no further movement of the pistons in the primary element take place. The oil thus becomes, in effect, a solid body which locks the rotor of the primary element to the primary crank shaft, causing the former to revolve with the latter. Under this condition, the entire power of the



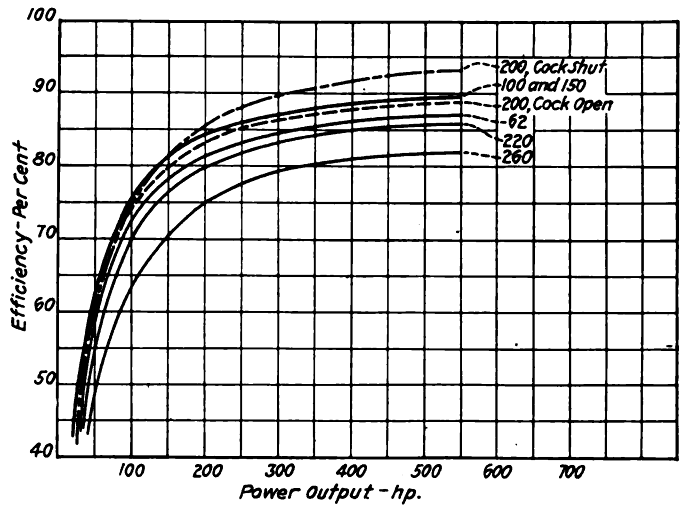
Primary (left) and secondary (right) elements of the Schneider hydraulic transmission

engine is transmitted mechanically from the primary element to the jack shaft, the secondary revolving idly. For the locomotive in question, this condition is reached at a speed of 230 r.p.m. of the crank shaft with full speed of the prime mover.

By referring to the diagram showing the efficiency characteristic of the transmission, it will be seen that for the 500-hp. locomotive the efficiency varies but slightly during the range of speed from starting up to the direct mechanical drive, and that it is slightly under 90 per cent. By closing the valve in the hydraulic connection from the primary to the secondary, thus relieving the secondary of pressure, the efficiency at this speed is increased to 93 per cent. The tests in which the efficiency of the transmission was measured were made with an electric motor driving the primary crank shaft at a maximum speed of 350 r.p.m., which accounts for the low-gear speed of the jack shaft of 62 r.p.m. and a direct drive speed of 200 r.p.m., instead of 72.5 r.p.m. and 230 r.p.m., respectively, for the full engine speed of 400 r.p.m.

By continuing the movement of the secondary axle beyond the neutral point to a negative eccentricity, further increase in speed of the locomotive may be effected. In this case the secondary element becomes the driving pump, taking the power from the jack shaft and transmitting it to the primary element which is caused to rotate in the same direction as its crank shaft, but at a greater speed than the crank shaft.

What takes place fundamentally through the range of operation of the transmission is evident from the torque characteristics of the two elements. The eccentricity of the primary crank shaft being fixed, the oil pressure in the hydraulic system remains constant under all operating conditions, except for sudden changes which may cause momentary increases, which are cushioned by means of



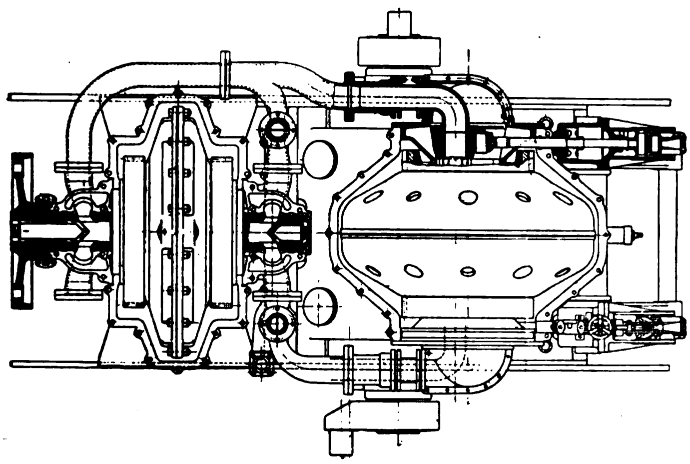
Efficiencies of the transmission for varying power outputs and jack shaft speeds

the air chambers. The constant oil pressure produces a constant torque in the primary rotor equal to the torque of the engine shaft. This torque is always acting on the jack shaft through the primary gear connections. The variation in the jack shaft torque required for the absorption of the full engine horsepower at varying speeds is effected by the secondary element, which delivers a positive torque varying from its maximum at the low speed, to zero at the direct drive and thence becomes negative in varying amount as the speed is increased above that of the direct drive.

The transmission may be reversed in two ways. If the eccentricity of the secondary axles is moved to its full amount on the negative side while the locomotive is standing, on beginning to close the by-pass valve the torque produced by the oil acting on the secondary pistons, is reversed, tending to revolve the jack shaft backwards. This movement, however, starts the primary rotor to revolve backwards on the primary crank shaft, thus increasing the speed of the rotor with respect to the crank shaft, increasing the rate of oil displacement and increasing the power output of the prime mover. This excess of power, of course, reappears at the secondary through the increased hydraulic performance and is in turn taken off the jack shaft through the forward reaction of the

primary gears working against the backward motion of the shaft. Under this condition the lowest speed at which a balance is reached (with the by-pass fully closed) is 195 r.p.m., a speed which reduces the tractive force to about one-third of the maximum at the forward motion low speed.

The other method of reversing the locomotive is to reverse the primary bevel gear drive as well as the eccentricity of the secondary axle. Under these conditions the operating characteristics are exactly the same as for forward motion.



Plan view of the 500-hp. transmission

The eccentricity of the secondary axle is controlled by means of two servo motors arranged in parallel, the operation of which is controlled by a single crank handle in the driver's cab. There are two hand wheels for effecting the hydraulic control. One operates the by-pass cock and another operates the valve by means of which the secondary gear is isolated and relieved of pressure in the case of direct mechanical transmission. The graduation of the stroke of the secondary pistons, the operation of the hydraulic cocks, the reversing of the primary gears and the control of the prime mover are all interlocked with each other so that no false maneuvering is possible.

Description of the Diesel locomotive

At this writing a four-cylinder, two-cycle, 500-b.hp. Diesel engine and the hydraulic gear described above, have been under test for some months at the plant of the Swiss Locomotive & Machine Works, Winterthur, Switzerland. The oil engine and gear have both been designed and tests conducted under the supervision of Heinrich Schneider, chief engineer of the company.

The oil engine employs a solid fuel injection system which does not involve the use of high pressure injection air. Both the oil engine and the gear are to be placed on a trial locomotive for the purpose of making experimental road tests. Some of the more prominent features of this two-cycle solid fuel injection engine consist of a special design of combustion chamber and of the arrangement of ports for the admission of scavenging air and allied control apparatus which allows the engine to be operated at high speed and at high efficiency. As previously described, the Diesel engine will be arranged lengthwise of the locomotive frames, the crank shaft of the engine being connected to the shaft of the primary element in the hydraulic gear by means of a flexible coupling on the engine flywheel. The mechanical transmission system from the engine to the gear is arranged in such a manner that the prime mover revolves in but one direction, all reversing being done within the hydraulic gear. The normal running speed of the engine is 400 r.p.m. and that of the floating shaft in the gear, 230 r.p.m. The estimated weight of the locomotive in working order is approximately 120,000 lb.

Designs have also been made for trial locomotives of 2,000 b.hp.

Report of air brake convention

Association is developing higher standards of maintenance and greater precision in testing

A BRIEF account of the early proceedings of the opening session of the thirty-second annual convention of the Air Brake Association, which was held at the Hotel Alexandria, Los Angeles, Cal., May 26-29, appeared on page 371 of the June issue. Later during the convention the following officers were elected for the year 1925-26: President, R. C. Burns, Pennsylvania; first vice-president, M. S. Belk, Southern; second vice-president, H. A. Clark, Soo Lines; third vice-president, H. L. Sandhas, C. R. R. of N. J.; treasurer, Otto Best, Nathan Manufacturing Company. F. M. Nellis was elected life secretary last year. The executive committee, including the new members, stands: W. W. White, M. C.; William Clegg, C. N.; R. M. Long, P. & L. E.; W. F. Peck, B. & O.; and C. H. Rawlings, D. & R. G. W.

The association voted to hold its 1926 convention at New Orleans, La.

In the following pages will be found abstracts or summaries of the papers, reports and discussions, most of which have an important bearing on the maintenance of air brake equipment.

Report on brake pipe leakage

The committee on brake pipe leakage submitted a progress report in which it summarized the purposes of the committee's investigations as follows: (1) To secure representative data on brake pipe leakage (as distinct from the brake system leakage) as it exists in current train service; (2) to secure data that will show the relation between air leakage from the brake pipe proper and the total leakage from the brake system; (3) to devise means for measuring and recording the total leakage of trains while being operated in regular service; (4) to secure data which will show the ratio of compressed air used for braking purposes and wasted in maintaining leaks; (5) to analyze the data with respect to the effect of leakage on brake operation; (6) to determine what degree of leakage in the brake system can be tolerated without serious interference in the brake action or operation; (7) to analyze the data with respect to cost of the compressed air wasted by leakage; (8) to analyze and compare current methods of inspecting and testing

for brake pipe leaks as well as for methods of repairs and maintenance.

The most important work undertaken by the committee was the development of a means for measuring continuously and recording automatically the total amount of air supplied while operating trains in regular service.

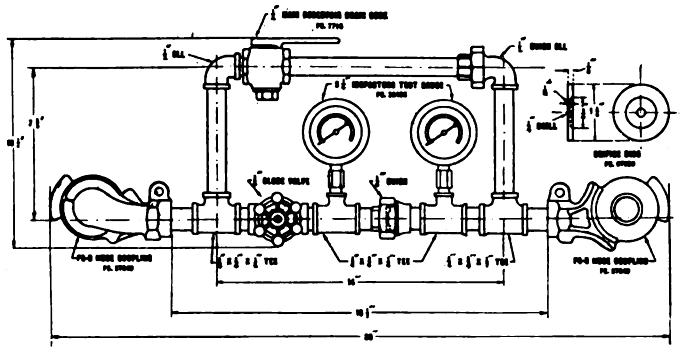
Average cubic feet of free air per car per minute (Brake system leakage) .97
Average cubic feet of free air per car per minute (Brake pipe leakage) .37
Percent increase of brake system over brake pipe leakage 162%

Data which determined the percentage of the brake system to the brake pipe leakage

The report showed in detail the apparatus used for this purpose as well as that employed while making a large number of tests under actual service conditions with train tonnages up to 4,475. The measuring and recording devices were installed in a test car which was piped so that it could be placed in the train directly behind the locomotive tender.

The total number of cars handled during these tests



Brake system leakage testing device

C. M. Kidd (Virginian) president

R. C. Burns (Penna.) first vice-president

M. S. Belk (Southern) second vice-president

H. A. Clark (Soo lines) third vice-president

were 2,768, of which 1,119 cars had 8-in. brake equipments and 1,649 cars had 10-in. equipments, the percentages being 40.5 per cent and 59.5 per cent, respectively. The total number of car-hours covered by these tests was 6,772.3 and 357,195 cu. ft. of free air was used to charge the test trains. Of this amount, 189,563 cu. ft. was consumed in brake pipe leakage. The percentage of brake system leakage in terms of brake pipe leakage was 88.5 per cent, or in other words, the leakage from the volume on the auxiliary reservoir side of the triple valve pistons was 88.5 per cent of the leakage from the brake pipe volume. Assuming that the legitimate use of the brake requires one full service application per car-hour of operation, only 3 per cent of the total amount of air is required to overcome leakage in the average brake system.

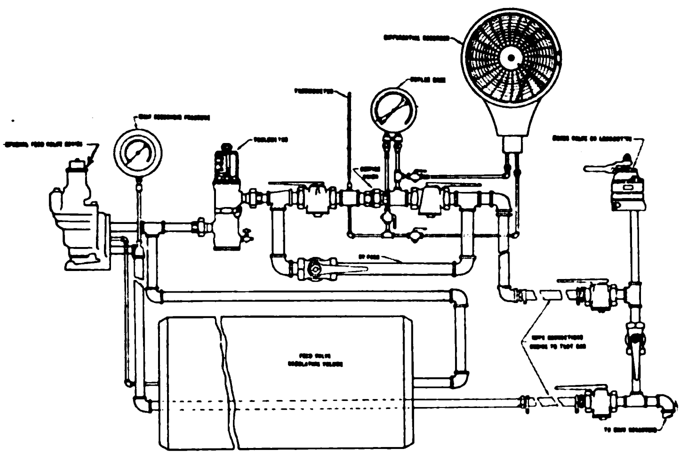
If the locomotive is equipped with the most modern type of air compressor, the amount of steam required to compress the air used per car-hour of operation would be 12.8 lb. For example, a 100-car train operating for 10 hr. would represent on the above basis, a total of 1,000 car-hours and the locomotive would be required to evaporate 12,800 lb. of water in order to supply the compressed air needed, making a total of 1,532 gal. of water. If it is assumed that the efficiency of the locomotive boiler will permit the evaporation of 7 lb. of water, to a pound of coal, 1,000 car-hours will require the burning of 1,830 lb. of coal on the locomotive in order to supply the necessary steam to the air compressor.

Figures compiled from the statistics of a railroad which owns between 900 and 1,000 locomotives show that the total operating freight car-hours during the year 1924 was 89,587,922 for a total of 10,930,392 cars handled. The cost of the compressed air used for the year on the basis of the average rate of air used found in these tests would be $409,864. Taking this on the basis that 97 per cent of the air supplied is wasted, the year's expense chargeable to brake system leakage would be $397,568.

The total number of leaks found on 2,424 cars tested was 10,634. These figures were the result of a questionnaire sent out to members of the association located in Canada and the United States. The total possible leaks on this number of cars that could be reported is 65,448, so that in these tests, leaks were found at 16.33 per cent of all the places tested, a ratio of one leak in every six possibilities. Of the 2,424 cars, 632 had 8-in. brake equipments and 1,792 cars had 10-in. brake equipments. The percentages being 26 per cent and 74 per cent, respectively. Of all the leaks found, 42.5 per cent were of such a nature as to be considered serious.

According to the committee, the most important fact brought out by the running tests was the exceedingly high

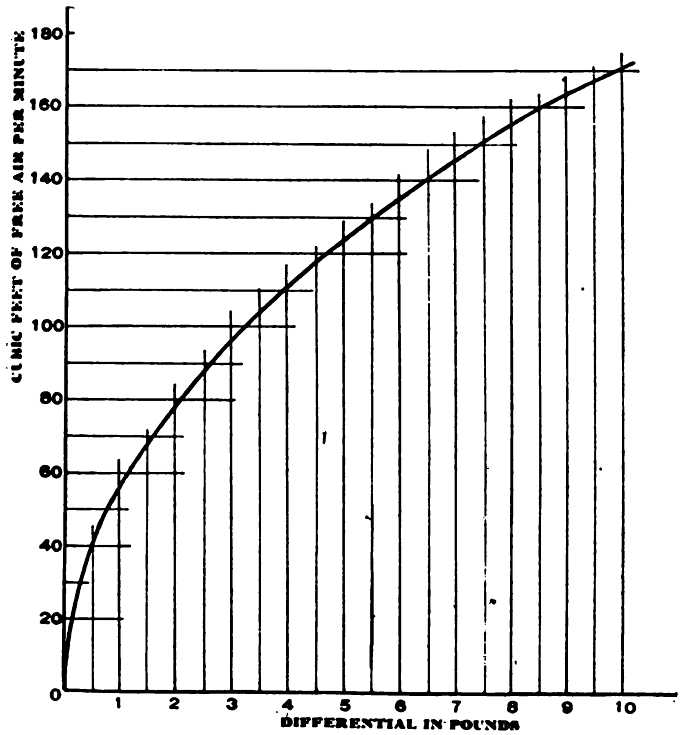
average rate of brake system leakage. The test showed that for the total of 6,772 car-hours of operation, the brake system leakage averaged about 53 cu. ft. per hour for each car or nearly 1 cu. ft. per minute per car. This leakage was made up of brake pipe leakage and auxiliary reservoir volume leakage, the latter being approximately 88 per cent of the brake pipe leakage. If it can be assumed that the running test data secured was representative, the amount of air actually required for brake operations was less than three per cent of the total amount which the compressor supplied to the train.



Measuring and recording apparatus used during running tests

The committee in closing its report, arrived at a number of conclusions, some of which are as follows:

That it is important that regular train inspection should include tests for brake system leakage as well as brake pipe leakage.



Running test—Curve showing relation between difference of pressures on two sides of 27/64 in. orifice and amount of free air used at 60 deg. F.

That a considerable portion of the brake system leaks can be found in the threaded joints of the pipe fittings and air brake equipment devices.

That the tests showed at least 97 per cent of all compressed air used in train operation is wasted by brake system leakage.

That the cost of air wasted and the reduced air brake efficiency due to brake leakage will amply justify a more extensive maintenance program.

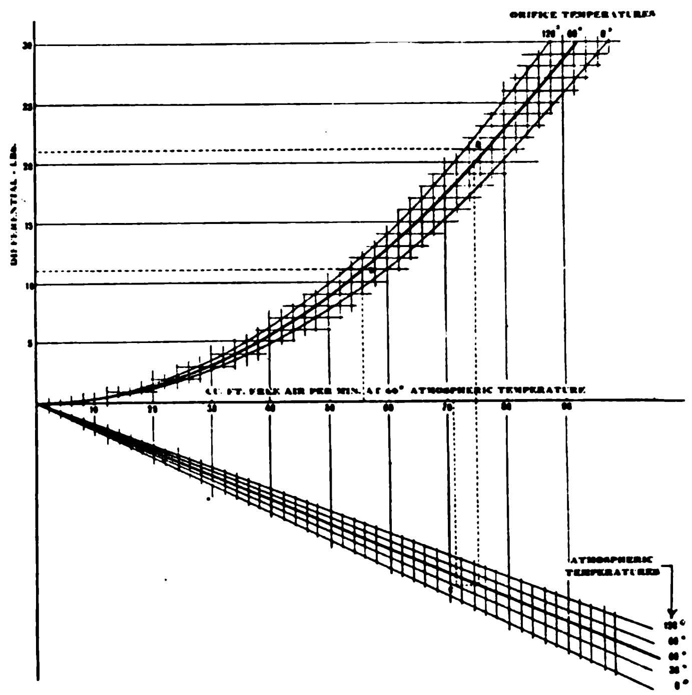
That poor brake equipment installation designs are frequently responsible for difficult brake equipment maintenance.

The committee also recommended that special attention be directed toward brake installation design of existing cars and new cars with a view to making improvements which will make leakage maintenance easier, such as better clamping, elimination of unnecessary pipe joints, reinforcement of pipe threads, etc.

The committee report was signed by C. H. Weaver (New York Central), C. B. Miles (C. C. C. & St. L.), W. W. White (Michigan Central), and R. E. Miller (Westinghouse Air Brake Company).

Discussion

The importance of differentiating between brake pipe and brake cylinder leakage was emphasized, and the necessity of eliminating as far as possible all leaks in the brake system, wherever found. Members of the association corroborated statements contained in the report regarding the wide prevalence of brake system leakage and the resultant heavy expense to the railroads in the way of increased fuel and compressor maintenance costs.



EXAMPLE (WITH TEMPERATURE CORRECTIONS)

Assume 21 lb. differential with orifice temperature 90 deg. F. and atmosphere temperature 30 deg. F.

Start at 21 lb. differential on the vertical scale and pass horizontally to intersect imaginary 90 deg. orifice line at "A." From "A" pass vertically downward to 60 deg. atmospheric line at "B." From "B" pass horizontally to 30 deg. atmospheric line at "C." From "C" pass vertically upward to answer on horizontal scale which is 71.0 cu. ft. of free air per minute.

EXAMPLE (WITHOUT TEMPERATURE CORRECTIONS)

Assume 11 lb. differential when orifice and atmospheric temperatures are 60 deg. F.

Start at 11 lb. differential on the vertical scale and pass horizontally to intersect 60 deg. orifice line at "X." From "X" pass vertically downward to answer on horizontal scale which is 55.5 cu. ft. free air per minute.

Calibration curves for brake system leakage testing device (¼-in. orifice, 70 lb. gage pressure on train side)

One member suggested that couplings be used when possible in place of unions to eliminate an extra joint and another called attention to the angle cock keys as a prolific source of leaks. He stated that many new cocks received from the manufacturers fail to pass the tests, although this is not always due to defective workmanship.

Of 200 such defective cocks, seven were caused by mishandling in shipment and the others passed the test successfully on being heated and the key turned a few times.

Mr. Miles stated in reply to a question, that the committee is not in a position at the present time to recommend definite leakage limits, but believes that the figure will be about 35 cu. ft. per minute.

The members were urgently requested to make the leakage testing device described in the report and after conducting tests on each road, submit as much information as possible on actual conditions. With this representative information at hand, the committee will be in a position to make definite recommendations in its report next year. The committee was continued.

More efficient air compressors

The possibilities of economy through better air compressor maintenance methods were pointed out in this report, which laid particular stress on the advantages of grinding as compared to boring both air and steam cylinders. The grinding of all cylinders at one setting without removing them from the center castings has been made possible by means of a machine now on the market, thereby obtaining the three advantages of smooth, accurate cylinders, reduced labor cost and accurate alinement of the cylinders, the latter a highly important factor in compressor efficiency and prevention of packing troubles. Comparative cost tables included in the report showed a cost of $374.50 for the boring operations on 100 9½-in. compressors as compared to $100 when the cylinders are ground.

The detailed costs of cylinder work on these 9½-in. compressors as well as on 100 11-in. compressors and 600 8½-in. cross compound compressors were as follows:

Cylinder work on 100 9½-in. compressors

Boring operation—			
2 cylinders removed	at	$.525	$52.50
2 cylinders replaced	at	.46	46.00
2 cylinders bored	at	.76	76.00
2 new gaskets at $.65	at	1.30	130.00
10 new cap screws at $.07	at	.70	70.00
		$3.745	$374.50
Grinding operation—			
2 cylinders ground	at	$1.00	$100.00
Saving			$274.50

Cylinder work on 100 11-in. compressors

Boring operation—			
2 cylinders removed	at	$1.34	$134.00
2 cylinders replaced	at	.73	73.00
2 cylinders bored	at	.96	96.00
2 new gaskets at $1.00	at	2.00	200.00
6 new bolts at $.11	at	.66	66.00
		$5.69	$569.00
Grinding operation—			
2 cylinders ground	at	$1.46	$146.00
Saving			$423.00

Cylinder work on 600 8½-in. c.c. compressors

Boring operation—			
2 pair cylinders removed	at	$.91	$546.00
2 pair cylinders replaced	at	.73	438.00
2 pair cylinders bored	at	2.00	1,200.00
2 new gaskets at $2.09	at	4.18	2,508.00
6 new bolts at $.07	at	.42	252.00
		$8.24	$4,944.00
Grinding operation—			
2 pair cylinders ground	at	$2.92	$1,752.00
Saving			$3,192.00

Saving in grinding over boring for one year

9½ in.	$274.50
11 in.	423.00
8½ in.	3,192.00
Total	$3,889.50

The total of this tabulation shows a saving effected for the year of $3,889.50, which represents six per cent interest on an investment of $64,825, or on the performance of the job alone, at the cost of $5,250 for the machine, the investment would be liquidated in 413 days.

Another source of loss of compressor efficiency mentioned in the report is radiation from the exposed top steam heads and backs of steam cylinders, which, on account of being hung low on the brackets, or perhaps located on the front end, present large radiating surfaces. It was recommended that compressor top heads and steam cylinders be jacketed all around.

Information of value regarding grinding wheels and their selection was also included in the report which was read by C. B. Miles, C. C. C. & St. L., representing the Pittsburgh Air Brake Club.

Condemning limits of A. R. A. standard triple valve parts

In accordance with the decision of the association at the Montreal convention, the committee on this subject submitted additional recommendations for consideration. Particular attention was called to the fact that shop facilities, gages, tools, etc., required at the time of repairs to triple valves have not kept pace with the improvements common in well-managed shops largely owing to the gradual though rapid increase in volume of this work. The report indicated that the time has now arrived when air brake shops should be provided with more modern appliances in order that repairs may be made to a uniformly high standard. A somewhat radical departure from previous reports was made through the recommendation of certain gages, tools,* etc., which the committee felt would result in economy when repairing triple valves and reduce the number of failures. Realizing the difficulties and expense involved if each railroad independently set about determining the amount of wear and limiting dimensions that should prevail for each of the component parts of triple valves, the committee went thoroughly into this question in conjunction with the triple valve experts of several railroads and with the manufacturers, and made definite recommendations as to the amount of wear allowable and the limiting dimensions. Tools, gages, appliances, etc., necessary or desirable in order to live up to the recommendations were illustrated in the report.

In order to make the report plain, it was divided into four parts, Division A being a key chart of all triple valve parts, Division B showing the limiting dimensions recommended, Division C explaining more in detail the necessity for following these limitations, and Division D showing drawings of tools and appliances mentioned in the report. This report forms an important addition to the literature on triple valve limits of wear and maintenance methods. The report was signed by R. M. Long, P. & L. E.; W. M. Cavin, A. C. L.; M. S. Belk, Southern, and J. R. McClintock, American Brake Company.

Discussion

There was considerable discussion of this report, which was referred to in highly complimentary terms by several members of the association. L. H. Albers, N. Y. C., called attention to the different problems in general confronting roads in the eastern and western sections of the country, these problems being stuck brakes in the former case and undesired quick action or dynamiting in the latter. He felt that the difficulties of the eastern men would be largely solved by improved standards of maintenance if the condemning limits recommended in the

*Drawings of these gages and tools will appear in subsequent issues of the *Railway Mechanical Engineer.*

report for triple valve parts were lived up to. Mr. Albers questioned the advisability of permitting triple valve bushings to be continued in service with wear up to .012 in. as allowed in the report. He recommended thorough service tests with triple valves worn to the maximum diameter in conjunction with the smallest pistons allowable to determine the rate of build up of brake pipe pressure in releasing, feeling that this is the real answer to the problem of stuck brakes.

The undesired quick action obtained on western roads was generally felt to be caused by extreme temperature variations between mountain and desert country expanding the pistons and rings, with the result that they stick in the bushings. This action is very uncertain and erratic, however, and the western representatives felt strongly that there is not sufficient spread between service and emergency applications and that the only remedy is in a heavier graduating spring. Tests are now being conducted under the auspices of the A.R.A. to determine if a heavier spring can be used to increase this spread without diminishing in any way the safety feature.

The members strongly recommended having triple valves repaired by air brake companies or else in a few centralized shops on each road where the high class work necessitated by the limits established in this report can be properly supervised. No work but cleaning and oiling should be permitted at small car repair points and rip tracks.

The report was accepted and the committee discharged with thanks.

Air brake and air signal piping

This report considered in some detail the relative merits of wrought iron and steel tubing for air brake and air signal pipes, the comparison being strongly in favor of the former. A brief explanation was also given of various methods of protecting the pipe, such as galvanizing, by immersion in a bath of molten zinc; sherardizing, by revolving the pipe in a drum containing a zinc powder resembling cement; electro-galvanizing, by the electroplating process; calorizing, by revolving in a drum containing aluminum powder; and leadizing in which the lead coating is obtained by precipitation from lead solution; electro-plating, hot dipping or a combination of the three. The following disadvantages of these processes were noted in the report:

1.—The coatings are thin and not continuous.

2.—Difficulty in some cases in obtaining any, or a good, coating on the inside of long pieces of small pipe.

3.—Precipitated or electro-deposited coatings are always porous.

4.—Lead, tin or copper are of such an electro-chemical character, with respect to iron or steel, that corrosion of any exposed pipe metal is aggravated, and pitting results. This is a serious matter with pipe threads, that are exposed, and the inevitable breaking of the coating due to the use of pipe wrenches.

5.—The most important disadvantage is the impossibility of bending any of these coated pipes without danger of breaking the coating and exposing portions of the pipe metal to corrosion.

The committee advised that the present recommended practice of the association as to piping be continued upon the following premises:

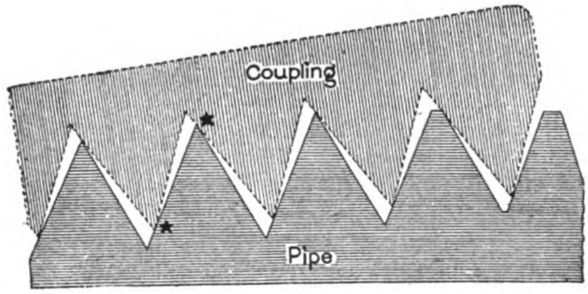
1.—Since the physical characteristics of wrought iron as compared with steel make it much more suitable for use under constant vibration with moisture-laden air, and it is now available in the open market, it should unquestionably be our standard.

2.—As no coating has been developed which will insure protection against corrosion, and at the same time permit of bending pipe, as is essential in air brake work, without danger of rupturing the coating and causing it to flake off and become troublesome in the system, we are opposed to the use of any of these coated pipes.

3.—As the production of wrought iron pipe is small as yet compared with that of steel pipe, the cost of the former must be somewhat greater than that of the latter, but in our judgment it is money well spent, and will be amply repaid in reduced maintenance and much longer life. Furthermore, we do not believe that the additional cost of coated pipes will be repaid in the service rendered by these coatings, while on the other hand, they will unquestionably increase the cost of maintenance.

A proposed change in the recommended practice was also advocated in order to protect against inferior grades of wrought iron. It was suggested that with good wrought iron pipe the standard weight would be sufficient instead of using the extra heavy pipe.

In closing the report the committee called attention to the frequent inconsistency between the threading of pipes and the tapping of sleeve couplings. The recommendation was made that action be taken by the association in order that all fittings for air brake use be tapped on the same tapper as that used for threading the pipes so that contact between the threads will be continuous. Such fittings were said to be available. The committee approved the new "Reinforced" pipe fittings now being introduced for use in railroad service by the air brake manufacturers.



Exaggerated view of fit obtained when a straight-tapped coupling is screwed on a taper-threaded pipe. Stars indicate the only two points of contact between the threads. Tightening the joint mashes the tips of the threads

This report was signed by J. W. Walker, Penna.; W. W. Shriver, B. & O., and F. H. Parke, Westinghouse Air Brake Company.

Discussion

The association was practically unanimous in favor of wrought iron pipe for air brake and air signal piping and voted to adopt as recommended practice the use of uncoated wrought iron pipe made according to A. R. A. or A. S. T. M. specifications for wrought iron. There was a difference of opinion regarding the necessity for using extra heavy pipe on all classes of cars, but most of the members favored its use in connection on locomotive air brake pipes.

A representative of the steel companies stated that all the wrought iron needed can now be obtained on 10 to 20 days delivery and that the reason it is somewhat higher in price than steel pipe results from the fact that it must be hand puddled.

Several members emphasized the necessity of greater care in bending and particularly threading pipe at locomotive and car repair points. Chasers must be kept sharp and compound used to assure smooth, accurately cut threads, the condition of which is an important factor in brake system leakage. The futility of expecting one set of chasers to cut several sizes of threads accurately was pointed out. The use of taper threads on pipe and both male and female pipe fittings was recommended by some of the members.

General News

William H. Johnson, president of the International Association of Machinists, has been re-elected to that office, as appears from the report of the election canvassed at the headquarters of the association in Washington, D. C., on June 1. E. C. Davidson was re-elected secretary-treasurer, and Fred Hewitt editor of the Machinists' Journal.

B. & O. co-operative plan to give shopmen an extra month's work in 1925

Shop employees of the Baltimore & Ohio have earned for themselves about a month's extra work in 1925, according to Vice-president Galloway, as reported in the Baltimore & Ohio Magazine. The plan of co-operation with employees in the shops stipulates that in return for additional endeavor by the employees, the management undertakes to see to it that they are adequately rewarded. This they are trying to do, in the first place, by providing more stable employment. In 1924 heavy improvement work on cars and locomotives, ordinarily not done in the company's own shops, was diverted to them for this purpose. The labor cost on this extra work totaled $347,303. This was not sufficient to provide a full year of 48-hour-week work, but it ameliorated conditions considerably and now, for 1925, the company is planning to do extra work with a labor cost of $2,772,316 in its own shops. This sum amounts to about the same as the average monthly labor expense on maintenance of equipment—hence the statement that the employees are to secure an extra month's work by way of recognition of the benefit to the company of their co-operative efforts.

Up to March 4 the company had received 9,277 suggestions for improvements from employees under the co-operative plan—77.8 per cent of which had been put into effect.

Pennsylvania railroad apprentice school

With the completion of new and enlarged facilities, the scope of the Pennsylvania's apprentice school at Altoona, Pa., has been materially increased, so that approximately 400 apprentices are receiving the benefit of its courses of instruction. The school, which was temporarily discontinued in 1921, was reopened in January of the present year, but was confined to apprentices from the Altoona machine shop only. More room has since been provided by an extension of the building, and in addition to the machine shop boys, the school is now open to regular apprentices from the Juniata shop, the Altoona car shop, the South Altoona foundry, and the Middle Division.

School sessions are held after working hours from 7:00 to 8:30, and 8:30 to 10:00 p. m. on Monday, Tuesday and Wednesday, and from 4:30 to 6:00, 7:00 to 8:30, and 8:30 to 10:00 p. m. on Thursday and Friday, the boys being arranged in sections so that each will be given three hours' school work each week during the period of his apprenticeship. The curriculum provides for mechanical drawing, mathematics and mechanics bearing on shop work, study of materials of construction which deal with the manufacture of iron and steel, and characteristics of different kinds of steel as used in the shop. The courses are adapted for the apprentices in the trades of the different crafts, such as machinists, boilermakers, pipe fitters, and electricians.

Harriman memorial medals to be awarded

The E. H. Harriman Memorial Medals for the best record in accident prevention among American railroads will be awarded this year for the first time since 1916, according to Arthur Williams, president of the American Museum of Safety, New York. In making this announcement Mr. Williams said that analysis of Interstate Commerce Commission statistics indicates that there were fewer casualties among passengers and employees in railroad accidents during 1924 than during any of the preceding nine years. "Mrs. E. H. Harriman has authorized the resumption of the E. H. Harriman Memorial Medals for the year ending December 31, 1924," Mr. Williams said.

The Harriman Gold Medal will be given to the railroad which has the best record for accident prevention and health promotion throughout the system as a whole; a replica in silver will be awarded to the division of the road which has the best individual safety record; and a replica in bronze will be presented to the

Figures as to installations and retirements prepared by Car Service Division, A. R. A., published in Form C. S. 56A-1. Figures cover only those roads reporting to the Car Service Division. Figures of installations and retirements alike include equipment rebuilt to an extent sufficiently so that under the accounting rules it must be retired and entered in the equipment statement as new equipment.

employee who, in the judgment of the road, has been most conspicuous in furthering accident prevention. The awards will be made by the following committee:

R. H. Aishton, President, American Railway Association.
Samuel O. Dunn, Editor, Railway Age.
John Jacob Esch, Interstate Commerce Commissioner.
Julius H. Parmelee, Director, Bureau of Railway Economics.
Arthur Williams, Chairman.

The conditions under which the awards will be made, which were worked out under the direction of Julius Kruttschnitt, include a table of weights providing a penalty fifty times as great for fatal accidents as for non-fatal. Railroads are required to report accidents in and around shops, on boats or wharves, at stations, freight houses, engine houses, coaling stations, water stations, and accidents which occur in connection with construction, repair, painting, and maintenance of equipment, as well as train accidents and train service accidents.

Copies of the conditions of competition and of the forms on which the accident data are to be submitted have been sent to the president of every Class I steam railroad in the United States. The award will be based on the accident experience of railroads during the calendar year of 1924.

Meetings and Conventions

The International Railway Supply Men's Association, during the exhibition held in connection with the International Railway Fuel Association Convention at Hotel Sherman, Chicago, May 26 to 29, elected the following officers: president, Bard Brown, Superheater Company, New York; vice-president, F. S. Wilcoxen, Edna Brass Manufacturing Company, Chicago; treasurer, W. H. Harris of the W. H. Harris Coal Company, Chicago; secretary, F. P. Roesch, Standard Stoker Company, Chicago. Members elected to the executive committee were M. K. Tate, Lima Locomotive Works, Lima, Ohio, L. G. Plant, National Boiler Washing Company, Chicago, W. H. Heckman, Harry Vissering & Co., Chicago, and C. O. Jenista, Barco Manufacturing Company, Chicago.

Great Northern to hold stores convention

The Great Northern held a system convention of stores officers at Superior, Wis., on June 19 and 20. This was the second annual meeting of the system store organization, which was inaugurated last year. Sessions were held in the Hotel Amboy, under the direction of the president, Howard Hayes, general storekeeper, and a general committee. Reports of committees and papers were presented on the following subjects: Scrap handling and reclamation; handling of building and bridge work sheets; developments at the annual meeting of Division VI, A. R. A.; short cuts and methods in store department accounting; handling and storing lumber; fire protection; mechanical appliances; beautifying store grounds; controlling and distributing store stock and the inspection and testing of material.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs.

AIR-BRAKE ASSOCIATION.—F. M Nellis, Room 3014, 165 Broadway, New York City.

AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

AMERICAN RAILWAY ASSOCIATION, DIVISION V.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago.

DIVISION V.—EQUIPMENT PAINTING SECTION.—V. R. Hawthorne, Chicago. Next meeting September, 1925.

DIVISION VI.—PURCHASES AND STORES.—W. J. Farrell, 30 Vesey St., New York.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—G. G. Macina, 11402 Calumet Ave., Chicago. Annual convention September 2-4, Hotel Sherman, Chicago.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Railroad Division. A. F. Steubing, Bradford Corp., 25 West Forty-third Street, New York.

AMERICAN SOCIETY FOR STEEL TREATING.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio. Annual convention week of September 14, 1925, Cleveland, Ohio.

AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago, Ill. Annual meeting October 27 to 30, inclusive, Hotel Sherman, Chicago.

CANADIAN RAILWAY CLUB.—C. R Crook, 129 Charron St., Montreal, Que. Regular meetings second Tuesday in each month, except June, July and August, at Windsor Hotel, Montreal, Que.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 N. Pine Ave., Chicago, Ill. Meeting second Monday in month, except June, July and August, Great Northern Hotel, Chicago, Ill.

CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—R. E. Giger, 721 North 23rd street, E. St. Louis, Ill. Meetings, first Tuesday in month, except June, July and August, at the American Hotel Annex, St. Louis.

CAR FOREMEN'S CLUB OF LOS ANGELES.—J. W. Krause, 514 East Eighth street, Los Angeles, Cal. Meeting second Friday of each month in the Pacific Electric Club Building.

CENTRAL RAILWAY CLUB.—H. D. Vought, 26 Cortlandt Street, New York, N. Y. Regular meetings second Thursday each month, Hotel Statler, Buffalo, N. Y.

CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—A. S. Sternberg, Belt Railway, Clearing Station, Chicago. Annual convention Hotel Sherman, Chicago, September 22-24.

CINCINNATI RAILWAY CLUB.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meetings second Tuesday, February, May, September and November.

CLEVELAND STEAM RAILWAY CLUB.—F. L. Frericks, 14416 Adler Ave., Cleveland, Ohio. Meeting first Monday each month except July, August and September, at Hotel Cleveland, Public Square, Cleveland.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—W. J. Mayer, Michigan Central, 2347 Clark Ave., Detroit, Mich. Next convention, Hotel Winton, Cleveland, Ohio, August 18, 19 and 20.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. B. Hutchinson, 1809 Capitol Ave., Omaha, Neb.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Annual convention September 8-11, Hotel Sherman, Chicago.

MASTER BOILER MAKERS' ASSOCIATION.—Harry D. Vought, 26 Cortlandt St., New York, N. Y.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meeting second Tuesday in month, except June, July, August and September. Copley-Plaza Hotel, Boston, Mass.

NEW YORK RAILROAD CLUB.—H. D. Vought, 26 Cortlandt St., New York. Meeting third Friday each month, except June, July and August at 29 West Thirty-ninth Street, New York.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgreb, 623 Brisbane Building, Buffalo, N. Y. Regular meetings, January, March, May, September and October.

PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Regular meetings second Thursday of each month in San Francisco and Oakland, Cal., alternately.

RAILWAY CLUB OF GREENVILLE.—F. D. Castor, clerk, maintenance of way department, Bessemer & Lake Erie, Greenville, Pa. Meeting last Friday of each month, except June, July and August.

RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Regular meeting fourth Thursday in month, except June, July and August. Fort Pitt Hotel, Pittsburgh, Pa.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings second Friday in each month, except June, July and August.

SOUTHEASTERN CARMEN'S INTERCHANGE ASSOCIATION.—J. E. Rubley, Southern railway shops, Atlanta, Ga.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, 1177 East Ninety-eighth Street, Cleveland, Ohio. Annual meeting September 15-18, 1925, Chicago.

WESTERN RAILWAY CLUB.—Bruce V. Crandall, 189 West Madison Street, Chicago. Regular meetings third Monday in each month, except June, July and August.

*Corrected figure.

Figures as to installations and retirements prepared by Car Service Division A. R. A. Figures cover only those roads reporting to the Car Service Division. They include equipment received from builders and railroad shops. Figures of installations and retirements alike include also equipment rebuilt to an extent sufficiently so that under the accounting rules it must be retired and entered in the equipment statement as new equipment.

Supply Trade Notes

The Forged Steel Wheel Company has moved its office from 170 Broadway to 120 Broadway, New York City.

A. J. Jones, secretary and general manager of the Acme Machine Tool Company, Cincinnati, Ohio, died on May 31.

The Griffin Wheel Company, Chicago, has prepared plans for the construction of an additional plant at Salt Lake City, Utah.

The Hannauer Car Retarder Company, Chicago, has been incorporated to manufacture and sell car retarders and other specialties.

J. M. Davis, president of Manning, Maxwell & Moore, New York, has resigned to become president of the Delaware, Lackawanna & Western.

The Morton Manufacturing Company has appointed the Peden Iron & Steel Company, Houston, Texas, and San Antonio, its southwestern representative.

The Engineering Products Company, Rialto building, San Francisco, Cal., has been appointed Pacific Coast representative of the Clark Car Company, Pittsburgh, Pa.

Emmet K. Conneely, vice-president and manager of sales of the New York Air Brake Company, at New York, has been elected also a member of the board of directors.

The Achuff Railway Supply Company has been incorporated in St. Louis, Mo., to manufacture railway supplies. The incorporators are J. B. Black and W. D. Achuff.

W. C. Miner, general sales manager of the Railway Service & Supply Corporation, has removed his headquarters to Indianapolis, Ind., and the Chicago office has been closed.

Marshall A. Carlton has been appointed Baltimore representative of the Verona Tool Works, Pittsburgh, Pa., with headquarters in the Munsey building, Baltimore, Md.

The Crane Company, Chicago, has acquired property on India street, San Diego, Cal., and contemplates the erection of a factory branch and distributing plant to cost about $80,000.

George T. Willard, representative of the Rail Joint Company, has resigned to become a sales representative of the Railroad Supply Company. His headquarters will be in Chicago.

John A. Zupez has been appointed mechanical engineer of the More-Jones Brass & Metal Company, St. Louis, Mo. Mr. Zupez was formerly in the general mechanical engineer's office of the Missouri Pacific.

E. M. McLean, sales division manager of the Four Wheel Drive Auto Company, Clintonville, Wis., has been promoted to general sales manager. S. H. Sanford, formerly sales division manager, is now assistant sales manager.

Thomas O'Leary, Jr., formerly with the New York Air Brake Company, is now a special representative of the general railroad department, Johns-Manville, Inc., with headquarters at 409 Dooly Block, Salt Lake City, Utah.

Francis W. Pratt, assistant to president of the Goodell-Pratt Company, Greenfield, Mass., has been appointed sales manager to succeed Oscar W. Bardwell, who has resigned as general sales manager but who still remains a director of the company.

Woodson H. Hudson, vice-president of the Georgia Car & Locomotive Company, Atlanta, Ga., died on May 27 in Atlanta at the age of 64. Mr. Hudson for a number of years was connected with the Southern Railway in the motive power department.

The complete line of Garvin tapping machines formerly built by the Garvin Machine Company, New York, has been purchased by the Western Machine Tool Works, Holland, Mich. The Western Machine Tool Works will build a complete line of taper roller bearing equipped tapping machines.

Gunner R. Lundane, formerly manager of the New York office of the Black & Decker Manufacturing Company, has resigned to join the United States Electrical Tool Company, Cincinnati, Ohio, as special eastern representative. He will have his headquarters at the company's office, 50 Church street, New York City.

The New York district sales office of the Consolidated Machine Tool Corporation of America has been removed to 150 Broadway. The Betts Works, Colburn Works and Newton Works of the company are now located at Rochester, N. Y.; the Hilles & Jones Works, at Wilmington, Del., and the Modern Works, at Erie, Pa.

The Locomotive Stoker Company has acquired from the Elvin Mechanical Stoker Company the exclusive patent rights covering the Elvin shovel type stokers heretofore sold by that company, and with their ample facilities for manufacturing stoker equipment for locomotives they are now in a position to supply either the duplex or the shovel type as may be preferred.

The Hammond Brass Works, Hammond, Ind., manufacturers of brass valves and specialties, has placed a contract with the Austin Company, Chicago, for the design and construction of a new foundry and machine shop on Summer street. The new building is to be a 90-ft. by 300-ft. one-story steel structure, containing approximately 30,000 sq. ft. of floor space.

G. H. Webb has been appointed Philadelphia sales manager of the Central Steel Company, Massillon, Ohio. He succeeds A. B. Cooper who died at his home in Philadelphia on May 3. Mr. Webb had been identified with the Central Steel Company for more than eleven years. A branch office of the Central Steel Company has been opened at Los Angeles, Cal.

The Impact Register Company, Inc., Champaign, Ill., of which W. S. Redhed is president and treasurer, H. B. Morrow, vice-president, and L. A. Busch, secretary, has acquired from the Savage Impact Register Company the exclusive rights to manufacture and sell the Savage impact register for the measurement of impact in cars and elsewhere, and Edwin W. Savage has retired from active connection with the sale of this device.

The Safety Car Heating & Lighting Company, New York, has entered into an agreement with the Silica Gel Corporation, Baltimore, Md., for the development under exclusive license, of apparatus for use by railroads and other transportation refrigeration generally. The Safety Car Heating & Lighting Company's engineers, after investigation have decided that the use of Silica Gel for refrigeration is sound and gives promise of extended use.

J. W. Hubbard, of Pittsburgh, Pa., has purchased the controlling interest in the Detroit Seamless Steel Tubes Company, Detroit, Mich., and has been elected chairman of the board of directors. A. A. Templeton, formerly president and general manager, having disposed of his interest in the company, has been succeeded by C. H. Hobbs, who has been vice-president since January, 1922. There will be no other changes in the officers of the company or in the general policies under which it operates.

The Cleveland Punch & Shear Works Company, Cleveland, Ohio, has completed a plant extension program, including the addition of considerable new equipment that will result in an increase of about 50 per cent in its capacity. Robert J. Pardee has been appointed vice-president and works manager, and Arthur Schloz, press engineer. Both were formerly connected with the Toledo Machine & Tool Company, Toledo, Ohio, for about 15 years, Mr. Pardee as assistant to the president and Mr. Schloz as head designer.

J. R. McGinley has been elected chairman of the board of directors of the Duff Manufacturing Company, Pittsburgh, Pa., and is succeeded as president by Thomas A. McGinley. C. N. Thulin has been appointed vice-president in charge of the western sales division, having jurisdiction over the company's main offices and representatives in the middle west, south west, mountain states and Pacific coast. His headquarters, as heretofore, will be in the Peoples Gas building, Chicago. P. G. O'Hara has been appointed vice-president in charge of the eastern sales division which comprises the eastern, central and southern district offices. Mr. O'Hara's headquarters will be at 250 Park avenue, New York City.

The Niles-Bement-Pond Company and the Pratt & Whitney Company, which hitherto maintained joint general sales and accounting departments at New York, have recently moved the sales and accounting departments to the plants. That of the

Niles-Bement-Pond Company is at Hamilton, Ohio, and the Pratt & Whitney Company, at Hartford, Conn. The general executive offices of the two companies remain as formerly at New York; E. L. Leeds, general sales manager, has been appointed vice-president in charge of sales of both companies, with headquarters at New York; Harold F. Welch, New York district sales manager, has been appointed general sales manager of the Niles-Bement-Pond Company, with headquarters at Hamilton; W. P. Kirk, assistant general sales manager of the two companies, has been made general sales manager of the Pratt & Whitney Company; C. K. Seymour, secretary of both companies, is also vice-president, succeeding C. L. Cornell, resigned; Arlo Wilson, special accountant, has been appointed also assistant treasurer to succeed Walter R. Boom, resigned; E. L. Morgan, chief accountant of the Pratt & Whitney Company at New York, has been transferred to the Hartford office; W. L. Burk, Jr., chief accountant of the Niles-Bement-Pond Company, has been transferred from the New York office to Hamilton, and George G. Greist, general manager of the Niles Tool Works, Hamilton, has been made general manager of the Niles-Bement-Pond Company, in charge of the Hamilton office.

Charles A. Starbuck, president of the New York Air Brake Company, died on May 29 at his home in Croton-on-Hudson, N. Y. Mr. Starbuck was born in Niagara County, N. Y., on September 17, 1852, and was educated in the public schools of his native county. He went to New York in 1870 and first worked in the office of a diamond merchant. He afterwards entered the brake business and became vice-president of the Eames Vacuum Brake Company. In 1890 he was elected secretary of the New York Air Brake Company, the successor of the Eames Vacuum Brake Company, the following year he became vice-president and in 1895 was elected president. Under his administration the business of the company expanded to its present large proportions in its field.

C. A. Starbuck

The board of directors of the Standard Tank Car Company has been reconstituted in accordance with a plan of readjustment adopted last February. The board as now constituted consists of: James Andrews, vice-president and general manager; Walter P. Chrysler, chairman of the board of the Maxwell Motor Corporation; William F. Cutler, president of the Southern Wheel Company; Duncan A. Holmes, vice-president of the Chase Securities Company; Stewart McDonald, president of the Moon Motor Car Company; Grayson M. P. Murphy, chairman of the board; J. B. Orr, president; Samuel F. Pryor, chairman of the executive committee, Remington Arms Company; and Ernest Stauffen, Jr., vice-president of the New York Trust Company.

The company's operating organization at Sharon, Pa., has been strengthened by the election of James Andrews as vice-president and general manager, and of Harry Graham as vice-president in charge of sales and operation. Mr. Graham was formerly vice-president in charge of sales of the Illinois Car & Manufacturing Company at Chicago. Substantial progress has been made by the company in the matter of new business and on June 1, the company opened an office at Tulsa, Okla., with F. S. Thompson in charge. In connection with the recent sale by the company of $4,250,000 of National Steel Car Line's equipment trust certificates, the Standard Transit Company was organized to take over the tank line business and the 2,757 tank cars formerly operated by the Tank Car Company, which are leased principally to the large oil companies. The directors of the Standard Tank Car Company will also serve as directors of the Standard Transit Company. The Standard Tank Car Company has an office at Sharon, Pa., and its plant is located at Masury, Ohio, 12 miles from Youngstown.

Trade Publications

Welding and cutting apparatus.—The Alexander Milburn Company, Baltimore, Md., has issued a 26-page brochure descriptive of the Milburn welding and cutting apparatus.

Gears.—Catalogue No. 46, embodying many recent additions to the list of standardized Boston gears, has been issued by the Boston Gear Works, Inc., Norfolk Downs (Quincy), Mass.

Threading machines.—"Thread with Landis" is the title of a 12-page illustrated booklet which has recently been issued by the Landis Machine Company, Waynesboro, Pa., descriptive of Land-Matic die heads.

Yoke riveters.—Bulletin R-205 descriptive of Hanna yoke riveters, which range in sizes from 4 in. to 21 ft. reach and in capacities from 6 tons to 150 tons, has been issued by the Hanna Engineering Works, Chicago.

Cranes.—Bulletin No. 36, illustrating and describing Type V cranes for mounting on motor truck chassis, road wheels, flexible crawling treads or rail wheels, has been issued by the Orton & Steinbrenner Company, Chicago.

Air-tight door.—The American air-tight door for ash pits, boiler settings and other locations where an air-tight door is needed, is described in a four-page folder issued by the Conveyors Corporation of America, Chicago.

Vises.—Catalogue No. 57-B listing discontinued Parker vises and illustrating their substitutes, has been issued by the Charles Parker Company, Meriden, Conn. Line drawings illustrate the various parts of Parker vises, and the names used to designate these parts are given.

Vertical surface grinder.—Complete description and specifications of the Blanchard high power vertical surface grinder are contained in catalogue No. 16, which has just been issued by the Blanchard Machine Company, Cambridge, Mass. The description is paralleled on the left-hand pages, with large illustrations and production data of a variety of work done on the machine.

Packings.—Catalogue A-1925 outlining the features of Garlock service and describing and illustrating its general line of packings—asbestos, rubber, metal and fibrous—gaskets, pump valves, valve discs, etc., has been issued by the Garlock Packing Company, Palmyra, N. Y. Colored illustrations are interspersed throughout the 176 pages of this catalogue, which is attractively bound in black leather.

Arc welding.—A resumé of the uses and value of automatic arc welding, together with a description of the welding apparatus and generating equipment used, is given in Bulletin No. 48937.1 entitled "Automatic Arc Welding," which has recently been issued by the General Electric Company, Schenectady, N. Y. This paper bound booklet contains 20 pages and is well illustrated by photographs of equipment and actual applications.

"Forty years of progress."—This is the title of a 64-page book issued by the Harnischfeger Corporation, Milwaukee, Wis., in which a concise history of its growth and development since its founding forty years ago, and photographs and descriptions of the entire plant and personnel as it is today are given. Each of the various products in the electric crane, hoist, machine tool and gasoline excavator lines, are also illustrated and described.

Brake beams and supports.—A loose-leaf catalogue containing 75, 6-in. by 9-in. pages of mechanical drawings of "Creco" equipment has been issued recently by the Chicago Railway Equipment Company, Chicago. The drawings presented have been selected to show the standards of the various types of brake beams, side bearings and "Creco" third and fourth point brake beam supports and safety devices manufactured by this company. The drawings and information contained in this catalogue are presented in an attractive form and logical sequence, the catalogue being intended as an aid in making satisfactory selections of equipment to meet all requirements and conditions of service. Brake beam repair parts can be ordered by numbers shown on spare part charts or by pattern numbers shown in the main body of the catalogue.

Personal Mention

General

A. O. Gertz has been appointed motive power inspector of the Eastern Pennsylvania division of the Pennsylvania.

D. L. B. Fringer has been appointed motive power inspector of the Central Pennsylvania division of the Pennsylvania.

Henry P. Hass, special assistant to the mechanical manager of the New York, New Haven & Hartford, has been appointed assistant to the mechanical manager. Mr. Hass is a graduate of Sheffield Scientific School, Yale University, of the class of 1907. He began railroad work on July 1, 1907, when he entered the service of the New York, New Haven & Hartford as a special apprentice. Two years later he was appointed material inspector and on December 1, 1911, he became chief material inspector. On February 1, 1916, he was appointed engineer of tests, which position he held until his appointment as office assistant to the mechanical manager on December 1, 1923.

Henry P. Hass

J. H. Reisse has been appointed mechanical inspector of the Chicago, Burlington & Quincy, with headquarters at Chicago.

T. B. Farrington has been transferred to Chicago as assistant general superintendent of motive power of the new Western region.

Frank E. Ballda, assistant to the mechanical manager of the New York, New Haven & Hartford, has been appointed mechanical superintendent, Lines East, with headquarters at Boston, Mass., succeeding B. A. Moriarty. Mr. Ballda began his railroad service as a machinist apprentice with the New York, West Shore & Buffalo (New York Central) in 1885. In November, 1889, he went to the Erie as a machinist and in January, 1890, to the New York, Chicago & St. Louis in the same capacity. Three months later he returned to the West Shore as a machinist and a year later was promoted to foreman. In May, 1896, he went to the Fitchburg as foreman. In 1897 he became a machinist for the New York, New Haven & Hartford, and the following year was promoted to roundhouse foreman. In March, 1904, he became assistant general foreman and in March, 1908, general foreman. In March, 1912, he was promoted to master mechanic and in May, 1915, to superintendent of shops at New Haven. In September, 1918, he became superintendent of shops at Readville, and in August, 1923, assistant to the general mechanical superintendent. In December, 1923, he was appointed assistant to the mechanical manager.

Frank E. Ballda

Frank H. Becherer has been appointed assistant to the mechanical superintendent of the Boston & Maine, with headquarters at Boston, Mass., succeeding Daniel A. Smith, who has been assigned to other duties.

A. C. Davis, formerly assistant chief of motive power—locomotive—has been transferred to Altoona, Pa., as assistant works manager, succeeding T. B. Farrington.

George A. Moriarty, mechanical superintendent of the New York, New Haven & Hartford, at Boston, Mass., has been appointed general mechanical superintendent, with headquarters at New Haven, Conn. Mr. Moriarty began his railroad career in 1887, when he started as a machinist apprentice on the Baltimore & Ohio. In March, 1891, he went to the Pittsburgh, Cincinnati, Chicago & St. Louis (Pennsylvania) as a machinist and served in this capacity subsequently with the Baltimore & Ohio, the Louisville & Nashville, the McNamar Machine Company, the Cincinnati, New Orleans & Texas Pacific, Jeffreys Machine Company, again with the Baltimore & Ohio, the Cleveland, Cincinnati, Chicago & St. Louis and the Columbus Machine Works. In September, 1895, he returned to the Baltimore & Ohio as machine shop foreman. In September, 1898, he again left that railroad, returning in July, 1899, as assistant roundhouse foreman. In February, 1901, he was promoted to roundhouse foreman and continued in that capacity until June, 1903, when he went to the Erie in a similar capacity. In 1904, he was promoted to general foreman and in October, 1906, to master mechanic. In 1907, he went to the New York, New Haven & Hartford as master mechanic, was promoted in January, 1917, to general master mechanic, Eastern grand division, and four months later to mechanical superintendent, Lines East.

G. A. Moriarty

William L. Bean, assistant mechanical manager of the New York, New Haven & Hartford, with headquarters at New Haven, Conn., has been promoted to mechanical manager with the same headquarters, succeeding L. M. Reed, resigned. Mr. Bean was born on January 3, 1878, and was graduated from the University of Minnesota in 1902, having completed a course in mechanical engineering. He immediately entered the service of the Northern Pacific as a special apprentice, and served in that capacity until late in 1904. On January 1, 1905, he became gang foreman of the Atchison, Topeka & Santa Fe. The following year he was promoted to inspector, and in 1908 to machine shop foreman. In 1909 he became division foreman, and a few months later, motive power assistant. In 1911, he was appointed bonus supervisor and held that position until early in 1912. He then entered the service of the Oxweld Railroad Service Company as chief engineer, remaining with that company until 1916. Mr. Bean went with the New Haven in July, 1916, and in September, 1917, was made assistant general mechanical superintendent, and on November 1, 1918, mechanical assistant to the president, acting in that capacity until December 1, 1923, at which time he was made assistant mechanical manager. His final work was that of assisting the president in his investigation of the property and in

W. L. Bean

formulating a report and recommendations in accordance with which a program for the improvement of the property was undertaken. Mr. Bean in particular covered matters relating to mechanical department facilities, new power, etc. Subsequently it has been largely in accordance with his recommendations and plans that the very large number of improvements for affording the mechanical department better facilities have been carried out and the large purchases of new locomotives have been made.

KENNETH CARTWRIGHT has been appointed assistant mechanical engineer in charge of specifications, designs, records and standards of equipment of the New York, New Haven & Hartford. Mr. Cartwright was graduated from the Massachusetts Institute of Technology as a mechanical engineer in 1912. He began his railroad career as a material inspector for the New Haven in June, 1914. In June, 1918, he left the railroad to become a junior lieutenant in the Navy. He returned to the railroad in February, 1920, as assistant to the engineer of tests and general mechanical inspector. On May 16, 1924, he was appointed chief mechanical inspector, which position he held until his recent appointment.

Pennsylvania combines two regions

On June 1 the operations of the Pennsylvania in the Northwestern and Southwestern regions of the system were combined for the purpose of obtaining the advantages of a more concentrated administration of the service and the facilities in the territory affected. The consolidated region is known as the Western region.

R. G. BENNETT, who recently was appointed general superintendent of motive power, Southwestern region, is now general superintendent of motive power, Eastern region, with headquarters at Philadelphia, Pa.

J. M. HENRY has been appointed assistant chief of motive power —locomotives—on the staff of the chief of motive power of the Pennsylvania system. Mr. Henry was born on October 10, 1873, at Altoona, Pa. He entered the service of the Pennsylvania as a special apprentice in the Altoona machine shops in May, 1889, and served as an apprentice until September 1, 1896, when he entered Purdue University, being furloughed from the shops during the school term each year. He was graduated in June, 1900, and then became a special apprentice in the office of the assistant engineer of motive power at Altoona. A year later he was promoted to motive power inspector at Altoona, and in February, 1902, became assistant engineer of motive power of the Erie division and Northern Central Railway at Williamsport, Pa. From July 1, 1903, to December, 1913, he was master mechanic at various shops. On the latter date he was promoted to superintendent of motive power of the Western Pennsylvania division, and on May 1, 1916, was transferred to the operating department as assistant superintendent of the Pittsburgh division. In April, 1917, he was transferred to the New York division, and in October of the same year he was appointed assistant general superintendent of motive power at Altoona. On March 1, 1920, he was appointed one of the four regional general superintendents of motive power, which position he held until his recent promotion.

J. M. Henry

F. L. CARSON, mechanical superintendent of the San Antonio & Aransas Pass, has been promoted to assistant superintendent motive power and equipment of the Southern Pacific, lines in Texas, with headquarters at Yoakum, Tex. Mr. Carson was born on February 23, 1871, at Oakland, Cal. He entered railway service in 1890 as an apprentice in the mechanical department of the Atchison, Topeka & Santa Fe and was promoted to erecting foreman in 1895. He was promoted to roundhouse foreman in 1897 and to general foreman at Cleburne, Tex., in 1900. Mr. Carson was promoted to master mechanic of the Northern division in 1901, where he remained until 1905, when he was appointed master mechanic of the El Paso & Southwestern, now a part of the Southern Pacific. Two years later he was appointed master mechanic of the Mexican Central, where he remained until 1909, when he resigned to become superintendent of machinery of a mining company. Mr. Carson returned to railway service in 1912 as master mechanic of the Chicago Great Western. Later in that year he was appointed master mechanic of the San Antonio & Aransas Pass, with headquarters at Yoakum, Tex., in which position he remained until November, 1914, when he was promoted to superintendent of motive power. His recent appointment as assistant superintendent of motive power and equipment of the Southern Pacific, lines in Texas, is the result of the consolidation of the San Antonio & Aransas Pass with the Southern Pacific lines.

A. MCDONALD has been appointed acting superintendent of motive power of the shops of the Canadian National at Montreal, Que., succeeding G. M. Wilson, who has been assigned to other duties.

J. T. CARROLL, general superintendent motive power of the Baltimore & Ohio at Baltimore, Md., has been appointed general superintendent motive power and equipment, with the same headquarters.

Car Department

R. PRICE has been appointed car foreman of the Black Hills division of the Chicago & Northwestern, with headquarters at Chadron, Neb., succeeding E. R. Phillips.

J. J. TATUM, superintendent car department of the Baltimore & Ohio at Baltimore, Md., has been appointed general superintendent car department, with the same headquarters.

Master Mechanics and Road Foremen

JOHN T. GROW has been appointed district master car builder of the New York Central, with headquarters at Albany, N. Y., succeeding G. E. Carson, retired. Mr. Grow was born on March 30, 1887, at Buffalo, N. Y., and was later graduated from the Masten Park High School, Buffalo, N. Y. He entered railway service on September 6, 1904, as a laborer in the planing mill of the East Buffalo Car Shops of the New York Central. In 1907, he was promoted to mechanic, and in 1908, to piecework inspector. He became foreman at Corning, N. Y., in 1912, and held this position until 1915, when he was transferred as foreman to Clearfield, Pa. From 1917 to 1923, he was assistant shop superintendent at Avis, Pa., and at that time became assistant district master car builder at Albany, N. Y., which position he held at the time of his recent appointment.

John T. Grow

J. E. FRELS, master mechanic of the San Antonio & Aransas Pass, at Yoakum, Tex., has been appointed master mechanic of the Southern Pacific, with the same headquarters.

E. R. PHILLIPS has been appointed general car foreman of the Iowa division of the Chicago & Northwestern, with headquarters at Council Bluffs, Iowa, succeeding H. W. Hanson.

P. L. LAIRD has been appointed general car foreman of the Madison division of the Chicago & Northwestern, with headquarters at New Butler, Wis., succeeding H. Bentson.

W. H. STEMPLE has been appointed general car foreman of the Iowa and Minnesota division of the Chicago & Northwestern, with headquarters at Belle Plaine, Iowa, succeeding R. Price.

H. BENTSON has been appointed general car foreman of the

Wisconsin division of the Chicago & Northwestern, with headquarters at (Chase Yards) Allis, Wis., succeeding J. C. Byrne.

H. W. Hanson has been appointed district master car builder of the Iowa and Minnesota, Northern Iowa and Sioux City divisions of the Chicago & Northwestern, with headquarters at Boone, Iowa.

C. C. Nash has been appointed district master car builder of the Madison, Minnesota and Dakota divisions of the Chicago & Northwestern, with headquarters at Winona, Minn., succeeding H. Marsh.

J. W. Dunning has been promoted to general foreman car repairs of the Southern, with headquarters at Columbia, S. C. It was incorrectly stated in the May issue of the *Railway Mechanical Engineer,* under the shop and enginehouse personals, that G. W. Dunning had been promoted to general foreman of the Southern.

Shop and Enginehouse

C. H. Hartland has been appointed assistant foreman of the boiler shop of the Pennsylvania, with headquarters at Renovo, Pa.

A. C. Reeves, erecting shop foreman of the West locomotive shops of the St. Louis-San Francisco at Springfield, Mo., has been promoted to general foreman, succeeding H. J. Ray.

E. L. Iotte, night roundhouse foreman of the Chicago, Milwaukee & St. Paul at Janesville, Wis., has been promoted to day roundhouse foreman, with headquarters at Madison, Wis.

G. T. Goddard, formerly general electrical foreman in the Burnside shops of the Illinois Central, has been appointed equipment inspector of the Chicago terminal improvement department.

H. R. Seaman, gang foreman of the West locomotive shops of the St. Louis-San Francisco at Springfield, Mo., has been promoted to erecting shop foreman, succeeding A. C. Reeves.

P. J. Colligan, superintendent of motive power of the Second district of the Chicago, Rock Island & Pacific, with headquarters at El Reno, Okla., has been appointed superintendent of shops at Silvis, Ill., succeeding S. W. Mullinix, deceased.

H. J. Ray, general foreman of the West locomotive shops of the St. Louis-San Francisco at Springfield, Mo., has been appointed shop superintendent of the North locomotive shops, succeeding J. W. Surles, who has been granted a leave of absence.

Purchasing and Stores

C. J. Pearce has been appointed division storekeeper of the Shasta division of the Southern Pacific, with headquarters at Dunsmuir, Cal.

W. E. Lefaivre, purchasing agent of the Denver & Rio Grande Western, at Denver, Colo., has been appointed general storekeeper, with the same headquarters.

D. C. Curtis, general storekeeper, lines east, of the Chicago, Milwaukee & St. Paul, at Milwaukee, Wis., has been promoted to chief purchasing officer, with headquarters at Chicago.

G. M. Betterton, chief clerk in the purchasing department of the Southern Pacific at San Francisco, Cal., has been promoted to assistant purchasing agent, with the same headquarters. This is a newly created position.

Obituary

C. A. Wirth, master mechanic on the Northern Pacific, with headquarters at Pasco, Wash., died in that city on June 1.

David W. Ross, formerly purchasing agent and later general superintendent of transportation of the Illinois Central, who left railway service in June, 1905, died in New York on June 10.

George L. Potter, formerly third vice-president of the Baltimore & Ohio, died on May 31 at his home near Baltimore, Md. Mr. Potter was born on December 28, 1856, at Bellefonte, Pa., and entered railway service in 1876 as a machinist apprentice on the Pennsylvania. From 1880 to 1882 he was a machinist for this company at Renovo, Pa., and from the latter date to 1887, assistant master mechanic at Fort Wayne, Ind. From 1887 to 1893 he was master mechanic at the same point, and in the latter year was promoted to superintendent of motive power of the Northwest System, Pennsylvania Lines West. From 1899 to 1901 he was general superintendent of motive power. He was then appointed general manager of the Lines West, but resigned that position a few months thereafter to become general manager of the Baltimore & Ohio. In 1903 he was elected third vice-president of the latter road, and served until 1910, when he resigned.

Warren S. Stone, president of the Brotherhood of Locomotive Engineers and of its various banking, investment and industrial enterprises, died in a hospital at Cleveland, Ohio, on June 12, from an acute attack of Bright's disease. Mr. Stone was born on a farm near Ainsworth, Iowa, on February 1, 1860, and entered railway service in 1879 as a locomotive fireman on the Chicago, Rock Island & Pacific at Eldon, Iowa. Five years later he was promoted to engineman and, in 1903, after having served in this capacity for almost 20 years, he became grand chief engineer of the Brotherhood of Locomotive Engineers. Recently, with the multiplication of the organization's financial and industrial undertakings, a reorganization of the Brotherhood was brought about and Mr. Stone was elected president in general charge of all the union's activities, this leaving the labor activities to a newly elected grand chief engineer.

W. S. Stone

S. W. Mullinix, shop superintendent of the Chicago, Rock Island & Pacific, with headquarters at Silvis, Ill., died on June 12 in Moline, Ill., following a stroke of paralysis. Mr. Mullinix was born in Frederick County, Md., on May 12, 1859. He attended the public schools of Maryland and served an apprenticeship in the shops of the Baltimore & Ohio near Baltimore. Later he became machine shop foreman of the Chesapeake & Ohio at Huntington, W. Va. From Huntington he went to Louisville, Ky., and later to Paducah, Ky., as master mechanic of the Newport News & Mississippi Valley, now a part of the Illinois Central. After a brief period as enginehouse foreman of the Louisville & Nashville, at Louisville, he was appointed general foreman of the Central Vermont, at St. Albans, Vt. In 1903 Mr. Mullinix became master mechanic of the Kansas City Southern; in 1905, master mechanic of the Atchison, Topeka & Santa Fe at Raton, N. M., and in 1906 entered the employ of the Chicago, Rock Island & Pacific. In 1913 he was promoted to superintendent of the Silvis shops, previously having served as district mechanical superintendent at Topeka, Kan.

S. W. Mullinix

H. Englebright, who retired as master car repairer of the Southern Pacific in August, 1922, after a continuous service of 52 years with that road, died on June 5 at his home in Oakland, Cal., at the age of 73. Mr. Englebright entered the service of the old California Pacific as a blacksmith apprentice in 1869 and worked at this trade at various points until 1892, when he was appointed roundhouse and car foreman at Fresno, Cal. In 1898 he became general car foreman at San Francisco and in 1900 master car repairer at Oakland, which position he held until his retirement in 1922.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Request for change of address should reach the New York office two weeks before the date of the issue with which it is to go into effect. It is difficult and often impossible to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, be sure to send us your old address as well as the new one.

Subscriptions, including the eight daily editions of the Railway Age published in June, in connection with the annual convention of the American Railway Association, Mechanical Division, payable in advance and postage free: United States, Canada and Mexico, $3.00 a year; foreign countries, not including daily editions of the Railway Age, $4.00. When paid through the London office, 34 Victoria Street, S. W. 1, 17s. 0d. Single copy 35 cents or 1.6d.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulation (A. B. C.).

Railway Mechanical Engineer

Vol. 99 August, 1925 No. 8

When buying production machine tools

The present tendency to organize the facilities of the maintenance of equipment department with the primary objective of obtaining quantity production has led to the more general utilization of special purpose machine tools. Many of these machines are classified as distinctly special machines, but the majority of the special purpose machine tools used in railroad shops are standard types that have been equipped or converted for single-operation work. For example, there are many shops in which milling or planing machines are used solely for machining shoes and wedges; grinding machines for motion work pins, etc. In all probability an investigation would show such practices to be the rule rather than the exception. However, this development leads to a suggestion that many mechanical department officers and machine tool purchasing committees can do well to consider when about to purchase new machinery for specific jobs.

The ordinary machine tool, such as a lathe, planer or drill press is usually designed to perform a variety of jobs. Considerable extra equipment is sometimes included as part of the machine in order to make it adaptable to perform different kinds of work. However, if it is to be used for only one particular job, why buy the extra equipment? Again, there are many parts on a standard machine that could well be eliminated if it is to be used as a special purpose tool. It is in this connection that the machine tool salesman can be of real service in helping to reduce the cost if he is permitted to co-operate with the mechanical department officer or machine tool committee. Thus, instead of purchasing machine tools as equipped by the manufacturers, the railroad can purchase standard machines intended to be used on special jobs without acquiring a lot of parts which cannot be used. A saving on each machine which may amount to several hundred dollars in some cases, is well worth considering, especially if the road is placing a large order.

Getting Greater Firebox Life

One of the real problems confronting railroad mechanical departments at the present time is how to get greater life from locomotive boilers, particularly the fireboxes which are subject to the greatest temperature variations and hence expansion and contraction strains. Particularly in bad water districts, the deterioration of firebox sheets is rapid and in some cases necessitates the renewal of the entire firebox within a period of four years or perhaps less. This results in excessive cost of boiler maintenance work, both for labor and material, and possibly more serious still is the loss of the locomotive to revenue service during the period it is in the back shop for a new firebox.

In this connection the somewhat striking performance of a firebox on the Southern Pacific may be of interest. Locomotive 601, one of a lot of 10 Pacific type engines purchased from the Baldwin Locomotive Works in 1912 by the Southern Pacific Lines of Texas and Louisiana for passenger service between New Orleans, La., and Houston, Tex., was put in service in August, 1912, and, except for conditioning operations in back shop and enginehouse, has been in continuous operation since that date. The locomotive was last sent to the shop March 28, 1925, and at that time had been in service 12 years and 7 months with the original firebox, having run 1,130,880 actual miles, an average of 7,489 miles a month including the time in shop. The original firebox applied at the Baldwin Locomotive Works, was removed during March when the engine was held for general repairs.

The locomotive was in regular passenger service between New Orleans and Houston for over 10 years, and during the last two years hauled passenger trains in runs between New Orleans and San Antonio, Tex., a distance of 510 miles. The record of 1,130,880 miles run with the same firebox is unusual and indicates what can be done when proper attention is given to assure the frequent, thorough washing of locomotive boilers with hot water operation of locomotives in such a way as to minimize temperature variations under all conditions, and treatment of boiler feedwater to neutralize as far as possible its corrosive effect on firebox and other boiler sheets as well as the tubes and flues.

Accurate Costs and Business Management

In asking the Interstate Commerce Commission promptly to provide for the railroads a system of accounting which will currently and scientifically develop true costs for each primary and incidental activity in which they may engage, the seventeen representatives of the freight car repair industry who on July 14 addressed a communication to the members of the commission, have again brought into prominence a question which in one way or another has come up for discussion many times in the past. This question of cost accounting for the railroads is one with many ramifications and apparently involves a difference between the purposes of the standard form of accounts now in use by the railroads and the purposes of cost accounts which is not easy to compose. There are many difficulties in the way of a solution of this problem which will be ideal both from the standpoint of general railway accounting as well as from the standpoint of cost accounting. But it cannot be denied that there is sound reason back of the request made by the representatives of the car repair industry.

Cost accounting as it is applied in industry primarily provides the industrial executive with facts on which to

keep his production policy in proper relation to his market rather than with a means of controlling the costs themselves. Similarly, in the railroad shop, it is probable that accurate cost accounting would in most cases effect little difference in production control, for which some form of man-hour statistics are generally quite adequate. There are, however, business problems involving the policy of the railroad with respect to the purchase or manufacture of many types of material and supplies, in which costs carefully built up to include every item of overhead, such as carrying charges on the investment in buildings and equipment involved in the manufacture of the material in question, as well as superintendence and general expenses, are essential to the formulation of a sound decision. The argument that because buildings and machine tools are already available and the salaries of department and general officers must be paid, none of these items should be taken into account in figuring the cost of repairing cars and locomotives or the costs of secondary manufacturing operations, is carried too far. The fact seems to be overlooked that a blind following of this argument is likely to lead to a situation in which additions to these items become necessary because of the volume of the operations built up as a result of the fictitiously low prices at which the work can apparently be done by the railroad. Cases have been observed where in shops inadequate to meet the full demand for locomotive maintenance, building space and machine tool equipment have been devoted to whole departments actually engaged in the manufacture of machine tools for the use of the railroad, when such a policy could not possibly be justified by a comparison of costs if adequate overhead charges had been included in its own costs by the railroad. Even in the case of car repairs, the decision to make all repairs in the railroad's own shops because the expense for direct labor and material, plus shop expense, involved in doing the work in the company's own shop, is less than the contract price of the outside shop, must in the end lead to a heavy capital expenditure to provide adequate facilities to meet the maximum demand. In either of these cases it is evident that to neglect the various overhead expenses out of the calculation is fallacious.

In the interest of better business management in the establishment of equipment maintenance policies, it is evident that a compliance with the request of the representatives of the car repair industry is very much needed.

Making Better Foremen

We do not mean to imply from the title of this editorial that the foremen and supervisors in the mechanical department of American railroads have not made good. Too frequently they have been unjustly criticized. Even worse than this, foremen and supervisors who have gone to the very limit in promoting the interests of their employers, making great sacrifices of time and strength, have received not the slightest recognition or appreciation for such service. One marvels sometimes at the dogged persistence and loyalty that have characterized these men as a group, in spite of lack of recognition.

The managements, however, are in some cases open to the severest sort of censure not only because they have failed to recognize the loyalty and unselfish service of many of their foremen and supervisors, but also because they have failed to bring to the attention of these busy men the remarkable developments which have been made in recent years, in analyzing the principles of successful leadership and applying them in a scientific way. There is nothing much more spectacular or startling than the impressions made upon an average group of foremen in any industry when developments of this sort have been placed before them in a simple, understandable fashion. A notable instance of this on a railroad was the case of the Lehigh Valley foremen at the Sayre shops when they were introduced to the foremanship course developed by the Engineering Extension Department of The Pennsylvania State College. Almost as striking results have been evident when experts on management or foremanship training have appeared before other groups throughout the country either in the industries or on some of the few railroads which have attempted to face up to this problem. Incidentally some reference to a case of this kind is made in the comments elsewhere in this issue by "Output," on Bill Brown's prize article on "The Foreman and His Responsibility."

A few months ago we asked the mechanical superintendents on the different railroads for information concerning what, if anything, they were doing to promote foremanship training. The results of this investigation were summarized in the article on "Training Foremen in Leadership" which was published in our June number. One characteristic of a number of the letters received from the mechanical superintendents was the distinct request that they be fully advised of our findings—this request was so made in some cases that it indicated a real interest in the results of the study and a determination to take advantage of the good things which are being used on other railroads.

Since the publication of the article last June a number of developments have taken place which give great promise for the future in this matter of assisting the foremen and supervisors in improving their leadership ability. One mechanical superintendent, for instance, has appointed an assistant who will give his entire time to this question of training and coaching the foremen and otherwise helping to improve relations between the workers and the management. This assistant will not only receive thorough co-operation and encouragement from his immediate superior and the management in general, but will be furnished with such expert assistance as may be found desirable. Other mechanical department superintendents have indicated that they will assist the foremen and supervisors in every way possible, either through the formation of foremen's clubs for consideration of the principles underlying successful foremanship, or in the organization of study classes or other things which will be helpful to the foremen. Then, too, some of the groups which have been studying this problem have indicated a desire for information as to special topics for discussion which will assist them in carrying on their studies in a larger and more advanced way.

It is significant that several chief executives in looking over the June number of the *Railway Mechanical Engineer* specifically commented upon the first prize article on "The Foreman and His Responsibility" and the study or summary on "Training Foremen in Leadership." This should be a distinct encouragement to the mechanical department officers and foremen in going foreward with this good work. The *Railway Mechanical Engineer* is also interested in doing anything it can to be of assistance and to direct the studies and discussion along the right lines. Incidentally, in this connection we desire to direct special attention to the three rather interesting comments in this issue on the first prize article on "The Foreman and His Responsibility."

One of these comments is in the form of a very drastic criticism of Bill Brown's suggestions and philosophies. It comes from a man who apparently has very little sympathy with the modern tendency of the application of the Golden Rule to our industrial and transportation activi-

ties. We may designate him as of the "hard boiled" type, but nevertheless his attitude is that of a considerable number of foremen and supervisors in the mechanical departments of our railroads today. This must be clearly recognized and squarely faced, because the foremen are the very keystones in the mechanical department organization. This particular communication is signed "Top Sergeant" at the request of the writer of the article. Presumably he intends to reflect the so-called military attitude, although if we understand the new developments in the army of the United States, it is vastly different from that which is voiced by "Top Sergeant." Today the progressive leaders in the army apparently feel that the very highest morale can be engendered only when each man in the army is critically studied and then is so placed and developed that he can make the very best possible use of those particular talents with which he is endowed. Is it not true that the morale of a railway organization is also dependent upon helping the men to find that particular class of work for which they are best fitted and to assist them in so developing themselves that they can be of the greatest possible use and satisfaction both to themselves and the company for which they work—and in making this statement we do not mean to infer that the men should be exploited or worked beyond reasonable limits.

It will be noted that two of the comments on Bill Brown's article are in more or less agreement with Bill Brown, except that they emphasize or more fully dwell upon some of his suggestions. Closely related to these comments and forming a rather masterful discussion of the entire question of foremanship, is the presentation made by the winner of the second prize in the competition—John H. Linn, assistant supervisor of apprentices on the Santa Fe. It would be difficult to pack a greater amount of real information and inspiration on this foremanship question into so small a compass as occupied by Mr. Linn's discussion. Indeed, any group of ambitious foremen who will plan a series of discussions based on the two prize articles in this competition and the comments on Bill Brown's article in this issue, will find enough live topics to keep them going throughout an entire season.

Incidentally, we very greatly appreciate the co-operation given by those who have written to us about Bill Brown's article. The comments that we are publishing are thought-provoking and promise to be most helpful in encouraging foremen and supervisors to think this problem through to a logical conclusion. We wish we might have still more criticisms and comments. "Top Sergeant" has gone after Bill Brown in great shape, but Bill Brown is something of a fighter and years of practical experience and success as a foreman and shop superintendent have splendidly equipped him to support and back up his contentions. Could anything be more helpful to the foremen and supervisors in the mechanical department than a lively, straight-from-the-shoulder discussion of this question in our columns? We shall be glad to hear from any of our readers on either side of this question. The harder you hit, the better.

New Books

SUPERHEAT ENGINEERING DATA: *A handbook on the generation and use of superheated steam. Sixth edition, revised. Bound in keratol, 4½ in. by 7 in., 208 pages, 85 illustrations and diagrams, 69 tables. Published by the Superheater Company, New York. Price* $1.00.

This handbook contains condensed data for steam power plant engineers and operators. A feature of the book is the index consisting of 16 pages, which assures ready reference. Superheated steam, its advantages over saturated steam and the proper design and performance of superheaters, are briefly discussed. It illustrates superheater arrangements in practically all stationary, marine and locomotive type boilers commonly made in America. Waste heat, portable and separately fired superheaters are also shown. Brief comparative data is given as to sizes, tube sizes, arrangement of tubes, etc., for the stationary water tube boilers which are illustrated. The steam tables cover pressures from below atmospheric to 600 lb., absolute, and include properties of superheated steam from 50 deg. to 300 deg. F. superheat.

The section on piping includes information for figuring piping for handling water, saturated and superheated steam and velocity and pressure drop of water and steam flowing through piping. In this section is included the standard weights and pipe flanges for high pressures proposed by the American Engineering Standards Committee. This book also contains engineering data on coal and oil-fired boilers, which include tables of heat values for gaseous, liquid and solid fuels. Other miscellaneous data include complete conversion tables and data on bolts and screw threads, with the recent work of the American Engineering Standards Committee and the National Screw Thread Commission. There are also many miscellaneous tables frequently used by steam engineers.

What Our Readers Think

Minimum use of figures when setting Walschaert gear

PROCTOR, Minn.

TO THE EDITOR:

I have read with interest Mr. Sparrows' article which appeared on Page 77 on the February issue of the *Railway Mechanical Engineer* and do not feel content to sit on the side lines and let this article go by without a reply which he solicits. I agree that the fewer figures used the less liability there is for a mistake.

I will briefly outline the method of setting the Walschaert gear used on the Duluth, Missabe & Northern and approved by our officers. If the engine is to have new main crank pins they are turned and milled with the proper size key-way on the eccentric crank fit of the pin. They are then placed on a face plate shown in Fig. 1, with the two centers leveled up. We have a templet, Fig. 2, for each class of engines, *A C* being made equal to one-half of the crank pin throw, *A B* equal to the length of the eccentric crank arm and *B C* equal to one-half of the eccentric throw circles. With the side *A C* of the templet resting on the face-plate the pin is turned until the center of the pin and the center of the key-way line up with the side *A B* as shown in Fig. 1. Then with a surface gage set to the center of the pin, the line *x y* is scribed on the side of the pin at the back end. When pressing the pin in the hole, the line *x y* on the pin should register with the line *x, y,* on the wheel as shown in Fig. 3. One side of this templet is placed outward for right pins and the opposite side placed outward for left pins. Care should be taken to use it properly and it should be marked to avoid confusion.

The next operation is the setting of the crank arm to the proper throw by the use of the gage shown in Fig. 4, drill and ream the hole for the bolt and fit the key. All motion parts should be checked to see if they compare with the drawings.

The first procedure in setting valves, after getting the port marks and dead centers, is to check the suspension of

the radius bars. The reverse lever is placed so that, the link block on one side is exactly in the center of the link. This can be checked by moving the link forward and back with the eccentric rod disconnected and noting when no motion is conveyed to the valve. The other side should now be examined to see if it is exactly central which, if not, indicates that the length of the radius bar hanger must be altered. To ascertain the amount of alteration required, first tram the lifter arm from some stationary

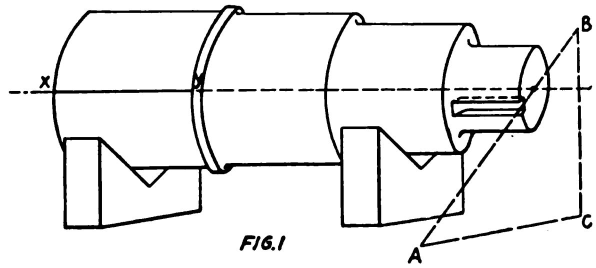

FIG. 1

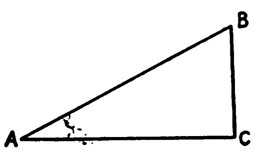

FIG. 2

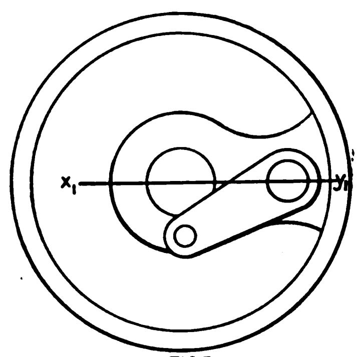

FIG. 3

Fig. 1—Crank pin placed on the face plate preparatory to laying off key-way; Fig. 2—The templet used for each class of locomotive; Fig. 3—Line X Y on the pin should register with line X_1 Y_1 on the wheel when pressing in the pin

point either directly above or directly below it then move the reverse arm until a perfectly still valve is found when rocking the link. Then tram the lifter arm again from the same point with the same tram. The distance between the two tram marks denotes the change required on one hanger in order to have both link blocks centered at the same time. Nothing else preventing, the short hanger may be lengthened this amount.

The following method is used to get the proper length of the valve stem and eccentric rod. With the reverse lever in the position that will exactly center the link blocks, revolve the main wheels and mark the extreme travel of the valve upon the valve stem. The port opening obtained at each end is the lead of the valve and if the leads are not equal the valve stem should be altered one-half the difference. We do not make a practice of changing the length of the radius bar. The change is made on the valve stem by pulling the valve out of the chamber and facing the collar or applying a faced washer between the spider and the collar as the case demands. It must be remembered that new port marks have to be taken when the valve is replaced.

Let it now be said that the valve stem is the proper length. Our attention will be now on the eccentric rod.

Placing one side of the locomotive on dead center the link should be exactly plumb and moving the link block from one end of the link to the other should not move the valve. If the valve moves, it indicates that the link is not plumb, as shown by the dotted lines in Fig. 5. The eccentric rod must be altered to make it plumb. Tram from the foot of the link to the guide yoke as at *a*, then revolve the main wheels slightly to plumb the link. (By moving the link block from one end of the link to the other, the link is known to be plumb when no motion is conveyed to the valve.) After the link is plumb tram again as at *b*. The difference between *a* and *b* is the amount necessary to alter the length of the eccentric rod. The same method applies on the other side of the locomotive.

The leads of the valves are now square. It is a known fact that the points of cut-off are not always square with the leads.

10	10½
10	10½

Fig. 6

If the cut-offs in the running position show up as shown in Fig. 6 it indicates a valve rod change to square up the valve. The amount of change is determined in the following manner. Return to the shortest cut-off point, in this case 10 in., from the back end of the stroke, and the tram falls in the port mark on the valve stem. Revolve the wheels until the crosshead is 10¼ in. $\left(\frac{10 + 10\frac{1}{2}}{2}\right)$ from the back end of the stroke and tram again on the valve stem. To square the cut-off the valve rod should be changed a sufficient amount to bring the port mark under the tram at this position.

10½	10
10	10½

Fig. 7

If the cut-off in the running position shows up as in Fig. 7 it would be necessary to make a slight eccentric rod change to square up. The amount of change may be

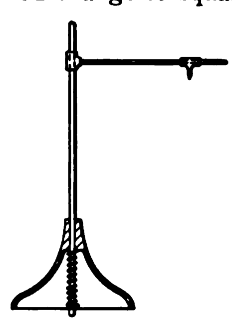

FIG. 4

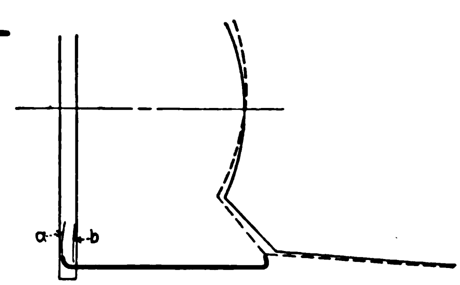

FIG. 5

Fig. 4—Gage used when setting the crank arm to the proper throw; Fig. 5—Method of training a link to make it plumb

determined in the following manner. With the reverse lever remaining in the forward position and in the same notch as when the cut-off was taken, return to the short cut-off, 10 in. from the front end of the stroke and tram from the foot of the link to the guide yoke. Revolve the wheels until the crosshead is 10¼ in. $\left(\frac{10\frac{1}{2} + 10}{2}\right)$ from the front end of the stroke and tram again from the foot of the link to the guide yoke. The eccentric rod should be altered the amount between the two tram marks to square the cut-off. The last two changes, if made, will of course make a variation in the leads and one must be conservative in making changes, not go to the extremes.

The evaporative capacity of locomotive boilers

A new formula is proposed for determining the relationship between the rate of evaporation and the rate of combustion

By Alexander P. Poperev

Part I

AMONG the different problems of railway mechanical engineering yet waiting a satisfactory solution, is that of accurately predetermining the evaporative capacity of the locomotive boiler for any given set of conditions. When we take into consideration the fact that it is the boiler rather than the engine, which determines and limits the capacity of the locomotive, it will be understood why an accurate solution of this problem is so important to the railroads as well as to the locomotive builders.

The present method of handling this problem is far from being commensurate with its importance, at least as far as its accuracy is concerned. Various cut and dry rules commonly used that are derived from practice, are too general and do not go further than to give a rough idea about the usual proportionality between dimensions of the boiler and the tractive force of the locomotive. Likewise, from experience we know approximately how much steam can be produced under average conditions by the unit heating surface of the locomotive boiler. Nevertheless, with all the years of experience and knowledge, when it comes down to the question, "given a certain locomotive and fuel, how much steam can be produced at a certain rate of combustion?"—one has either to guess or run an experiment. However, it is just this question that both the railroads and the locomotive builders would like very much to have answered.

An intelligent and accurate answer to this question evidently requires the knowledge of a general law, governing the relationship between the evaporative capacity of the locomotive boiler and the various factors affecting it. Neither a theoretical nor experimental study of the question, however voluminous it may be, has as yet given a general mathematical expression of the above law. The problem is far too complicated. However, there has been accumulated a considerable amount of experimental data, which permits the study of the influence of various factors, at least the most important ones, as to the evaporative capacity of the locomotive boiler.

The writer has been interested in this question for some time and he aims in this article to discuss certain results of a personal study covering a considerable period of time. Considering the performance of the locomotive boiler to be entirely independent from the engine and subject to its own particular laws, it has been found possible, from available experimental data, to arrive at certain formulas, purporting to express the relationship between the evaporative capacity of the locomotive boiler and some of the most influential factors affecting it. The resulting expressions cover a sufficiently wide range of conditions, as much as available experimental data would permit, and are fairly accurate. In order to avoid the inconvenience of using a somewhat complicated and unwieldy resulting formula, the construction of a diagram is worked out, whereby necessary computations may be made graphically in a very simple manner.

While the suggested expressions, being dependent upon the available experimental data, are not to be considered as final ones and refer only to a certain range of conditions, it is believed that they will be of some interest to the engineering profession, as they are even at this stage of development fairly applicable in practice, and a somewhat different method of their derivation offers a wide field for further experimental study and research.

THE author of this article, Alexander P. Poperev, is a Russian engineer. For a considerable period of time he was associated with Prof. G. V. Lomonossoff as a testing and research engineer in the experimental study of locomotives for the Russian State Railways where the idea of deducing the general equation described in this article for determining the capacity of locomotives was originated. He received his education at the Polytechnical Institute at Petrograd and is also a graduate of Massachusetts Institute of Technology.

Factors determining the capacity of the boiler

Even an elementary study of the performance of the locomotive boiler shows that there are a considerable number of factors which determine its evaporative capacity. A general analysis and experimental study leads to the conclusion that the following three factors may be considered as the most important ones; namely, type and dimensions of the boiler, kind and quality of fuel, and the rate of combustion.

The effect of other factors appears to be comparatively small. For the sake of simplicity, we may, therefore, neglect them without serious error and to assume, as a first approximation, that the capacity of the locomotive boiler is determined by the above three factors only. This assumption, as we shall presently see, is sufficiently accurate for average practical purposes.

Our next problem will then consist of determining the

relationship between the capacity of the boiler and these factors and finding for it a suitable mathematical expression. As the theory is not yet sufficiently developed to derive it in a purely analytical way, we will have to derive it empirically from available experimental data. Luckily, available experimental data permits at least to a certain extent, the analysis of the influence of each factor separately and to express it by a formula. We shall begin with a study of the relationship between the capacity of the boiler and the rate of combustion.

Relationship between the capacity of the boiler and the rate of combustion

It was noticed long ago that the rate at which fuel is burned has a marked effect upon the rate at which steam is produced by the boiler, and that there exists a definite relationship between the two. For some reason difficult to understand, this most important relationship has not been given the attention it rightfully deserves, and as we shall presently see, there has not been suggested, as yet, a general formula for this relationship which could account for all the characteristic properties and be considered as correct.

In this article the evaporative capacity of the boiler is referred to as the equivalent rate of evaporation (pounds of steam, produced at and from 212 deg. F. by one sq. ft. of heating surface, per hour) as this form lends itself conveniently for comparative analysis of the performance of boilers with different characteristics. The rate of combustion is expressed in pounds of dry fuel, burned per sq. ft. of grate area per hour. If the values of the rate of evaporation Z are plotted as ordinates against the corresponding values of the rate of combustion Y as abscissae, a smooth curve will be obtained, which graphically represents the relationship between the values of Z and Y. Such curves are presented in a way of illustration in Fig. 1, and the first thing which attracts our attention is that while they refer to most diversified boilers and fuels, yet the general shape of all the curves is manifestly the same.

It has been found, by checking with all available experimental data, that curves of a similar character are invariably obtained for any kind of boiler and fuel which leads us to the conclusion, and a very important one, that the rate of evaporation varies with the rate of combustion according to some general law. Let us then see by what kind of formula we could express the relationship between these factors. We shall approach this question by analyzing a few formulas suggested by various investigators and at the same time endeavor to learn some of the characteristic properties of this important relationship.

The straight line formula

That the relationship between Z and Y cannot be correctly expressed by a straight line equation is quite evident directly from the plots. However, many investigators still believe it to be sufficiently correct, but it is perhaps worth while to show that it is not true even for rough approximation. First of all the straight line formula necessarily assumes that for any given boiler and fuel, the proportion of losses in a boiler is constant and independent of the rate of combustion. This is not true, and as we shall see later, the experiments show quite definitely that the losses increase and rather rapidly with the rate of combustion, particularly in the locomotive boiler. But the best way to show its fallacy is in a purely algebraic way. Usually this equation is quoted in the following general form:

$$(1) \quad Z = a + bY$$

where Z and Y represent, as before, the rates of evaporation and combustion respectively, and a and b are certain positive constants for a given boiler and fuel. Now, suppose $Y = O$; we then come to an absurd conclusion, that when no fuel is burned at all, the rate of evaporation, according to this formula, is still a definite quantity equal a, which is evidently impossible.

The Dr. Goss formula

At sufficiently high rates of combustion, the Z-Y curve deviates considerably from the straight line, which plainly indicates that its equation must necessarily be of higher order than the first. Based upon his well known experiments with locomotives, Dr. Goss suggested the

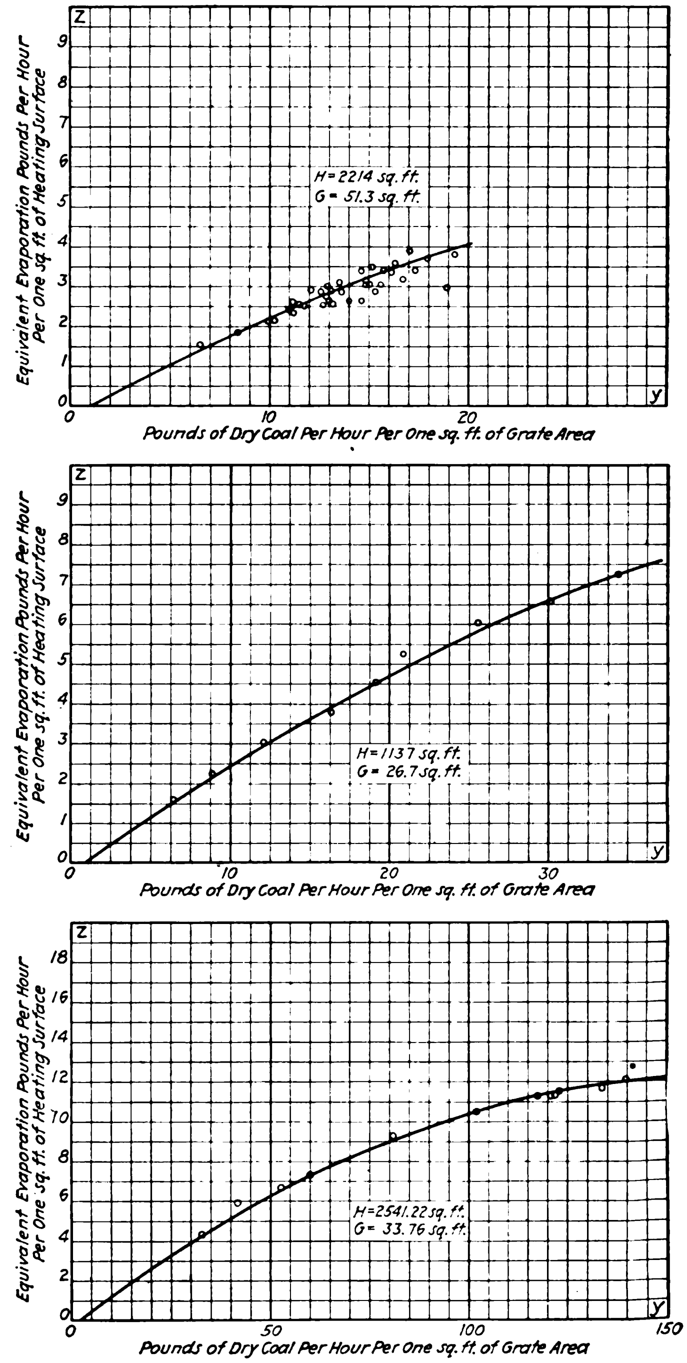

Fig. 1—Top chart, tests made on a Babcock & Wilcox boiler at the Massachusetts Institute of Technology; Center chart, Whitman's tests on a horizontal return tubular boiler; Bottom chart, Pennsylvania Railroad Company tests on a locomotive boiler

following expression for the relationship between the capacity of a boiler and the rate of combustion.[1]

$$(2) \quad C = \frac{W}{a - bW} \text{ in which}$$

C = the total amount of fuel consumed per hour, lb.
W = the corresponding total amount of steam produced, lb.
a and b are constants.

This expression was not obtained directly, but was derived from the relationship between the evaporation per pound of fuel E, and the rate of evaporation per square foot of heating surface H. After a careful selection of corresponding experimental data, Dr. Goss assumed, that the relationship between E and H can be sufficiently correctly expressed by the linear equation

$$(3) \quad E = a - b_1 H$$

where a and b_1 are certain positive constants for a given boiler and fuel. E and H can also be expressed through

$$E = \frac{W}{C}$$

and

$$H = \frac{W}{S}$$

where S is the total amount of heating surface of the boiler.

Equation (2) was obtained by substituting in equation (3) the above values of E and H. By plotting equation (2) it was found, that although it was derived in a somewhat indirect manner, nevertheless it did fit well the values of C and W obtained directly by experiment. This fact was considered as a sufficient proof that equation (2) is correct and has been endorsed since then by other investigators[2]. However, this is not always the case, and it is possible to show that equation (2) does not represent the relationship correctly.

Rewriting equation (2) in a somewhat different manner

$$(2a) \quad \ldots\ldots\ldots\ldots \quad W = \frac{aC}{1 + bC} = \frac{a}{b + \frac{1}{C}}$$

it can be readily seen that according to the equation, the value of W steadily increases with the rate of combustion C and reaches its limiting value $\frac{a}{b}$ at an indefinitely large value of rate of combustion, $C = \infty$. This fact is not substantiated by experiment. On the contrary, experiments show[3] quite clearly that the maximum rate of evaporation occurs at certain definite, and not indefinitely large rates of combustion and after reaching it, it has a marked tendency to decrease, notwithstanding the fact that the rate of combustion continues to increase. Such a behavior of the Z-Y curve can be readily explained by the fact, that various losses in a locomotive boiler increase very rapidly with the rate of combustion. For instance, loss due to sparks and cinders increases nearly as the square of the rate of combustion as it has been found by Dr. Goss's experiments.[4] It is evident, that at such an extensive rate of increase, the effect of this loss alone can check a further increase in the rate of evaporation and then force it down.

On the other hand, from equation (2) it follows that if $C = O$, then $W = O$ also. It would be so if we had had an ideal boiler, with no losses whatsoever; but in an actual boiler certain losses are always present, so that evaporation actually does not start until the rate of combustion reaches a certain value Y_o, usually rather small, at which the heat developed by the fuel is just enough to cover various heat losses. The value of Y_o, that is the minimum rate of combustion, necessary to keep the boiler in thermal balance, and which corresponds to a zero rate of evaporation, is very easily determined by experiment, by firing the boiler just enough to keep the pressure constant with all the steam shut off and measuring the amount of fuel consumed. Its importance for correct shaping of the Z-Y curve can be readily appreciated, and in tests made by the Russian State Railways, this experiment constituted a regular part of the test program for each locomotive.

It is also evident, that when the rate of combustion is smaller than Y_o, the heat developed by the boiler will not be sufficient to make up various heat losses; the thermal balance will be disturbed, and the boiler will cool off; in other words, at values $Y < Y_o$ we will have negative rate of evaporation. It follows, therefore, that when no fuel is burned at all, that is when $Y = O$, the correct formula for the relationship between Z and Y should give a certain negative value Z_o for the rate of evaporation which will represent the aggregate value of heat losses, when no outside heat is supplied to the boiler. We see, that equation (2) also fails to satisfy this condition. After all, the fundamental equation (3) from which equation (2) was derived, is not correct by itself. When $H = O$ from equation (3), it follows that $E = a$, which is obviously wrong. Thus we see, that from the above considerations Dr. Goss's formula fails to represent correctly the relationship between the capacity of the boiler and the rate of combustion.

Lawford H. Fry's formula

An empirical formula for the relationship between the rate of combustion was also suggested recently by Lawford H. Fry[5] which he developed in a manner similar to Dr. Goss; only in this case a linear relationship was assumed between the efficiency of the boiler F and the rate of combustion G. This relationship, according to Mr. Fry, can be expressed as follows:

$$(4) \quad \ldots\ldots\ldots\ldots \quad F = m - nG$$

where m and n are certain constants for a given boiler and fuel. From a general definition of the efficiency of a boiler

$$\text{Efficiency} = \frac{\text{Heat utilized}}{\text{Heat consumed}} = \frac{WSk}{GRK} \times 100 = m - nG$$

he obtains

$$(5) \quad \ldots\ldots\ldots\ldots \quad W = \frac{nG - nG^2}{K_oC}$$

where

$$C = \frac{\text{Heating surface}}{\text{Grate area}} = \frac{S}{G}$$

W = the rate of evaporation, lb. per sq. ft. of heating surface.
K = the heating value of fuel in B.t.u. per lb.
k = the heat in B.t.u. required to produce 1 lb. of steam from feed-water.

$$k_o = \frac{100}{K}$$

The above formula (5) suggested by Mr. Fry, fits the experimental data quite well, as it can be seen from diagrams, presented by Mr. Fry.[6] Besides, it accounts for the existence of a maximum rate of evaporation corresponding to a certain definite rate of combustion and from this point of view this formula is undoubtedly more correct than the one suggested by Dr. Goss.

Nevertheless, there are convincing reasons for doubting the correctness of the method, accepted by Mr. Fry,

[1] Locomotive Performance, by Dr. W. F. Goss, p. 151.
[2] Transactions, American Society of Mechanical Engineers, Volume XXII, p. 490; Proceedings, Institute of Mechanical Engineers (London) 1908, p. 269.
[3] The Engineer (London), 1920, p. 327.
[4] Engineering (London), 1913, pp. 485, 564.
[5] Engineering (London), 1921, p. 125. A Study of the Locomotive Boiler by Lawford H. Fry, p. 46.
[6] A Study of the Locomotive Boiler by Lawford H. Fry, p. 105.

for derivation of his formula and incidentally, the correctness of the formula itself. Mr. Fry does not advance any reason for the assumption of a straight line relationship between the efficiency of a boiler and the rate of combustion, except the statement that the straight line fits experimental data fairly well. But the analysis of the performance of a boiler brings us to a conclusion that the efficiency of a boiler varies with the rate of combustion according to a more complex law than the linear. We have seen that at a certain rather small value of the rate of combustion Y_0, the rate of evaporation is zero, as all the heat developed is taken up upon covering the various heat losses. The efficiency of the boiler, corresponding to this rate of combustion Y_0 is evidently zero. With the increase of the rate of combustion, the effect of the losses, which are constant and independent from the rate of combustion, that is radiation losses, leaks, etc., rapidly decreases. On the contrary, the effect of losses, proportional to the rate of combustion, rapidly increases.

At a certain value of rate of combustion these two opposing factors balance each other. The proportional loss of heat at this point will be minimum and the efficiency of the boiler will have its maximum value. In other words, the general considerations lead to a conclusion that the curve, representing the variation of the efficiency of a boiler with the rate of combustion, can not be a straight line, but must be of a higher order. The experience of Babcock & Wilcox Company[7] seems to prove that with sufficient evidence, and, on the other hand, as the writer showed some time ago, that this relationship can be satisfactorily expressed by an equation of a second order.[8] Again, the basic formula (4) contradicts the general definition of the efficiency of a boiler as quoted above. At zero rate of combustion, the efficiency of a boiler evidently can not have a maximum or any definite value. Finally, the formula (5), suggested by Mr. Fry, gives for the zero rate of combustion the value of the rate of evaporation equal to zero also, while, as we have seen, it should be negative. The above considerations seem to be sufficient to consider Mr. Fry's formula (5) and his method of derivation as also failing to express correctly the relationship between the evaporative capacity of a boiler and the rate of combustion.

Characteristic properties of the relationship between the evaporative capacity of the locomotive boiler and the rate of combustion

Let us summarize the various characteristic properties of this important relationship which we have found by analyzing different expressions for it. We have found that:

a—The general character of the curve, representng this relationship is the same for any type of boiler or kind of fuel; i.e., it is independent from both these factors.

b—It has a maximum at a certain definite, and not indefinite rate of combustion.

c—At the zero rate of combustion, the rate of evaporation is not zero, but is a certain negative quantity, equivalent to the aggregate heat losses of the boiler.

As we have seen, neither of the suggested formulas for this relationship could account for all of the enumerated characteristic properties of this relationship and for that reason, neither of them can be considered as a sufficiently correct expression of it. This failure can be largely attributed to a somewhat incorrect method of deriving these formulas; namely, from some secondary relationships, instead of utilizing original values of Z and Y, obtained directly from experiment. We hardly can agree with Mr. Fry, that such an indirect method is the best. It would be so if the secondary relationships were very simple or their properties were well known. Such is not the case and consequently the reverse method of procedure, namely finding at first a general expression of the basic relationship between Z and Y directly from original experimental data, would seem to be more rational, as then all the secondary relationships between the rate of combustion and efficiency, etc., can be derived easily in a purely algebraic way. Such a method of procedure has been adopted by the writer.

Expression suggested by the author and its analysis

Quite sometime ago,[9] the author suggested the following general formula to express the relationship between the rate of evaporation and the rate of combustion:

$$(6) \quad Z = -a + bY - cY^2$$

where

Z = the rate of evaporation, in pounds per sq. ft. of heating surface per hour.
Y = the rate of combustion in pounds per sq. ft. of grate area per hour.
a, b and c = co-efficients, which are constant, for a given boiler and fuel. In general they are functions of both these factors.

This expression was tried by the author on all available experimental data referring to both stationary and locomotive boilers and in every case, without exception, it was found, that formula (6) fits the experimental data in a satisfactory manner.

Let us now check its correctness by applying to it an analysis similar to the above. At the rate of combustion equal zero, $Y = O$, the rate of evaporation, according to formula (6), is negative, that is $Z = -a$. As we have seen from the above, it is one of the characteristic properties of the relationship between Z and Y and is accounted for by the suggested formula.

With the increase of the rate of combustion, the rate of evaporation steadily increases until it reaches its maximum value, which, according to the formula (6), is

$$(7) \quad Z_{max} = -a + \frac{b^2}{4c}$$

which occurs at the rate of combustion equal to

$$(8) \quad Y_{z=max} = \frac{b}{2c}$$

The expressions (7) and (8) are found by equating the first derivative of the formula (6) to zero and solving for Z and Y. As the coefficients b and c are always definite positive quantities, the value of $Y_{z=max}$ will be definite also.

Significance of the coefficients of the formula (6) and its graphical representation

It is interesting to note that although formula (6) is purely empirical, its terms nevertheless can be ascribed as having a definite physical significance. Let K represent the heating value of one pound of fuel and r equal the heat necessary to produce one pound of steam. If G and H will denote respectively the values of the grate area and the heating surface, then the maximum theoretically possible value of the rate of evaporation at the rate of combustion y will be

$$Z_{theor.} = \frac{KGy}{Hr}$$

For any given boiler and fuel, the coefficient b in the expression (6), as well as the ratio $\frac{KG}{Hr}$ are constants.

[7] Steam. Babcock & Wilcox Company, 35th edition, page 284.

[8] Engineering Messenger (Petrograd), 1915, No. 23. A note on the question of the relationship between the efficiency of the locomotive boiler and the rate of combustion, by A. Poperev.

[9] Engineering Messenger (Petrograd), 1915, No. 23. A note on the question of the relationship between the efficiency of the locomotive boiler and the rate of combustion by A. Poperev.

Therefore, it will be entirely correct to express the value of the coefficient b in the following manner:

$$b = \frac{KG}{Hr} - n$$

where n is a certain yet unknown constant.

Substituting this value of b into expression (6), we have:

$$\begin{aligned} Z &= -a + bY - cY^2 \\ &= -a + \left(\frac{KG}{Hr} - n\right) Y - cY^2 \\ &= \frac{KG}{Hr} Y - (a + nY + cY^2) \\ &= Z_{theor.} - Z_{loss.} \\ &= Z_{theor.} - (Z_a + Z_n + Z_c) \end{aligned}$$

The significance of the coefficients a and c of the expression (6) can thus be seen at once. They evidently

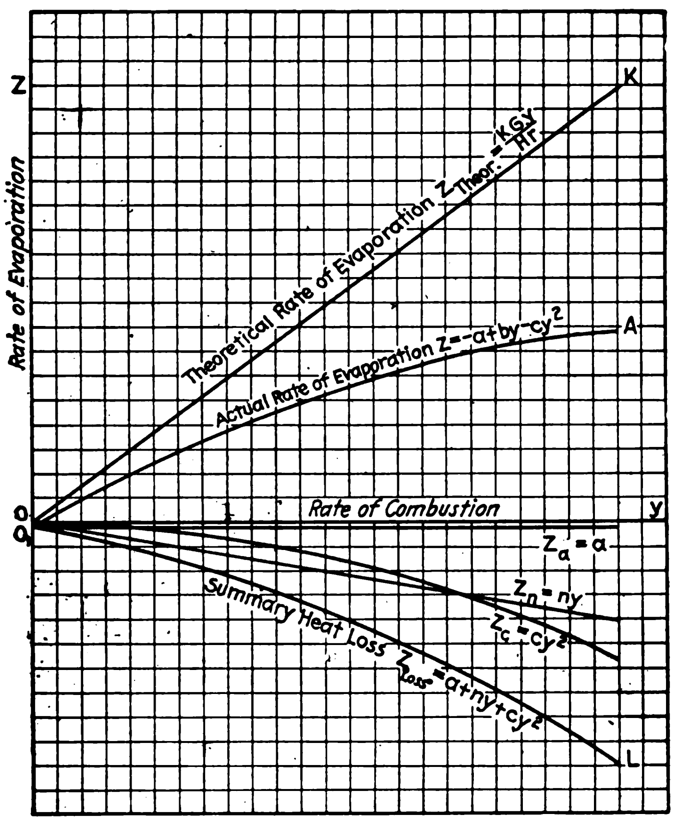

Fig. 2

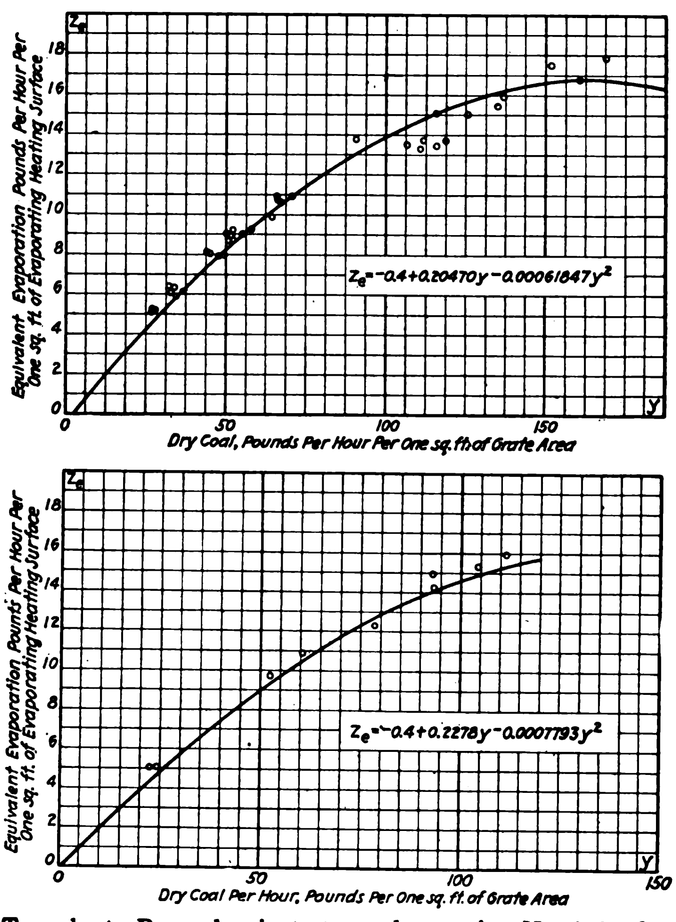
represent heat losses in the boiler, expressed in terms of rate of evaporation. The coefficient a represents the summary heat loss, which is constant and independent from the rate of combustion, while the coefficient c represents the summary heat loss, proportional to the square of the rate of combustion.

The constant n evidently represents a summary heat loss directly proportional to the rate of combustion, and therefore, the coefficient b represents the difference between the theoretical value of the rate of evaporation Z_{theor} and the equivalent heat loss, directly proportional to the rate of combustion.

The above can be conveniently represented graphically as shown in Fig. 2. By plotting values of Z_a, Z_n and Z_c we obtain three curves, each of which represents a summary heat loss, expressed in terms of the rate of evaporation, namely the summary heat loss Z_a, independent of the rate of combustion then Z_n directly proportional to the rate of combustion and finally Z_c proportional to its square. Adding the ordinates of these three curves for each value of y, we obtain the curve O_1—L, which represents graphically the total heat loss and how it varies with the rate of combustion. Subtracting the ordinates of the curve O_1—L from the corresponding ordinates of the straight line O—K which represents the maximum theoretically possible value of the rate of evaporation, we obtain the final curve O_1—A which represents the actual rate of evaporation as it is expressed by formula (6).

Fig 2 illustrates graphically that formula (6) is based on the assumption that the heat losses in a locomotive boiler can be divided into losses, independent of the rate of combustion and losses proportional to the first and second power. Unfortunately, no experimental study of the various losses in the locomotive boiler is known to the writer which would be complete and accurate enough to check numerically this assumption. However, it is quite reasonable to suppose that this assumption is very near to what actually takes place in the boiler. For instance, such heat losses, like leakage, radiation loss, etc., are obviously independent from the rate of combustion.

Again, there are no direct experimental data, which would show, which losses are directly proportional to the rate of combustion; but it is quite reasonable to assume that the loss through the grate, as well as the loss through ash and clinkers is directly proportional to the rate of combustion. On the other hand, we have direct



Top chart—Pennsylvania tests on locomotive No. 790, class Ils. Bottom—Dr. Goss' tests on Jacobs-Shuppert and radial stay boilers

experimental proof, that certain losses, like loss due to sparks and cinders are nearly proportional to the square of the rate of combustion, as it is shown by tests run at the University of Illinois[10] and at the Altoona, Pa., test plant of the Pennsylvania Railroad.[11]

[10] University of Illinois Engineering Experimental Station Bulletin No. 82.
[11] Pennsylvania Railroad Company—Test Department Bulletin No. 21, p. 43.

In summarizing our discussion of formula (6), suggested to express the relationship between the rate of evaporation and the rate of combustion, the following can be stated:

a—The suggested formula satisfactorily fits the experimental data.

b—It accounts for all of the characteristic properties of the relationship.

c—While being strictly empirical, its terms have a definite physical significance, which agrees with general considerations as well as with tests.

The above considerations seem to be of sufficient weight to consider the above formula, if not an exact one, as at least being a sufficiently accurate expression for the relationship between the rate of evaporation and the rate of combustion and to use it as a basic formula for deriving a more or less general expression for the capacity of the locomotive boiler and various secondary relationships.

(This discussion will be continued in the September issue, in which a practical application of formula (6) will be given.—Editor.)

"Bill Brown" started something

A hard-boiled foreman gets after him—Two other interesting and pertinent comments

Our June Shop Equipment Number received an usually cordial and warm welcome. Comments have been received from many sources as to the practical value of several of the more important articles; an unusual number of expressions, however, concerned two of the articles which were more or less closely related. A chief executive of a southern road observes, for instance, "As you can imagine, my particular attention centers in the articles 'The Foreman and His Responsibility' and 'Training Foremen in Leadership.'"

The first of these received the prize for the best article in the *Railway Mechanical Engineer* competition on the responsibilities and opportunities of the foreman (the second prize article will be found elsewhere in this number); the second article was a round-up or study of the methods used in the mechanical departments for coaching or training the foremen and supervisors in the art of leadership and the better understanding of human relations.

Space will not permit publishing all of the worth-while comments which were received. We have selected three, however—one from an old-fashioned, hard-boiled type of foreman and two others from men who are seriously trying to think through the questions of efficient leadership and human relations in the mechanical department. These comments are published in the hope that they will stimulate further thought and discussion on the observations which were made by "Bill Brown," as well as those made by others who participated in the competition on the responsibilities and opportunities of the foreman and whose articles will appear in this and future issues of the *Railway Mechanical Engineer.*

"Bill Brown" drastically criticized

To the Editor:

Referring to the suggestion on page 322 of the June *Railway Mechanical Engineer* and the question: Do you agree with "Bill Brown" in his article on the foreman and his responsibilities.

Well, I'll start the ball rolling by saying emphatically, "NO"!!!

In the first place, I think he should have told his foreman when he joined the band that quite probably he would want to get off for a day in the near future, explaining why. Then he would have been running no chance of creating confusion in the band by finding at the last minute that he could not get away. Why should a railroad shopman play in a town band anyway? His first consideration should be looking after his job and I think his foreman was very considerate in giving him the warning he did.

Then again, if Bill Brown had been as observant as he should have been, and as possibly he has now become, he should have noticed his increase in pay, even though it was small, and should have acknowledged his appreciation with thanks to his foreman for obtaining it—which is only what common courtesy would demand. If he was working for the writer he would get no more increases through him.

The new foreman—What an easy mark Bill Brown appears to be in calling together and speaking to his men as he did. If he worked for the railroad as the writer does, he would have no opportunity to call his men together for any such purpose the second time. He would very probably, and, in my opinion, quite justly, be "canned" by our superintendent motive power as being unfit supervising material.

One may think I am hard-boiled. But is there not too much of this brotherly love stuff being preached? What does it get a foreman but presumptious imposition in most cases? Were the writer in the position of the new foreman mentioned, I would more probably say to the first guy that I found not in absolute accordance with my plans and views: "There are your instructions. Carry them out and quickly too, or the gate for yours. I'm put in here to run this department and by G——, I'm going to run it. Those who put me here think I can do it and I'm going to show them I can. And any guy here who thinks he can stall on me might just as well get packed up."

I'm sure a little rough stuff at the start will have a far greater desired effect than the Sunday School meeting Bill writes of.

He says he is assuming the foremen wish to keep their men. Why does he assume that? Who wants to keep men who are not pulling with him? Show the gate to about two of them and see how quickly the others will get into line. This is not to be done as suggested by Bill as a *last* resort, but as a very *first* one.

Keep acquainted with men's point of view—What time has he for that even if it were a desirable thing to do?

What should a real *he man* foreman care about the men's points of view? That is work for the sociologists who have nothing else to do but wonder what the other fellow is thinking about. Cartoonist Briggs frequently illustrates this.

Reading the railway journals—That may be all right for college graduates and others who are attempting to pick up the railroad mechanical trade. But what can a man who has succeeded in advancing himself to the position of foreman in a railroad shop by his own unaided efforts learn from them that he does not already know from actual experience? The writer has bundles of them not yet out of their wrappers, having no time to read them. And as for the advertising pages being an education, whoever yet saw the machine that would do all the advertising claimed for it?

Treatment of new employees—What is the employment office for? If it sends in one who can't "cut the buck," I say, "chase him" and then tell the employment manager what you want and holler until you get it. About 20 minutes is all I want to size up a man and decide if he will do.

New tools and machinery—You never get the ones you ask for anyway, so why bother? Let the purchasing department look after it. Many of the new machines are no better than some of the old ones. I believe in making the old tools last as long as possible. Just keep them in repair. Much can be accomplished in this way without always whining about new tools.

Sales engineers—There most certainly are shops where salesmen cannot enter and mine is one of them. These guys, if you listen to them, would tell you to scrap some of your best tools. They are always trying to get your goat by some wild story of how much quicker work is being done on some other road than in your own shop, but it is generally a long distance away and hard to prove. They are out to sell goods, not to look after the railway's interests. So why waste your time with them?

Conservation of material—I think the reclamation department one of the most important things in connection with a railroad shop and it should be supported by all departments. Why spend time as suggested by Bill Brown by having his men attempt to use material that should rightfully be first passed through that department. If you drop a 1-in. nut into the pit, use another and let the other go on through the process of getting into and out of the regular salvaging department. It would probably cost more to get into the pit after it than a new one would.

Relationship to the foremen of other departments—More Sunday School stuff. While I would not be delighted, as Bill says, to see the other fellow get into a hole, yet I would most certainly be delighted to have my department ahead of all the other fellows' all the time, if possible. Competition is what peps up all departments. Let the unfit get into the hole and the foreman who is habitually behind take his medicine and make room for another. Getting together and protecting the misfits will not get the organization, as a whole, anywhere. If he can only bat 100, why try to protect him? A foreman can keep quite busy looking after his own department without troubling about the others. I believe in leaving such matters for the shop superintendent or master mechanic to take care of.

Attitude toward apprentices—Well, the "Rev." Bill Brown (which is not his real name or I would not say this) in my opinion is no man for a modern railroad shop and I doubt very much if he will last long wherever he is. No wonder he did not wish his real location revealed. He is altogether too visionary. No doubt he is also an advocate of "The League of Nations." If there is any one class of shop employees that should be treated rough, I'll say it is the apprentices. Let them know from the start who is boss and what they are up against and do not permit the slightest deviation. The rougher you treat them, the better they'll like you when they are through. The picture of "Rev. Bill" surrounded by 20 of his bright boys with a 24-in. vernier in a railroad shop of today is almost overcoming. Who ever heard of a vernier in a railroad shop?

He possibly can get away with his methods for a while. But I am afraid he will eventually be out selling hymn books instead of trying to run a department in a present-day locomotive repair shop, where the routing schedule of his department, supply of materials, heavy cuts and coarse feeds are the subjects that should be uppermost in his mind.

I do not suppose you will care to publish this, but it is at least an acceptance of your suggestion and the way the writer views your first prize article; I am wondering just what some of the others were like, since it got first place. Possibly it was the only entry.

"Top Sergeant."

A follow-up on "Bill Brown"

To the Editor:

Bill Brown said a mouthful!

This, therefore, is not a criticism of his article but rather to augment it. Brown of necessity had to cover a large territory in a few words and naturally could not stress any particular points.

As an ex-supervisor, the responsibilities of the foreman, his location in the organization and his duties always impressed me greatly.

It has been truthfully said that the foreman is the key man in industry. On his resourcefulness depends: Production, costs, co-operation of employees, and interpretation of the policy of the company.

The foreman who can get the maximum production at the minimum cost has the co-operation of the employees and it is obvious is correctly interpreting the business policy.

No amount of assistance from those higher up can or should relieve the foreman of responsibility for the four cardinal points above mentioned. He must synchronize his men, his machinery and his materials; he must have a clear understanding of the problems confronting his men and a definite knowledge of the sound principles and methods of industry. Upon his training, or lack of it, depends the success of his department and as his department is an important unit in the entire organization, the success of the railroad is likewise enhanced or jeopardized.

Keeping posted

That part of Bill Brown's article pertaining to keeping posted is well taken. The greatest problem the foreman is up against is to keep up-to-date. The various railroad magazines and correspondence schools are excellent medium of information and every foreman should be encouraged to study.

It would indeed be Utopia if foremen were given a day off now and then to visit another shop, but what road makes a practice of this? The general foreman, master

mechanic and shop superintendent have this opportunity in their membership in various railroad associations, but the ambitious shop or gang foreman does not, as a rule, have this chance. He must study to gain additional knowledge and unless he is more or less of a student he does not progress very far. Unfortunately the average foreman does not avail himself of the opportunity of study and as a result "carries on" in a manner almost identical to his predecessor which does not make for progress in the railway industry.

Another opportunity of gaining information which is seldom granted the shop foreman is to talk to the salesmen or as "Bill" calls them, the sales engineers. The master mechanic will invariably prohibit the salesman from entering the shop and talking to the foreman and perhaps the sales people are responsible. If, upon being granted permission to talk to the foreman, they would confine themselves to business, there is no question but what the interview would be of mutual advantage to all concerned.

The writer heartily suggests that one of the best mediums of gaining information is for the foreman to join some railway club. An excellent paper is read at each meeting and in addition to this he will have the opportunity of meeting foremen who are employed on other roads.

At a recent regular monthly meeting of the Western Railway Club there were over 400 railroaders and railway supply men present.

So much for keeping posted!

Sizing up men

A foreman, to be highly successful, must be a judge of human nature. Brown suggests that upon promotion the new foreman should call his men together and assure them of his co-operation and request their hearty co-operation. Splendid, but for various reasons, as stated by Brown, such as jealousy over the success of others, there will be one or two men of the gang who will say "bunk" and unless immediately curbed, will and can do considerable damage to the production program. These "kickers," frequently the best men in the gang, can be lined up, if the foreman is a good judge of human nature.

One type can be handled by approbation. Slap him on the back, tell him what a good fellow he is and instead of orders, suggest, and before long this fellow will believe the boss is a "regular guy."

A second type delivers best by constant hammering. The new boss must get this fellow to one side and very frankly say: "Jim, you are not working with me. Without your co-operation the department will fall behind and if it falls behind, one of us is going to get fired and my being the boss, it goes without saying who that one will be." I'll bet Bill Brown has bumped into that type and has handled him in a manner somewhat similar to the one just referred to.

A good foreman knows that each individual has his distinct characteristics, his peculiar likes and dislikes and he has the good sense and common courtesy to treat each man as an individual. He knows that each person has emotions, instinct and temperament and that the best results can be obtained by applying individual treatment to each man under his jurisdiction.

Do not employ a man by sizing up the clothes he wears or his manner of speech. Size him up as a potential supervisor and if in your opinion he can qualify, put him to work.

Do not be afraid of your man getting your job. By his strength and ability to perform, your own job is strengthened and your opportunities of advancement are enhanced.

If there is a more pitiful sight than the man who is always afraid some one is going to get his job, I'd like to know it.

Interpreting company policies

Bill missed a point which I shall designate "interpretation of policy of the company." The difference in operation of a railroad shop and that of a manufacturing plant, insofar as policy is concerned, has always struck me forcibly. In the manufacturing game we know the whys and wherefores. An order is usually supplemented by an explanation of the reasons. The railroad game is of a military form so far as orders are concerned, the big idea being "do it and ask no questions." This operates adversely in two ways. The foreman, without a proper understanding as to the reasons for a certain move, usually becomes militant and balky on the one hand, and, on the other, he loses initiative and feels that a suggestion on his part is decidedly out of place.

The point I am trying to make is that the foreman becomes a mere automaton and performs without consciousness.

Along this line of thought, it is my belief that the foreman should at all times be aware of the reasons for a drastic change in policy. Is it because business is poor that he must cut off his men and use scrap and second-hand material, or is it because a surplus is desired that a general plan of economy may be established?

What a mistake costs

And another thought! The foreman is not taught to think in money terms, as he should be. He should know that instead of Jim Jones spoiling a driving brass by improper machining and treating this as an article, Jim has cost the company so much in labor and material. This thought should permeate all through the railroad. Instead of saying to a car inspector: "Sam, you let XYZ-6000 get by with a defective carrier iron and she dropped a drawbar at Grand Junction causing a derailment," you should say: "Sam, do you know that through your failure to detect a defective carrier iron on XYZ-6000 you have cost the company $375?" Money means something to everyone and if he can get your point of view—that by carelessness he caused a damage equal to two month's pay—you surely have gained a point!

If a machine-hand realized that the machine he was operating cost several thousands of dollars, don't you believe he would treat it better!

If a pipe man realized that by scrapping a valve the company stood a loss of eight or ten dollars and that he could repair this valve in one-half hour, he certainly would stop and think?

All of which leads to the point that the master mechanic should equip his supervisors with price lists on all materials and equipment in order that they may have a better idea as to where money may be saved.

An industrial authority has stated that sixty per cent of strikes are due to bad foremanship. This does not apply to the railroads, but there is no doubt but what the foreman could engender a closer relationship between employer and employee if he were fully aware of the "Why and wherefore."

There was a time when the title of foreman was sufficient to command obedience and respect. The foreman of today must prove himself worthy and capable of leadership, in thought as well as in deed.

An Ex-Railroad Supervisor.

Supports "Bill Brown" arguments

TO THE EDITOR:

Bill Brown in his prize article on "The Foreman and his Responsibility" commences by quoting two of his experiences as a mechanic. Not as a rebuttal, but in a spirit of fairness, I want to tell you something of my experiences as a foreman.

Bill Smith, erecting foreman, wanted a steam chest cover planed for clearance, explaining that he wanted to get the engine off his hands because it was blocking the schedule. Also he was short-handed through absentees and I could plane it quicker than he could set up the pressure plate. I agreed with him since we had more to lose by delaying, and so he sent it over to the planer. Shortly afterward Bill Smith came back and the following conversation took place:

"Have you no authority over your men?" he said. "Jack Jones says he will not plane that cover."

"Well! There must be some mistake. I will go over and see about it."

"Say, Jack," I said, "put this cover up and plane it. It is the only job holding the engine."

"Nothing doing on that job!"

"What is the matter? This cover has to be planed and this is the best machine for doing it."

"All right. But it won't be planed by me. If I have to be fired, it will be for not doing it, as Mr. S——, the master mechanic, told me he would fire me if I planed any more."

This was the first intimation the writer had of a hard-and-fast rule against this practice.

Another time I had occasion to criticize one of the men for neglecting part of his work. The man did not take kindly to this criticism and went to the master mechanic with his grievance, to which the writer did not object in the least.

The following conversation afterwards took place between the master mechanic and writer:

"Did you fire Jack Jones?" said the master mechanic.

"No, sir. I did not."

"All right then. I thought that if you had I would try to place him in another department."

This, too, without an investigation.

What I am trying to tell Bill Brown by these experiences is that to make a foreman realize his responsibility, he must first be given that authority that makes him responsible.

Keeping posted on railroad affairs—I don't believe a foreman in these days of industrial progress can hold his job very long without reading one or more of our mechanical journals, but I don't altogether agree with Bill Brown when he says it is up to a foreman to explain why short hours are necessary, and also about the operating ratios, taxation, rates, etc. Too often, out of a clear sky, a notice is posted in the shop or roundhouse calling for a reduction of hours without any explanation at all. In these days of shop committees, the necessity for this should be explained to them, or the posted notice be made explanatory. Some of our larger railroads are now publishing weekly or monthly magazines. It would make good reading if this information was published in such magazines or bulletins.

Treatment of new employees—Bill Brown has opened up lots of room for thought in his comments on this subject. Too many of us look on a man as a means of production alone, forgetting altogether the human side. I well remember a certain foreman going after a machine man for not turning out as many pieces as he did the day before. That man's wife had that day been taken to the hospital for a serious operation (later she died), and although he knew he should not have been at work, he could not afford financially to lay off. That one instance alone taught me that it did not hurt me one bit to be sociable and that I would not lose any so-called prestige by inquiring about a man's family; in other words, showing that I was interested in other things besides production.

A new man should be made acquainted with his job, and if his job is running a machine, he should be given all the information at the disposal of the foreman about maintenance, production, etc. Pictures, set-ups and time studies can usually be had for the asking from the machine makers or salesmen. Too often we find this literature locked up in the foreman's desk. The writer believes in specialization. Train a man to be efficient in the work allotted to him. Explain what delays mean through underproduction or slack work. Make him feel that that part of the locomotive or car on which he is working is his responsibility and if the part fails, we all fail. In other words, sell him his job.

New machinery—A foreman should be, at any time prepared to show what saving he can make by the installation of new machinery or tools. Sometimes we have difficulty with a job that is only repeated occasionally; on looking through a mechanical journal, we may find that a manufacturer has a machine or device on the market for this work. Naturally, we want it and are apt to lose sight of the fact that the interest on the money spent for this device would more than pay for the time lost by the method now in use.

Foreman's relationship to other departments—Bill Brown's comments on this subject surely hit the spot. The opportunities for the display of inter-department teamwork are truly unlimited. The writer has attended foremen's meetings and noticed the satisfied look on some faces, knowing that their particular department is up to schedule and seemingly not interested in the least in the other fellow being behind. The success of the whole shop or division depends on the weakest link. Your own department may be 100 per cent, but if the rest are only 50 per cent, that will be your shop's rating.

A closer relationship between foremen socially would be beneficial, no matter if it be through organization or arrangement. Representatives of the management can assist greatly in this by attending the meetings, thereby showing that their interest is not confined solely to output. They could also arrange for talks from equipment salesmen, safety men, etc. Roundhouse and backshop foremen should both attend the same meetings. A little friendly discussion of their habitual differences does more good than a lot of letters from the master mechanic and also leaves a better taste in the mouth. If we cannot co-operate among ourselves, how can we expect it from our men?

Times and conditions are changing the relationship between foremen and men so fast that it is difficult for a foreman, trained along the old lines, to change his methods and to realize that maximum service does not depend on him alone, but on the co-operation of every man under him. Let the officers boost the foreman's clubs and organizations by attending themselves or supplying a speaker once in a while to speak at some of the meetings.

A year or so ago one of our large universities sent out a man to deliver a series of lectures to foremen in the city I happened to be in. These lectures opened up an entirely new line of procedure in the handling of men and I

am sure that all foremen that attended derived great benefit from them.

Attitude toward apprentices—I am going to make a broad statement and say that in a modern railroad shop, of say 200 or more men, an apprentice has no place unless a competent instructor is employed. It is not fair to the apprentice or to the foreman to expect him to take an untrained boy and make a mechanic out of him. In the shop where the writer served his apprenticeship, each boy was examined every month as to his ability in the department he was working in and was kept there until fully competent, there being no set length of time in any department. As an inducement to learn and to get through each department quickly, he was given a show in the tool room or on special work and, when possible, given the place of a gang boss. I would like to ask Bill Brown if he happened to have a rush of work and had an apprentice fully competent to handle his share of it, would he transfer him and train another or keep him until the rush was over?

Responsibilities to officers and men—A foreman should never lose sight of the fact that his are the eyes through which the officers see his men and through the same eyes the men see the officers. A foreman, to a certain extent, stands to his men in the same light as a father to his sons. He cannot afford to lose their respect. A slip on his part often results in the loss of morale of his whole department.

In all cases, apply the Golden Rule and your whole department will benefit. "OUTPUT."

The foreman and his responsibility

Second prize article* in the competition held by the Railway Mechanical Engineer

By John H. Linn

Assistant supervisor of apprentices, Atchison, Topeka & Santa Fe

THE foreman occupies a strategic position in a railway organization. He has a vital part in the cost of production and of operation and in building up a loyal, efficient organization. He is responsible not only for the proper care and maximum output of the mechanical equipment of his shop, but also for the placement and maximum effort of each man in his charge and for the proper correlation of the work of the various gangs so as to produce the highest efficiency of the department as a whole. Upon his shoulders rests the responsibility not only for the immediate output of his department but also for the building up of an organization which will determine the output in years to come.

The foreman is the connecting link between the management and the men. He is the representative with whom the rank-and-file come in closest contact. He embodies to them the corporation. He is the company's man. If he is fair and considerate and his example such as to command their respect, it will be easy to create in the men a feeling of loyalty toward the company and of willing co-operation with the management as a whole. But if he is grouchy or ill-tempered or self-centered, or guilty of showing undeserved favoritism, the ill feeling engendered will in all probability extend to the corporation which he represents. The foreman, being in direct contact with the men, is the interpreter of company policies. As such he has a great opportunity for instilling loyalty in the men and for building up the desired morale among the working forces, without which efficient results cannot be secured.

Essentials of successful management

The five essential factors in modern industrial management, whether in railway management or in other industries, are money, materials, machinery, methods, and men. The foreman enters into every one of these factors and is vitally responsible for the solution of the problems involved in each.

Although not directly called upon to provide the capital with which to finance the plant, the foreman in any industry is largely responsible for the amount of money needed, and the ease with which it is secured. If he is wasteful and extravagant, more money will be needed. If the output of his shop is insufficient, it will be difficult to raise the necessary funds to keep the shop going or to enlarge its operations.

The financial responsibilities of the foreman are even more apparent in a railway shop than in an industrial plant. The public is demanding not only more efficient transportation but also that the cost of transportation be lowered. Freight rates cannot be lowered unless costs are reduced. There can be no reduction in cost of materials or needed facilities; neither is it desired to reduce wages. There remains but one solution, and that is to increase the efficiency of the railroad organization and thereby lessen the cost of operation and of maintenance. This cannot be done without the co-operation of the railway foremen. Upon their capacity for organizing their forces, their ability to obtain maximum output from the men in their charge, depends the solution of this problem.

Materials and machinery

Closely related to this heavy responsibility resting upon the shoulders of the railway foreman, is his responsibility for the materials and machinery used in his shop or department. The successful foreman must know the quality of the material he uses, the purpose for which it is to be used, and its fitness for that particular purpose. He must be familiar with the cost of materials and equipment—the original cost, the cost of storing and handling, the cost of deterioration due to exposure, the cost of breakage and of spoiled work, the cost of using more material than the job requires, of using expensive material when an inferior grade would answer, and of the false economy of using inferior material when a better grade is demanded,

*The First Prize Article was published in the June issue, page 360. Criticisms and comments on it will be found elsewhere in this number.

the cost of surplus material becoming obsolete, the cost of his lack of foresight in not having material on hand when needed, the cost of handling materials and the added cost of inefficient methods of handling. The foreman has a great responsibility in keeping all such costs to the minimum. He must know, too, the cost of power, the cost of installation, operation, and maintenance. He should understand the operating cost—when it is advisable to speed up and when to slow down on the time of operation. The foreman is in a large measure responsible for the cost of operation. This cost is largely affected by his ability to handle questions of repairs and replacements, by machines being overloaded or underloaded, of being run too fast or too slow, by machines being idle, by the work of one machine being held up awaiting the output of another machine or department.

As to planning the work

Too much cannot be said about the foreman's responsibility for so planning his work and so co-operating with other departments as to produce maximum output for the department as a whole. The successful foreman must keep in touch with improvements constantly being made in equipment and must make full use of modern up-to-date machines and mechanical devices. He must be aware of the cost of obsolete equipment and of poor layout of equipment, of machines not being conveniently arranged, or of insufficient working space or of certain kinds of work being too widely scattered. His mistakes, whether of commission or omission, are indeed most costly to the railroad.

He is largely responsible for the methods used in his shop. He must know what methods to use, when to use them and how to adapt these methods to the needs of his shop and to the men. It is not the purpose of this article to discuss any particular method; suffice it to say that the foreman has a great responsibility and a great opportunity in deciding on what methods should be used in his department.

Foreman's greatest responsibility

We have mentioned briefly the foreman's financial responsibility, his responsibility in connection with materials, machinery, and methods, but it is in his relationship to his men that his greatest responsibility lies. The amount paid for labor is the biggest bill the railroads have to pay. No part of a foreman's duties are more important than that relating to the human element. No official of a railway organization has more to do with the man-power of the organization than does the foreman, from whom the men take their orders, receive their instructions, and learn of the aims and purposes of the management. No field of railroading offers greater opportunity for effective results than that relating to the man problem. Herein lies the foreman's greatest and most far reaching responsibility and opportunity. As Herbert Hoover says in speaking of our railways "We have devoted ourselves for many years to the intensive improvement of machinery and processes of production. We have neglected the broader, human development and satisfactions of life of employees that lead to greater ability, creative interest and co-operation in production. It is in the stimulation of these values that we can lift industry to its highest state of productivity, that we can place the human factor upon the plane of perfection reached by our mechanical processes." It is upon the shoulders of the foreman that the greatest part of this responsibility must be placed.

There must be greater care in the selection, placement, and training of workmen. In railroading, as in other lines of industry, more systematic methods must be employed to improve skill and to prevent men of talent from being side-tracked in blind alleys, to prevent incompetent, untrained men from being placed in responsible positions; in brief, to prevent the deplorable, and to a large extent, preventable waste, due to human inefficiency. Except where a well-organized training department has been provided, this responsibility rests almost wholly with the foreman. He it is who selects the men; he it is who places them in the shop and assigns their work. From him they receive their instructions and training and promotion. Even where a well-organized training department exists, much of the success accomplished is due to the co-operation and assistance from the foremen of that department.

The foreman must not only "know his stuff" but must know how to impart his knowledge to others. He is, after all, a teacher, a general. He must be a student of nature, must know how to lead and guide others, how to administer discipline, and how to inspire enthusiasm and whole-hearted co-operation. It is well that the foreman have skill in the work of the men he is to supervise. Others may "pass the buck" and depend on some one else for information needed, but the foreman must know whereof he speaks. He must be able to show by example how the job should be done. Having been through the mill and regular grind himself he can better sympathize with his men and understand their problems. Being a first-class workman, able to deliver the goods himself, he can better command respect and obedience from the men in his charge, can more intelligently issue orders and offer suggestions as to methods of performing work, and can intelligently pass judgment as to quality and quantity of work performed. Truly the foreman possesses unlimited responsibility. But more important than the responsibility placed upon the foreman in the requirement that he have knowledge of the work he supervises is the responsibility resting upon him in knowing how to keep the work moving from the rough to the finished job, and the responsibility resting upon him in properly managing the men who are under him.

The wrong kind of foreman

Nothing is worse for a company, nor the men employed by it, than unrestrained power in the hands of a passionate, narrow-minded man. A foreman with a quick temper and a sharp tongue who thinks more of showing his authority than of getting the work out, who makes no effort to keep his men satisfied or to inspire them to the best that is in them, can sow more discord in a minute than the most diplomatic manager can eradicate in a year. An incompetent foreman keeps the shop in a turmoil and the workmen irritated. Not knowing how to keep the work going systematically, he complains and scatters blame around when he alone is the culprit.

No matter what a foreman's other qualifications may be, his influence will be bad if he is not honest, courteous, considerate, and of good habits. In disciplining, a foreman must never forget that his men are human beings with just as much self-respect, as much pride, as much manhood, and as much "touchiness" as he himself possesses. To be placed in a position to pass judgment or administer discipline gives one no right to do it harshly. Workmen know when there is kindness behind the discipline meted out to them. A reprimand may make or sour a man. A merited calling down, administered in the right spirit will be far more effective than an ill-tempered "bawling out."

After all, as was said by the late President Smith of the New York Central: "It is not the powerful modern steam locomotives, or the still more powerful electric motors, or the endless chains of freight and passenger cars, or the well-appointed terminals, or the solidly laid tracks, or the intricate signal system; it is not all this elab-

orate net-work of equipment that makes the railroad wheels go around 24 hours of every day of the year, it is the human heart beat. Unless the great majority of those constituting the organization are working in harmony and working heartily, the results can only be disappointing."

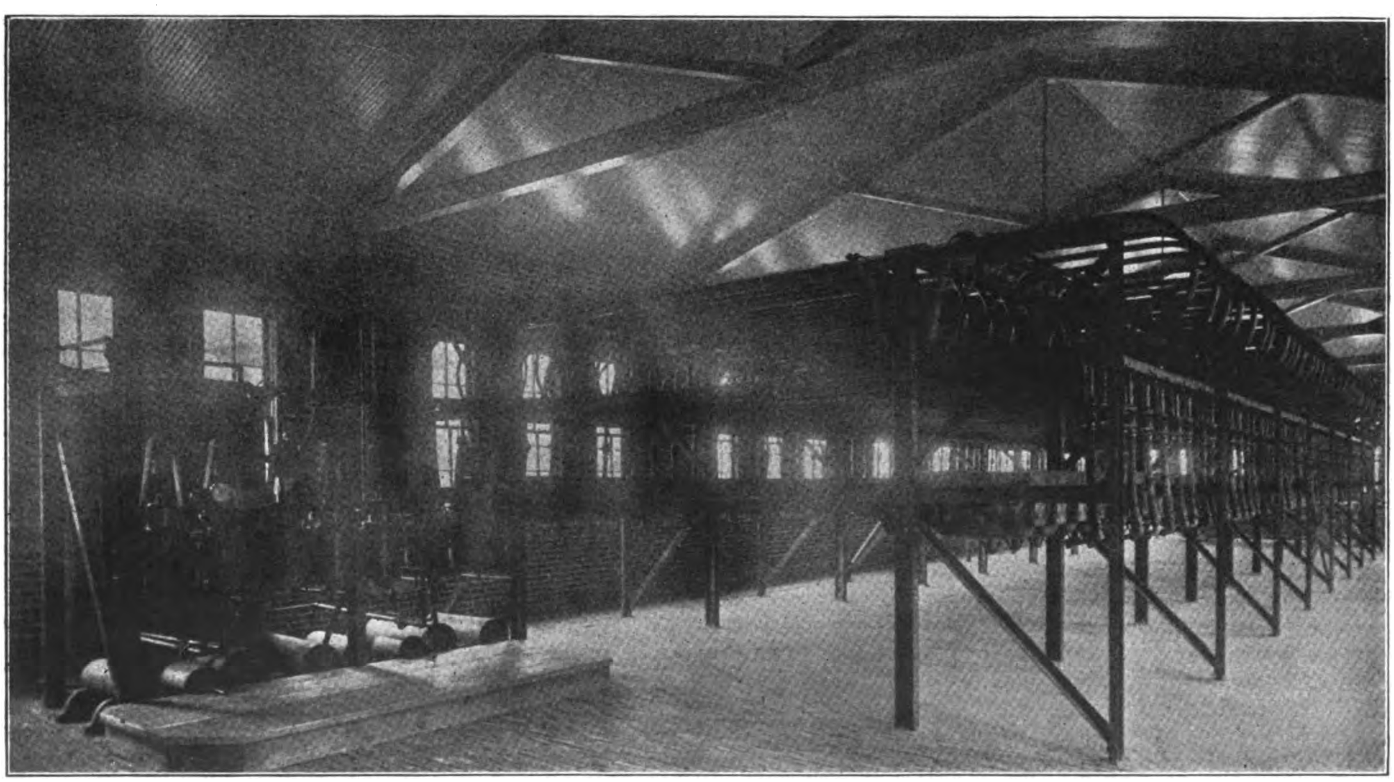
It is the duty of the foreman to bring about this harmony of effort on the part of his men. Without this co-operation, maximum results cannot be achieved. Again we repeat, the responsibility resting with the foreman is exceedingly great.

Have an understudy

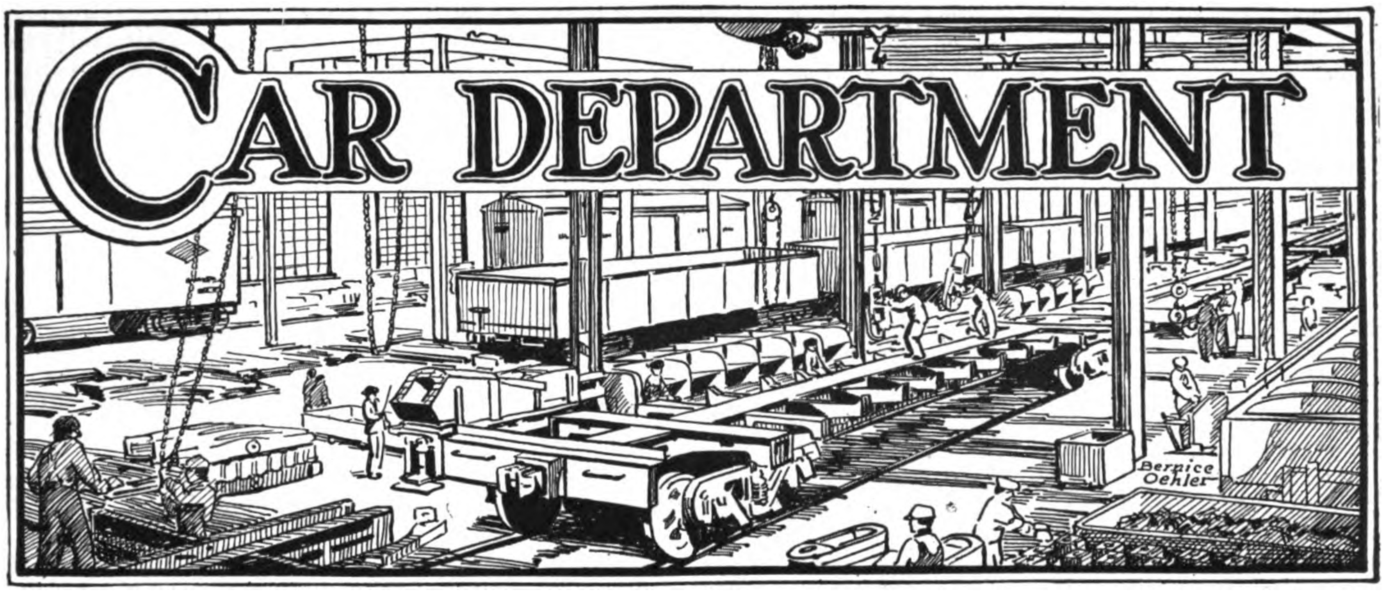
One other responsibility resting with the foreman should be mentioned and that is his responsibility for having someone under him trained and ready to take his place. He should take a competent, carefully selected man under his wing and personally train him to follow in his footsteps, giving him the benefit of his experience and giving him a chance as opportunity offers to try out and develop his ability, not only in the absence of the regular foreman, but at other times when the successful foreman is at hand to note and correct his mistakes, giving him an opportunity to profit by the lessons others have learned but leaving him sufficient freedom to use his own originality and initiative. A foreman who is so narrow minded and selfish that he is unwilling to give an understudy full opportunity for development, fearful that he himself may be surpassed in promotions, is himself unworthy of promotion and the sooner he is relegated to the discard, the better for all concerned. If each foreman will see to it that he has someone ready to take his place, the problem of securing competent supervision, which causes trouble in many shops, will be solved.

We repeat, the foreman occupies a strategic place in a railway organization. Upon his success or failure the whole organization depends. They are the men who get results. From them, the future executives of the railway will be chosen. Upon their shoulders rest the output and loyalty of the rank-and-file. To their sympathy and understanding of their men and their everyday problems, their understanding of and ability to carry out the aims and policies of the management, their ability to produce immediate output and to build for the future, the efficiency of our transportation system must be attributed. Truly a railway foreman has a great responsibility and a great opportunity.

Illinois Central rules for storing coal.—The Illinois Central has issued rules governing the unloading and caring for storage coal. The ground upon which coal is to be stored must be firm, level, clean and properly drained, although no drainage should pass through or under the storage coal piles. Coal, which is unloaded into storage should not be placed on loose cinders, against wooden posts, wooden trestle bents or hot or warm pipes or flues; nor should it be placed in piles to exceed 12 ft. in height and 36 ft. in width at ground level, with the piles limited to 1,500 tons, and spaced with intervening distances of at least 5 ft. The piles must not be ventilated by artificial methods. Coal of different sizes should be placed in separate units and this same practice of segregation holds true when unloading coal of same size from different mines. Coal should not be dropped from the grab buckets more than 3 ft. The coal should not be moved after once being placed in storage, unless absolutely necessary. The temperature of the coal should be taken at least once each week, and oftener if possible, using either the thermometer or rod method; and when coal is stored under cover, the structure should be well ventilated to afford outlet for gases. Under no circumstances should water be applied to a heated coal pile. Heated or burning coal should be removed and used, or extinguished by scattering and then applying water.



The air brake rack at Purdue University comprises equipment for two locomotives and 148 freight cars—A chronograph for recording the time of application of the brakes is also included in this equipment.



How to stop hot box epidemics*

Regular reports will show where the trouble originates and a personal investigation of causes should follow

By A. M. Orr
Bessemer & Lake Erie, Greenville, Pa.

IN discussing the problem, "How to stop hot box epidemics," it will be assumed that proper material has been supplied to the oiling and repair forces, and that they have been so trained that the hot box record has been satisfactory in the past. This being assumed, it is unnecessary to discuss any of the details of the proper handling of packing and oiling.

The problem seems to divide itself into the following minor problems:

1—How are we to know that a hot box epidemic is upon us?
2—What is the probable cause?
3—What repair point or division is responsible?
4—What action is necessary?

It is probable that on every road there is a system of reporting a car which has been set out of a train before reaching its destination. That report is made, as a rule, by wire to the chief dispatcher. If the report does not already contain that information, it will be easy to change it to show the point where the car was picked up, and the fact that it has been set off for a hot box. A copy of each of these defective car reports should be furnished to the master car builder daily. In his office the reports should be classified as to the point of origin of the car. When reports come to the master car builder's desk, he will be able to tell at a glance whether any repair point is chargeable with more than its usual number of hot boxes. Thus, immediate knowledge is furnished to the head of the department concerned of any increase in hot boxes.

It is not worth while to try to itemize the probable causes of hot box epidemics, for they will be precisely the same causes which are daily causing individual cases. There are, however, certain general suggestions which can be made. If there is a sudden jump in the number of hot boxes on the morning report, and if those hot boxes all come from one station or district, it is probable that the trouble is a local one. More especially will this inference be true if the increase in hot boxes has been gradual, and chargeable to one station or district. If, on the contrary, the increase is relatively sudden and all, or nearly all stations are involved, then the cause is not local. Keeping this subdivision in mind, it is sometimes possible to determine very quickly what the trouble is.

Should the trouble be general, and in the fall or spring of the year, one may stop the trouble in 36 hours by arranging for a supply of oil which suits the weather conditions, a cause not always given as much attention as it should have. Or perhaps a visit to the stores department waste storage may disclose a supply of waste which has not the necessary capillarity.

If, on the contrary, the attack is very sudden and very sharply defined as to origin, one may by inquiry find that a lot of foreign cars have come on the road for loading, or that some home cars which have been stored for a long time have been moved forward for loading without having been given preliminary attention to insure that the journal packing is in good condition.

As a general rule if the increase is relatively slow and local, look for disorganization of repair force or local trouble with material; if the increase is sudden and wide spread, look for a special trouble, first of all in quality and handling of oil, waste and bearings.

If the report already suggested has been kept up daily, there is an immediate answer to the question "What repair point is responsible?" if the increase is sudden and local, but hot box epidemics which come from poor material may be several weeks developing. This will be true, for example if the quality of journal bearings fur-

*A paper submitted in the competition on hot box prevention.

nished has changed for the worse. It may be several months before the full effect of such a change will be manifest.

It is desirable, therefore, to have a historical report which will cover considerable periods of time. One such report may be made weekly in the simplest possible form. It is not to locate responsibility, it is only to point out tendencies. If for example, a report is made which shows weekly the number of hot boxes on east and west bound traffic, or on traffic from certain special loading districts, that report will call attention in a general way to general will show general tendencies. If such a report is made, it is important that the master car builder or his travelling car inspector shall, by personal instruction, make sure that all repair points are using the same method for determining what a hot box is, for if there is not such a general practice, some stations may be reporting as hot boxes some which others would not. It is not usually practicable to determine the point of origin of hot boxes on cars which are carried through to a terminal, nor is it really necessary, for experience shows that the relative mileage based on cars set out, and the mileage based on total hot boxes will

Summary statement showing total hot boxes by months and comparative mileage figures

increases which might be overlooked on the daily reports because of the gradual increase.

The real historical report should be monthly, and it should go into details. It is desirable, first of all to know how many hot boxes caused real trouble; that is, caused cars to be set off en route. It is these hot boxes that block the tracks to traffic while the cars are being set off and being picked up, that are responsible for the breaking of couplers while heavy trains are trying to shove a car into a siding and that cause large expense for repairmen not vary more than perhaps 10 per cent, unless the transportation department has taken a special interest in the hot box question and has managed to get the conductors interested in taking cars through to terminals rather than to set them off. Such special attention, while the new standard of mileage is being established by the conductors will throw the relative values off for a while.

One road, by working steadily with the train masters, was able to get conductors interested in applying grease to hot journals, looking after them in a general way while

Example of report of hot boxes originating at different stations

who have to go out on the road to repair them at non-repair points.

It is also desirable that these hot boxes be accumulated monthly as to responsible stations, so that the tendencies at those individual stations may be observed in a general way. A repair point may gradually crawl up from 10 or 12 hot boxes per month to many times that number without attracting special attention on the daily reports. The monthly report shows that increase clearly.

If the report includes also a statement covering not only the hot boxes set out en route but also those found at terminals, there will be an additional measuring stick which waiting at meeting points until the mileage per car set off increased from 8,702 miles to 39,073 miles four years later.

It is because of the possibility of such fluctuations that it is best to use the total hot box record as an indicator. The actual figure used will, of course, be some function of service. The loaded car mileage is desirable in some ways, for it is most productive of hot boxes, but it is well generally to use the total transportation freight car mileage.

That figure will vary on different roads. A road of light equipment may show a high mileage per hot box while a road of high speed heavy traffic may show a low

mileage per hot box. The figures of one division will vary from another. As with most other railroad statistics, they should be always used with caution as relative figures, showing tendencies.

What action can be taken to stop the hot box epidemic? It will be noted that the measures suggested are mostly indirect and preventive. It is necessary to see that the materials supplied are of such quality that under favorable conditions there will be a good bearing upon a journal which is perfectly smooth, against which presses a packing of proper texture to feed an oil of sufficient quality to maintain a film of .003 in. between the journal and the bearing.

But as in every other situation, and more so than in some, the real controlling factor is the human one. Starting with the daily report, let it be the routine practice for the master car builder or his travelling car inspector to make a personal visit to or talk with, by 'phone, every foreman whose station has increased its usual hot box debit for the previous 24 hours. This seems quite a job, but if it becomes evident to the men on the job that a personal explanation will be called for every time the hot boxes increase, there will come the feeling, "Guess it will be well to see that cars are right when they go out." The written letter or memo will never take the place of the personal visit. It is important that the men higher up keep in mind that it is not a question of a "bawling out." The greater part of the time the cause of the hot box was not the fault of any single individual. The attitude should be taken that what is wanted is information. After this practice has been carried on long enough, there will be a steady flow of information on the subject. A distant foreman will report that brasses shipped to him arrived with linings loosened from the back or scored and full of grit and sand. That involves the crew of the local freight perhaps: but it is not a case of trouble for them. Very likely they look upon brasses as pieces of metal to be handled with as little care as brake shoes. A word of friendly explanation may remove that trouble instantaneously and forever.

Next may come one of the men from the receiving department of the store room. He has learned from similar suggestions that waste is not something to wipe machinery with when the car department is concerned, but a medium of transmitting oil to a journal. He has a sample of new waste which makes him suspicious. What does the M. C. B. think of it? Psychology teaches us that we can many times increase the productivity of human labor by affording a point of interest to the worker. Properly handled, this system will provide that point of interest.

When the preventive work has failed, and when the hot boxes increase, then it is necessary to consider the problem, and it can only be handled on the ground. The man who is bucking that problem is the same as the wreckmaster. He must go to the source of the trouble, which he knows from his daily report. What he will find there may be anything that will make a hot box. He must work right with the oilers, he must ride the trains himself and work with the hot boxes which develop to see just what the trouble is. If the trouble lies with a supply of below-grade bearings which have been gradually applied over a considerable time he may have a long job, or it may be that 24 hours work will end the trouble.

The valuable thing about such a system is that it practically stops anything which can be called a hot box epidemic. After the lapse of sufficient time, nearly every man on the road will be interested in keeping down that hot box record, especially if the monthly tendency report is carried on a blue print or mimeograph sheet so that cumulative figures for the year are shown. A copy should be sent monthly without comment, to each repair point.

Mileage figures as already suggested are very delusive when used as means of comparison, so that actual mileage figures will not be stated. But it seems reasonable to affirm that any road which does not have such a close personal check on the hot box problem, regardless of how good its figures look, may expect an improvement of at least 50 per cent in the number of miles per hot box within two years after commencing such a system, besides the immediate location of the place responsible for an attack of "hotboxitis."

Decisions of the Arbitration Committee

(The Arbitration Committee of the A.R.A. Mechanical Division is called upon to render decisions on a large number of questions and controversies which are submitted from time to time. As these matters are of interest not only to railroad officers but also to car inspectors and others, the Railway Mechanical Engineer will print abstracts of decisions as rendered.)

Responsibility for damaged car involved in a derailment

An inspection certificate was issued on April 7, 1922, by the Maine Central for Bangor & Aroostook car No. 6228, which was accompanied with a letter dated April 12, 1922, which explained that the cost of repairs exceeded the prescribed allowance under A. R. A. Rule 120. The Maine Central requested the car owner's authority for the certificate and advice as to what disposition was to be made of the car. Authority was given to repair the car and a bill amounting to $349.61 was rendered for the repairs. It later developed that the car was damaged on the Maine Central in switching at which time C. P. car No. 344,353 was derailed. The Bangor & Aroostook stated that the Maine Central requested authority to issue an inspection certificate but did not mention that the car had been damaged in connection with the derailment of C. P. car No. 344,353, nor did it show how the damage to the car occurred as required by A. R. A. Rule 43. The car owner concluded its case by stating that it was wrongly reported under A. R. A. Rule 120 and should have been reported under Rule 112. This contention was based on Interpretation No. 4 of Rule 32, which states that a car damaged in connection with a derailment carries the same responsibility for damage as a car derailed. These facts place the responsibility for the damaged car on the handling line. The Maine Central maintained that the care failed in switching due to its weakened condition.

The Arbitration Committee rendered the following decision: "In view of the derailment of C. P. car No. 344,353, the Maine Central is also responsible for the damage to the Bangor & Aroostook car No. 6228 which occurred in the same accident."—*Case No. 1326, Bangor & Aroostook vs. Maine Central.*

Failure to apply a defect card at interchange

On September 8, 1923, A. C. L. car No. 39620 and on September 11, 1923, S. A. L. car No. 30715 arrived at Laurens, S. C., in a train of the Columbia, Newberry & Laurens, each car with a centrifugal dirt collector missinspection record. The cars were delivered to the ing, which were noted by the car inspector on the original Charleston & Western Carolina with the dirt collectors missing and no defect cars attached as required by A. R. A. Rule 2, paragraph I. The car inspector at Laurens is

a joint inspector for the C. & W. C. and C. N. & L. The C. N. & L. refused to furnish the inspector with any of its defect cards but required him to request all defect cards from its headquarters at Columbia, S. C., a distance of 75 miles, giving the initial and number of the car and the defects in each case. The defect cards are then issued and sent to the inspector. This accounted for the cars being delivered to the C. & W. C. without the defect cards attached as required by the rules. The inspector wrote the C. N. & L. for defect cards to cover these two cars, which were refused on the ground that the cars had gone over the C. & W. C. to Spartanburg, S. C., before the request for defect cards was made. The Charleston & Western Carolina contended that A.R.A. Rule 2 does not provide for any time limit in which to request defect cards and that if the Columbia, Newberry & Laurens had supplied its inspector with a supply of defect cards, so that he could have attached a card to each car before offering it in interchange, as required by Rule 2, the C. N. & L. could not have raised a question. The C. N. & L. claimed that the joint inspector at Laurens failed to note any equipment missing from these cars on arrival at Laurens and as the cars were moved to Spartanburg, S. C. without Rule 4 being complied with, the C. & W. C. should assume the responsibility for the existing defects on the cars.

The Arbitration Committee in rendering its decision stated that, this controversy is due to the evident disregard of Interchange Rules 2 and 4, first paragraphs, which provide for the defect carding of cars at the time and place of interchange. If the cars had delivering line defects, they should have been properly defect carded at the time of interchange.—*Case No.* 1324, *Columbia, Newberry & Laurens vs. Charleston & Western Carolina.*

Passenger car scheduling system

Increases shop output and reduces working force to a minimum—Competent supervision essential for its successful operation

By Joseph Gullage
General foreman, car department, Boston & Maine, Billerica, Mass.

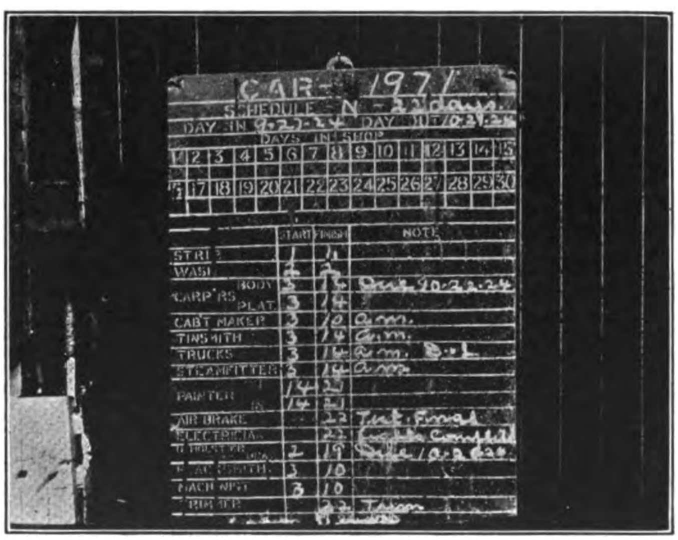
SCHEDULING and routing in railway shops is not new. The first schedules recorded were used in the Chicago & North Western shops in 1904. These consisted simply of working sheets and assigned dates made out and followed up by the shop supervision. Since that time more than 25 railroads have adopted some form of schedule system for repairing cars; all of which are more or less alike in basic principles.

In 1922 at the convention of the Mechanical Division of the American Railway Association at Atlantic City, the Shop Schedule Committee proposed a plan for scheduling cars through the shops. During the latter part of 1922, the Billerica shops of the Boston & Maine put into effect a passenger car scheduling system based on the one proposed by the Mechanical Division committee but modified somewhat to meet the particular conditions at this point. This shop gives general repairs to all types of wooden passenger equipment and the ordinary run of repairs to steel cars. The track capacity of the shop is 60 cars—30 cars in the coach shop and 24 cars in the paint shop—six cars being under wash or paint removal in the latter shop. The output of the heavy and medium repairs is four cars every working day, while the number of light repairs vary. During January of this year, for instance, eight light repair cars were turned out while in February there were 78. However, the monthly average is from 15 to 20 cars.

Points to consider when installing a scheduling system

When installing a scheduling system, there are several items of importance to consider before putting it into effect. If these items are not given considerable thought there is always the liability of the system failing to function properly owing to the lack of proper organization and control.

The first item to consider is the selection of the proper man as the schedule supervisor and to determine the scope of his duties. The man selected for this position should have had wide experience in shop and office work, should be capable of handling men and should have enough engineering practice to make clear reports and records. Preferably this man should have served his apprenticeship as a



Shop bulletin sheet which is displayed on or near one end of each car under repair

car repairman and be more or less familiar with shop production methods. Before putting the scheduling system in force, it is always advisable to send the schedule supervisor to visit various production shops to study the methods used to increase production.

The supervisor's duties should be definitely determined. At this point he is required to digest the inspectors' reports as to the general condition of the cars to be

repaired, on the strength of which the schedule time is set by him for the completion of all the work, subject, of course, to the general foreman's approval. He also has direct charge of the shop inspectors, the receiving yard for crippled cars and the outgoing tracks for repaired cars. foreman makes the final decision in case his decision does not meet with the approval of those concerned. His office provides the reports on shop output and shop conditions. He acts as a sort of a liaison officer between the different foremen on matters pertaining to shop output.

This chart is a summary of the passenger car schedules and is put in this form for the convenience of the schedule supervisor

A yard shifter is assigned to the shops for transfer work, the engine crew of which takes orders from the schedule supervisor. His work also includes decisions as to the standard of workmanship which may be in question between his inspectors and the shop foreman. The general

The location of the office of the schedule supervisor is the next item to be given consideration. This office should be located conveniently with respect to the shops, preferably in the office of the general foreman, which is the case at the Billerica shops. It is important to have this office

so located that the supervision can frequently confer with the schedule supervisor and have ready access to and examine the records on the schedule board.

The master schedule

As each car comes into the yard an inspection of the car and painting is made to determine the class of repairs. The arranging of a schedule depends largely on the longest job on the car, which is usually the paint. It is then good policy to have the painters start their work as soon as possible and arrange to have the other work on the car finished at the same time that the painters start.

The first requirement of the schedule supervisor at Billerica was to plan the master schedule. The schedule, which is shown in the large illustration, is a board upon which is laid down the work to be done on all possible units of equipment used by the B. & M. which come to the Billerica shops for repairs or rehabilitation, from the dining car to the box car carrying a coat of pullman color and the words "Fitted for passenger service," stenciled on its side.

Referring again to the master schedule in the illustration, on the left, will be seen the names of the different paint operations and crafts. The painting operations appear first, which as previously mentioned, determine the length of time the car will be in the shop. For example, it may require as many as 14 paint shop days for a dining car which is made necessary because one coat of paint or varnish must be dry before another can be applied. It is essential to show all the paint operations complete on the master schedule.

The other crafts shown on the board are merely mentioned by name, as a board showing all the various jobs of all the crafts would be one of impossible dimensions and almost out of the question to read.

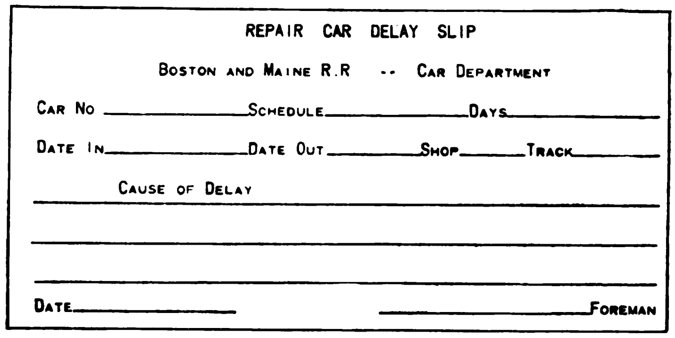
On the top margin of the schedule, at the head of each column, is a row of letters A, B, C, and so on up to N. Immediately above these letters are figures running from 9 to 37. The letters indicates the type of car and the class of repairs and the amount of paint work necessary for each car, while the numbers indicate the total days required to perform this work and the total days the car is in the shop.

How the master schedule is used

To make clear to the reader the application of this schedule to a particular class of work, we will follow a car through the shop according to schedule *M* on the master schedule. This schedule calls for 37 shop days in which time a vestibule passenger coach will receive a steel underframe, the vestibule will be reconstructed and the outside body paint removed and reapplied. On Day 1, the strippers strip the car and distribute the various parts to the proper departments for repair. At this point it is well to mention that the departments are informed as to when they should have the parts for which they are responsible repaired and back to the shop in time to be reapplied in the car. This time is flexible insomuch that each department can finish each part of the work beforehand and store it away until required. Coming back to the master schedule, on Day 2, the car is washed and finished both inside and out. On Day 3, the car is moved to the track where it will stay until turned out. On this day the painters burn the paint off of the car complete. On Day 4, the carpenters start to work on the body and the vestibule of the car. The tinsmith and the truck gang also start their work on this day. It will now be seen that all crafts are working on this car in order to complete it by the end of the 37 shop days. By the twenty-eighth day, all of the crafts have finished their work. Machinists and blacksmiths finish on the twenty-second day. The upholsterers and brass workers, the electricians, steam fitters and cabinet workers finish their work on the twenty-fourth day. The tinsmiths on the twenty-sixth day and the carpenters on the twenty-eighth day. The car is now free for the painters to work on.

Should any hidden defects appear during this time that will necessitate a longer time than allowed by the schedule to complete the work, this situation is generally overcome by increasing the number of men employed on the job, taking them from a car just in the shop or from one on which there is but little to do. This procedure usually prevents the car from going out late.

The car moving through the shop on schedule *M* is now complete in so far as all the crafts are concerned except



REPAIR CAR DELAY SLIP

Pink delay slip which must be filled out by the foreman who is responsible for retarding the progress of a scheduled car

the painters. The car is now in the paint department where on the thirtieth day the painters start to work on the interior and finish on the thirty-fourth day. The trucks and the bottom of the car are also painted on the thirtieth day. On the thirty-first day the painters start the outside of the car and finish it by the thirty-sixth day. On this day all paint work is finished as well as all the repairs to the air brake equipment. On the thirty-seventh or last day in the shop, the car is in the hands of the trimmers who usually complete their work in time for the shifters to pull the car out of the shop, 99 per cent complete. There is always a final inspection and touch-up time is required, which takes place after the car leaves the shop. When complete, the inspector carefully goes over the car and declares the car ready for service on the date assigned. This is a typical case and the movement of all the other cars through the shop is similar.

The use of the individual schedule board

In order to make this schedule system effective, it is essential to have a number of cars on the waiting list for repairs. With 20 or 30 cars waiting to come in the shop, it is much easier to maintain a steady run of output than is possible if only 6 to 10 or less cars are on hand. These crippled cars can be arranged to pass through the shop in such a manner that neither the paint nor coach shop will be overloaded to the detriment of the other. After the cars have been arranged on the waiting list, according to the class of repairs required for them, the inspector goes over each car in as thorough a manner as is consistent with his other duties, making notes of the condition of the car so that when it arrives in the coach shop the inspector assigned to that shop can, with the data gathered by his colleagues, immediately hang a card on the car which carries a summary of the defects for the benefit of the foreman in whose section the car has been placed for repairs. This card is also of first importance to the schedule supervisor who at a glance can grasp the extent of the necessary work to be done, and with that coupled with his own observation and the chart of the cars in the

coach and paint shop, he can immediately assign a date for the completion of the coach shop repairs as well as of the paint and the trimming.

When the schedule has been determined and the dates have been placed on the planning board, a schedule board is then written up and placed on the car where it remains until the car is complete. The information contained on this board is copied on the form shown in one of the illustrations by the schedule supervisor who sends duplicate copies to each of the foremen who is responsible for any of the work done on the car.

The schedule board is about 18 in. by 24 in. At the top is placed the number of the car and immediately below it, the schedule letter and shop days for completion. Below this appears the number of days in the shop and following this is a list of the various operations to be performed on the car with the start and finish time after each item.

This form contains the same information found on the schedule board which hangs on the car under repair—A duplicate is sent to all the foremen interested

The start and finish columns are important, and as each day passes the checker marks off the vital days as they terminate until he comes to the day on which the work of the carpenters should be complete. If the car is delayed a day or more, every day it is late is checked off the schedule and a report is filed in the office of the general foreman for his information. If the information is sufficient and satisfactory, the general foreman accepts the report, but if he feels that it is not acceptable, he asks for a pink slip, or repair card delay slip, from the foreman in charge, which must clearly state the cause or causes of delay. If these causes are such as will warrant the excuse of the foreman then the delay is passed on to the originator of the cause. This delay slip, which is shown in one of the illustrations, is very effective as the foremen bend every effort to avoid a pink slip. As a result of this co-operation on the part of a foreman, a delay chargeable to negligence has never been filed at the North Billerica shops.

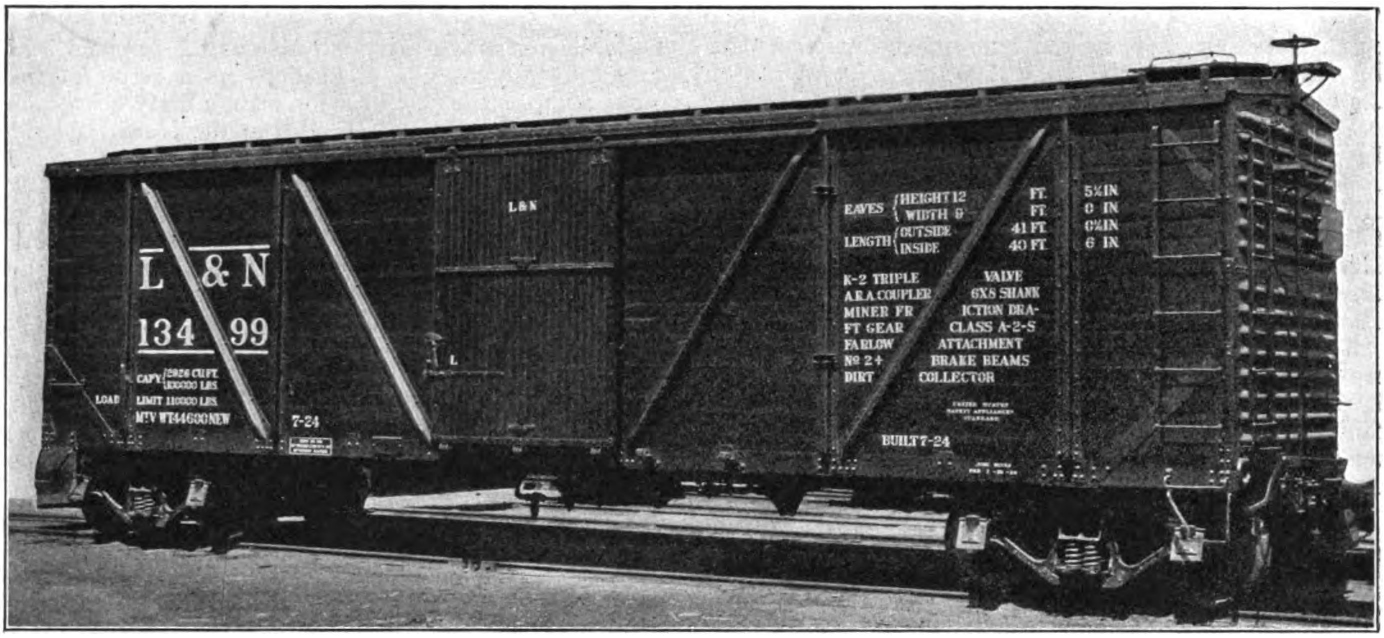
The different crafts working on the car within the carpenter days, do so according to the days which are assigned for their particular work. As each craft completes his work, the foreman O. K.'s the board against his craft's name, so that when the coach shop foreman is ready to send the car over to the paint department, he looks over the schedule board on the car to determine if the tinsmith, truck department, etc., have completed their work as required. With the board completely checked off, the paint shop will have no delay on account of work not being finished in the coach shop. Neither will the painter have any hammering on the body of the car which causes dust to fly through the air and settle on the fresh varnish, which naturally does not add to the appearance of the finished car.

The master schedule is supplemented by a large planning board which carries 31 blocks, to cover days in the longest month. Each block is divided vertically into four columns, one each for the car number, the date in, the schedule designation and the date out. Horizontally, each block is divided into two parts, one for the coach shops and one for the paint shop, and each of these parts contains six horizontal lines to accommodate a record of a maximum of six cars. As each car is given a date out of the coach shop, the car number, its date in, schedule designation and final completion data are entered in red in the coach shop portion of the block representing the schedule day out of the coach shop. The same information, with the exception of the completion date is entered in blue in the paint shop portion of the block representing the final completion date. The purpose of placing the car number in these spaces is so that no more than four or five cars, which carry the same completion date will be scheduled out of either the work or paint shop on the same day, as any more than that number would mean a delay. The daily capacity of the paint shop is around four to five cars. Therefore, in order to avoid confusion, it was found necessary to employ some scheme of separation. The planning board tends to smooth out the output in a steady, even flow of a predetermined number of cars for each day.

Benefits derived from a scheduling system

Schedule boards indicate infallibly where delays periodically or persistently occur and such departments may be built up or strengthened. Under the day work plan, which is used at this shop, the system acts as a stimulant and to some extent, takes the place of interest in the work removed through the abolition of piece-work methods. Friction between departments is almost entirely eliminated. It is not possible to unload on one department causes for delay which belong to another.

This system to some extent establishes tasks or jobs. Every conscientious foreman or workman likes to have certain work to perform in a stated time and to feel confident that this is exactly what is wanted. Each schedule date delivered to the foreman or workman becomes a written order to that man to deliver the work on that date. Unnecessary driving is brought to a minimum. Dates are assigned and if the work is properly done on these dates, no criticism or censure is necessary. The constant reappearance of the daily delay report stimulates foremen and workmen to a better purpose than criticism. Scheduling has enabled us to reduce our man power to the proper ratio to the output.

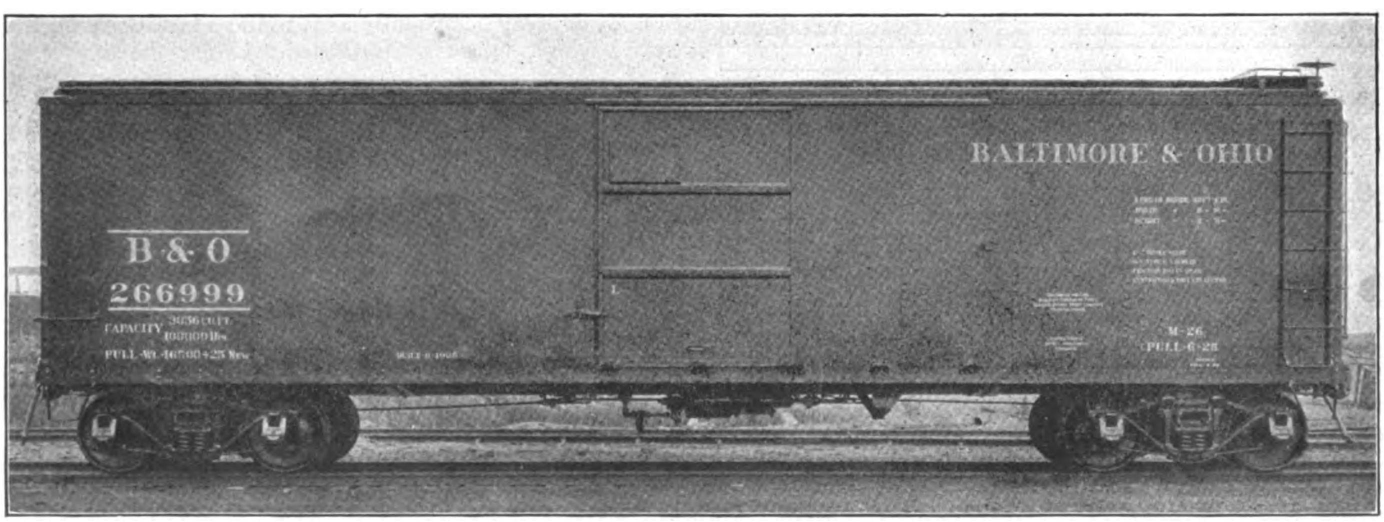


Louisville & Nashville standard 50-ton single-sheathed box car—Builder, Mt. Vernon Car Manufacturing Company

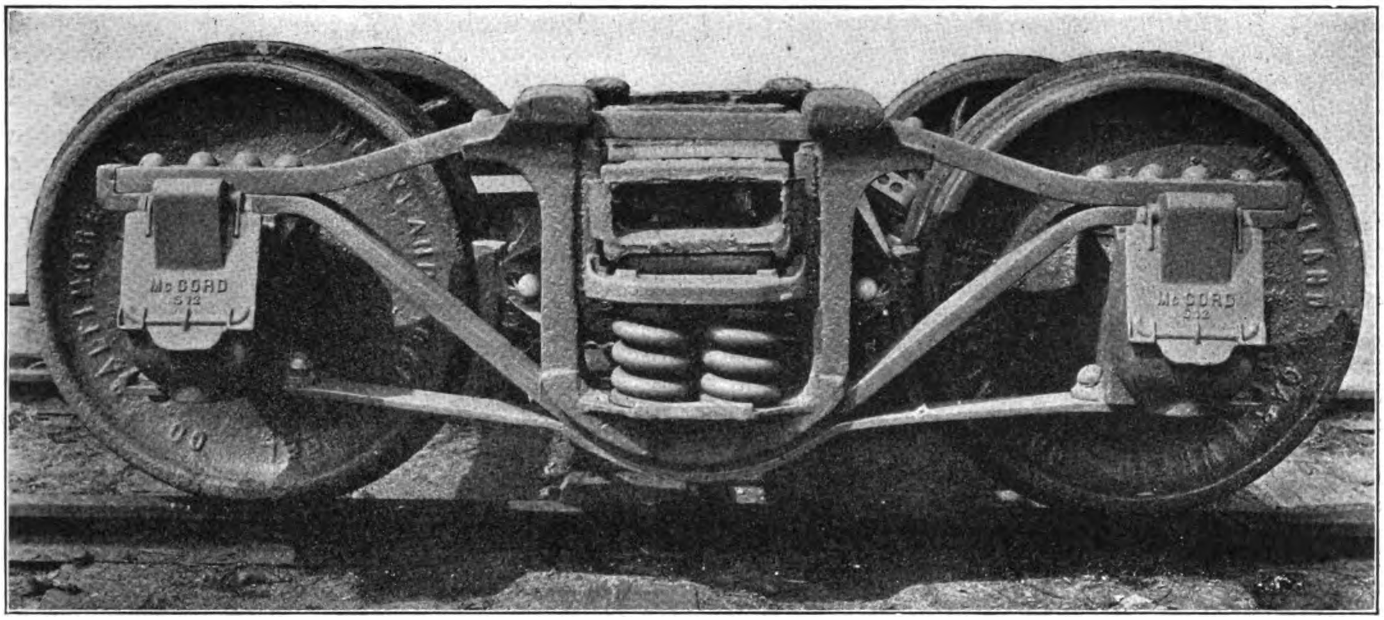
Exhibit of proposed standard box cars at Chicago

Built from designs proposed by Committee on Car Construction—B. & O. shows two all-steel cars with trucks of special design

ONE of the features of the recent meeting of the Mechanical Division of the American Railway Association held at Chicago was the exhibit of the present and proposed standard box cars which was shown on tracks No. 4 and No. 5, slip A, South Water street yard of the Illinois Central. This exhibit constituted a most instructive and valuable supplement to the report of the Committee on Car Construction, an abstract of which was published in the July *Railway Mechanical Engineer*. These cars, which included both the proposed double—and the present standard single-sheathed types, were sent to Chicago by a number of representative railroads. They were interesting, not only because they were built in accordance with the standard designs as worked out by the committee, but also on account of the fact that they embodied many alternatives which can be applied without departure from any essentials of the standard design. In addition, the B. & O.



Baltimore & Ohio 50-ton double-sheathed box car—Builder, Pullman Car & Manufacturing Corporation



The Tatum XLT truck used on one of the Baltimore & Ohio box cars

also exhibited two all steel cars equipped with trucks of special design. The following is a brief description of these cars.

The A. T. & S. F. 40-ton double-sheathed box car

An illustration of the A. T. & S. F. 40-ton double-sheathed box car of the proposed standard design 4C-XM2 was shown on page 426 of the June *Railway Mechanical Engineer*. The equipment thereon includes:

Trucks: A. R. A. side frames on both trucks. The truck at the "A" end of the car has an A. R. A. bolster design with separate center plate and standard friction side bearings The truck at the "B" end of the car has a separate center plate and bolster design modified to accommodate the Barber lateral motion device and Barber roller side bearings. A. R. A. standard springs and spring plank are used on both trucks.

Brake beams: The truck at the "A" end is equipped with a Creco No. 2 beam and standard A. R. A. suspension hanger. The truck at the "B" end has a Creco No. 2 plus brake beam, Santa Fe standard malleable hangers and Santa Fe brake beam safety suspension.

Connections and truck levers: A. R. A. standard is used with both.

Journal box lids: The truck at the "A" end has Asco self-fitting torsion spring lids; the "B" end of the car has Symington B-2-A malleable lids.

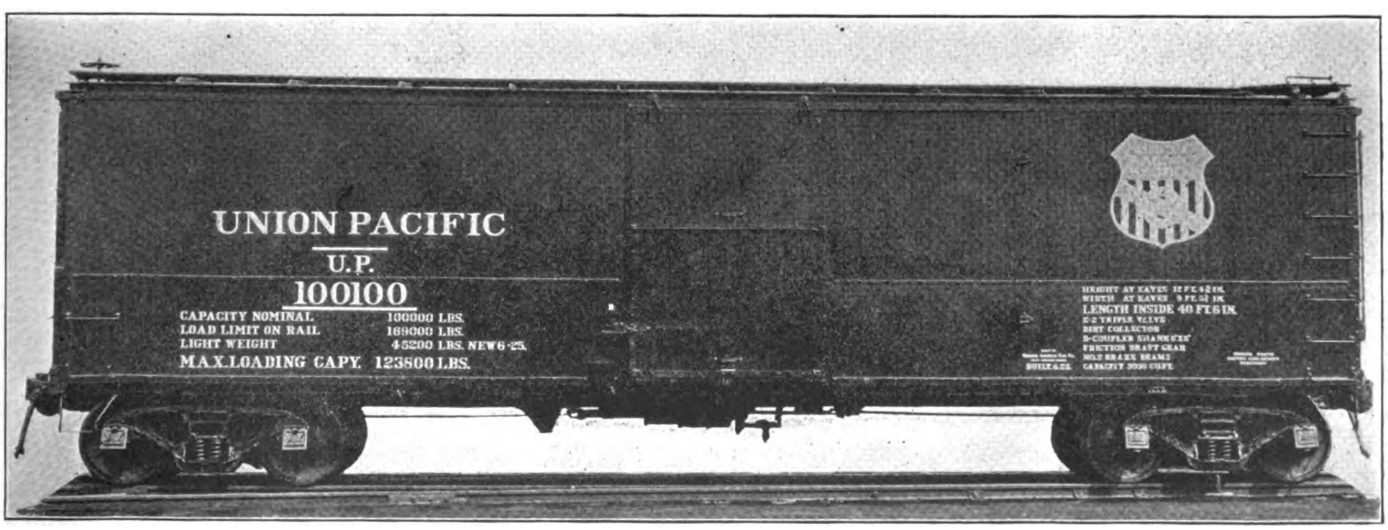
Ends: The "A" end of the car has a built-up standard end with posts; the "B" end has a Murphy corrugated end.

Side doors: Both doors are bottom hung. One door has A. R. A. standard sections of framing. The door posts on one side of the car are pressed as shown on the proposed standard design (see page 433, July *Railway Mechanical Engineer*); the other side of the car has the front door posts pressed, but with the front stop omitted. The front stop is a Camel section, riveted to the post. The rear door post is pressed with the outside flange omitted, and Camel weather strips are riveted to it. The rear frame of the door on this side of the car has a Camel standard pressed angle, while the front framing includes a Z-bar providing the necessary lap in the front stop. The top and bottom framing is made of Z-bar sections, as shown on the standard details.

Roof: Murphy radial all-steel flexible roof.

Yokes: Santa Fe standard cast steel yokes made by the American Steel Foundries.

Draft gear: National friction draft gear, type M/17,



Proposed standard 50-ton box car with wood sheathing and lining—Builder, General American Car Company

at the "A" end of the car, and Miner friction gear, type A-2-X, at the "B" end of the car.

Uncoupling device: Santa Fe standard, Imperial type A at both ends of the car.

Body side bearings: At the "A" end of the car, A. R. A. standard design. Those at the "B" end of the car are modified to accommodate Barber roller side bearings.

Air brake: Westinghouse.

Marking: Santa Fe standard, conforming to A. R. A. specifications.

The Union Pacific 50-ton double-sheathed box car

This car is 46 ft. 6 in. long inside and has a capacity of 3,038 cu. ft. The light weight is 45,200 lb. which leaves a maximum loading capacity of 123,800 lb.

The equipment on this car, which is of the 4D-XM2 class (see page 428, July *Railway Mechanical Engineer*), includes:

Trucks: The "A" end has Huntoon brake beams, Schaefer brake hangers, levers and connections; Wood's roller side bearing, and Allegheny Steel Company's journal box lids. The "B" end has Creco beams and Railway Steel Spring Company's journal box lids.

Ends: The "A" end of the car has a corrugated end; the "B" end of the car is of the standard built-up type.

Uncoupling device: Carmer.

Side doors: One side has an A. R. A. standard top-hung door and fixtures. The other side has a modified Camel top-hung door and fixtures.

Roof: Murphy solid steel riveted type.

Yokes: Buckeye steel yokes at both ends.

Angle cock holders: Western Railway Equipment Company at the "A" end, and A. R. A. at the "B" end.

Draft gear: Murray on one end and Cardwell on the other end.

Air brake: New York.

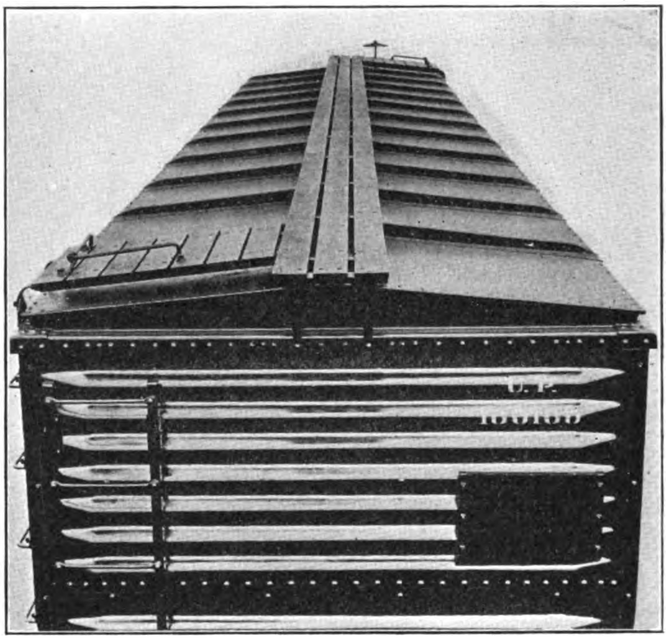
Nuts: Grip and boss nuts.

Marking: Union Pacific standard.

Notes on the 40 to 50-ton double-sheathed cars

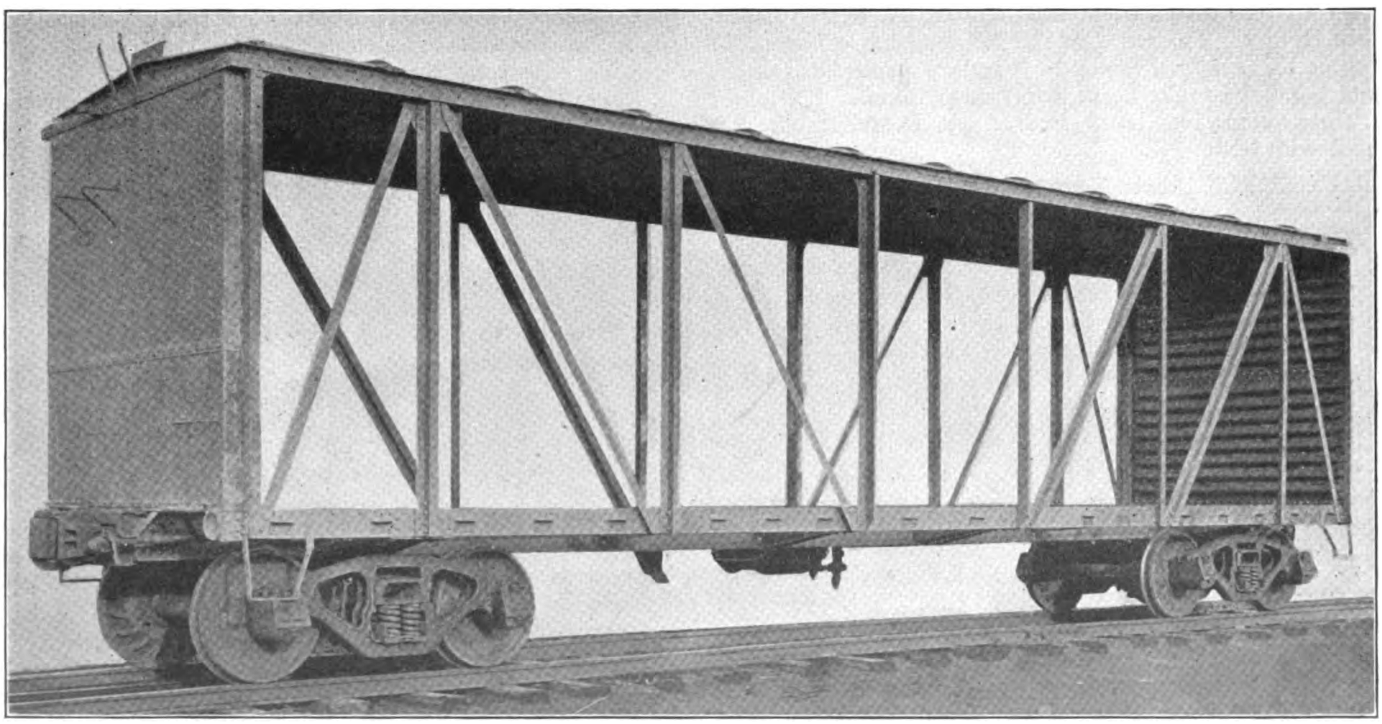
In general construction the 40-ton and the 50-ton double-sheathed box cars are the same, although various parts are naturally of lighter construction for the 40-ton car. Some of the differences are enumerated herewith.

The underframes are of the same standard section as that previously adopted for single-sheathed cars, the differences in the frames being so slight that if adopted for the double-sheathed car the same design could be incorporated in the single-sheathed car. The crossbearers have been moved to coincide with the location of the door



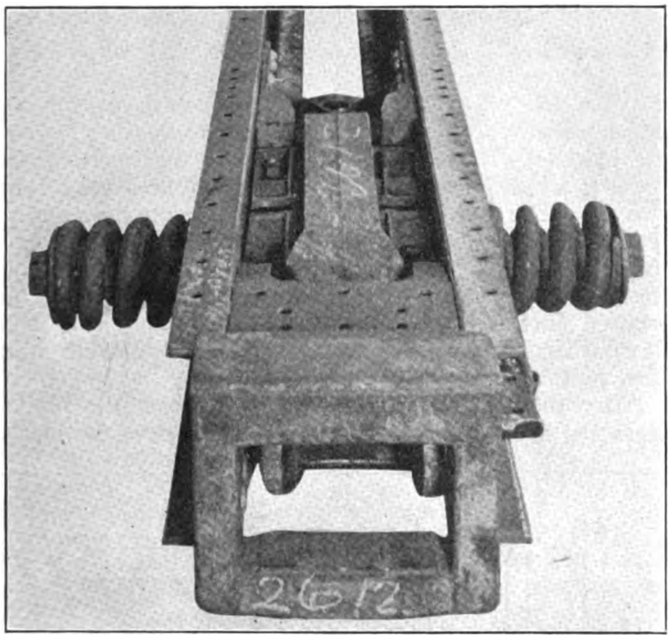
Murphy solid steel roof and the corrugated steel end of the Union Pacific car

posts, a change that could readily be adapted for single-sheathed cars. The body bolster top cover plates are ½-in. thick for 50-ton cars and ⅜-in. thick on 40-ton cars. The same difference occurs in the crossbearer top cover plates. These dimensions can apply also to single-sheathed cars. The side sills are punched the same for



Body framing of the Union Pacific car, mounted on temporary trucks—Built-up steel end at the left

both top and bottom-hung doors. The Z-bar side plates are 1/4-in. thick for 40-ton cars and 5/16-in. thick for 50-ton cars. The transom posts are 3/8-in. thick for 40-ton cars and 1/2-in. thick for 50-ton cars. The punching for posts, braces, sills and plates are identical for cars of either capacity. The end sill angle has been shifted 1 7/16-in. but the same punchings of the underframe have been retained, the punching of the sill being changed to



Combined draft gear lug and end stop casting

suit. The end plates are the same shape but they have been offset in order to accommodate vertical posts or built-up ends. The holes in the end sill angles have been spaced so as to take a standard uncoupling device.

A particularly interesting feature of the design is the combination dead block and front draft lug. This combination is shown in one of the illustrations.

Louisville & Nashville car

The sample car exhibited by the Louisville & Nashville is of the standard single-sheathed design, in the construction of which a number of alternates have been incorporated. It is of 50-ton nominal capacity and weighs 44,600 lb. light. It has corrugated steel ends and XLA outside flexible metal roof. The draft gear is Miner friction, class A-2-S with Farlow attachments; the coupler release attachment is the Carmer. The trucks have cast steel side frames with journal boxes cast integral. The truck bolsters are fitted with roller side bearings.

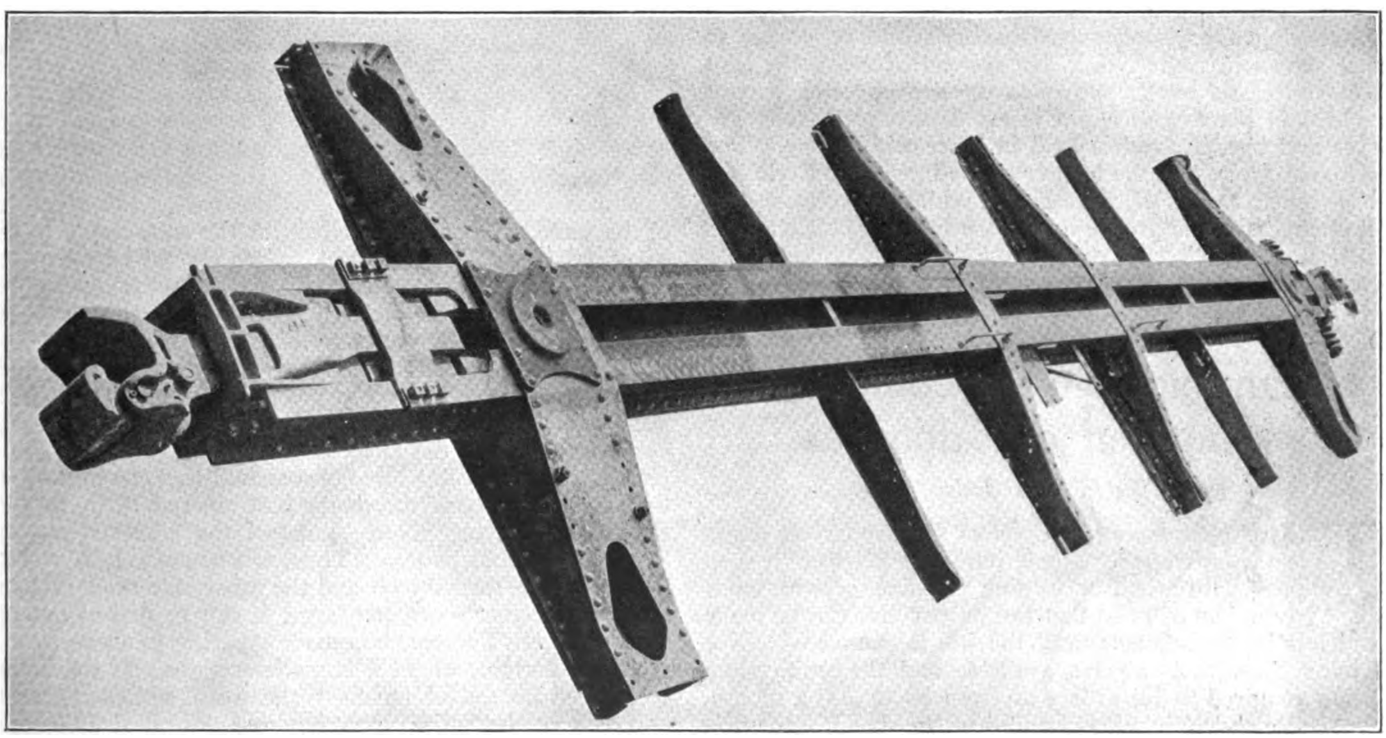
The B. & O. double-sheathed cars

Two 50-ton double-sheathed cars with two new types of trucks were exhibited by the Baltimore & Ohio. These are 40 ft. 6 in. long, 8 ft. 9 1/8-in. wide and 8 ft. 7 3/8 in. high—all inside measurements. The capacity is 3,056 cu. ft. The light weight is 46,900 lb. which leaves a maximum loading capacity of 122,100 lb.

One of these cars was equipped with the Tatum patented arch bar flexible truck which is built without bolts, nuts, washers or keys, except for the brake pins and the lower connecting rod, and the brake pin used in the live lever rod connected to the bottom brake rod. The column post is locked to the top arch bar by wedges and rivets. The bottom arch bar and the tie bar are free from any sharp bends. The side frames are flexibly connected by a 6-in. pivoted channel bar. This truck design includes the Tatum-Zell waste and oil retainer, a brake beam suspension without brake hangers and fulcrum bar safety straps.

The other car was equipped with the Washburn patented arch bar truck side frame, which was described in the *Railway Mechanical Engineer,* May, 1924. There is quite a difference between the weight of the Washburn truck and the standard M. C. B. truck. The M. C. B. arch bar truck with 1 1/4-in. by 6-in. arch bars weighs 8,640 lb. with the lateral motion device. The XLT truck weighs, without the lateral motion device, 8,145 lb.

In discussing the 1925 report of the Committee on Car Construction one of the committee members, J. J. Tatum,

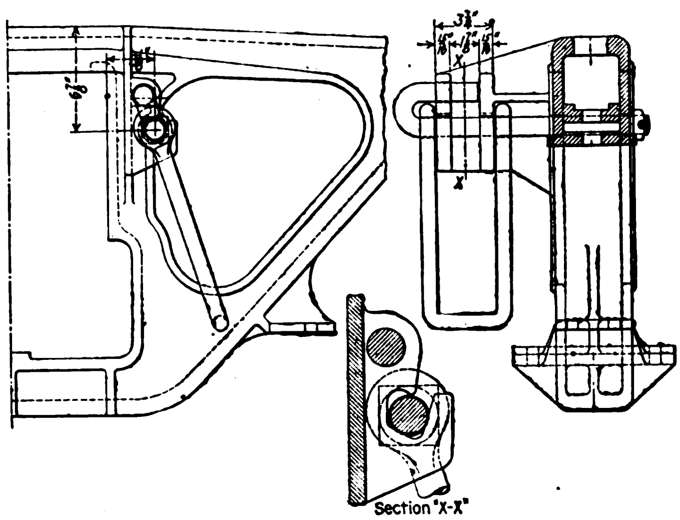


Inverted underframe of the proposed standard double-sheathed box cars

general superintendent car department, Baltimore & Ohio, stated that the committee was not prepared to give the comparative strength of the two trucks under the two different cars, but the M. C. B. arch truck under a static load of 125,000 lb. deflected 1.50 in. and had a permanent set of 1.23 in. The XLT truck under the same load deflected 0.19 in. with a permanent set of 0.10 in.

Proposed brake hanger bracket

The Baltimore & Ohio is also investigating the possibilities of a brake hanger bracket for cast steel truck side frames. Five proposed styles have been developed, of which Style No. 2 is shown in the drawing. The bracket design is the same for all five proposed styles. The method of applying the hanger, however, is different. The hanger shown in the drawing is the proposed A. R. A.



Proposed Style No. 2 of brake hanger bracket for cast steel side frames

standard brake beam hanger, Classes 2C, 2D and 2E. Style No. 1 is made to the same dimensions as the proposed standard hanger, but is forged in a solid loop, the top portion of which is flattened so that the hanger can be inserted into the hook of the bracket. The proposed standard hanger is also used in Style No. 3, similar to that shown in Style No. 2, but instead of using the bent bolt and castle nut as shown in the drawing, the hanger is held in place with a pin inserted through the hanger eyes and bracket, and is held in place with a key. The method of applying the hanger to the bracket in Style No. 4 is similar to that of Style No. 2, with the exception that the hanger is made to be inserted inside the bracket jaws instead of outside as shown in the drawing. Style No. 5 employs the same type of hanger as Style No. 4 but is secured by a pin and key as in Style No. 3.

Manufacturing eyebolts for hopper car doors

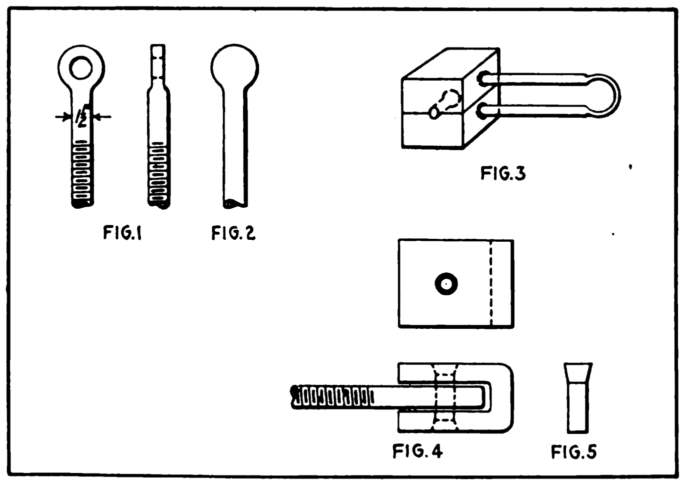
By F. E. Deissler

THE manufacturing of eyebolts for hopper car doors is a comparatively simple job if the blacksmith shop is equipped with a bolt or forging machine, or with sufficient power hammers so that the proper dies can be made and left in the hammer until the job is completed. Not having these tools always available and the smith shop being required to fill orders of from 50 to 200 a month, the device shown in Figs. 3 and 4 of the sketch was made so that the steam hammer could be used for other work when necessary.

The kind of eyebolt made is shown in Fig. 1. The material used is 2½-in. round stock which is cut off at the shears to the required length, heated, balled at one end and flattened. The other end is then drawn out to 1½ in. diameter. Sufficient heat remains to punch the hole while the piece is still hot and the job is completed except for the threading.

The tools used for this work are the spring swedge, shown in Fig. 3 and the die and punch shown in Figs. 4 and 5. These tools are made by forging a master ball as shown in Fig. 2. The two blocks of steel for the spring swedge are then forged to the required size and reheated. The master ball is placed between the two blocks which are driven together under a steam hammer. After the blocks are cooled, holes are drilled the same size as the bar used for the handle as shown in Fig. 3, and shrunk. The job is completed by inserting the ends of the spring handle in the holes and electric welding around the handle to prevent it from coming out or turning. If the electric welder is not available, the handle can be secured just as satisfactorily by drilling a ¼-in. hole down through the block and handle and driving in a steel plug.

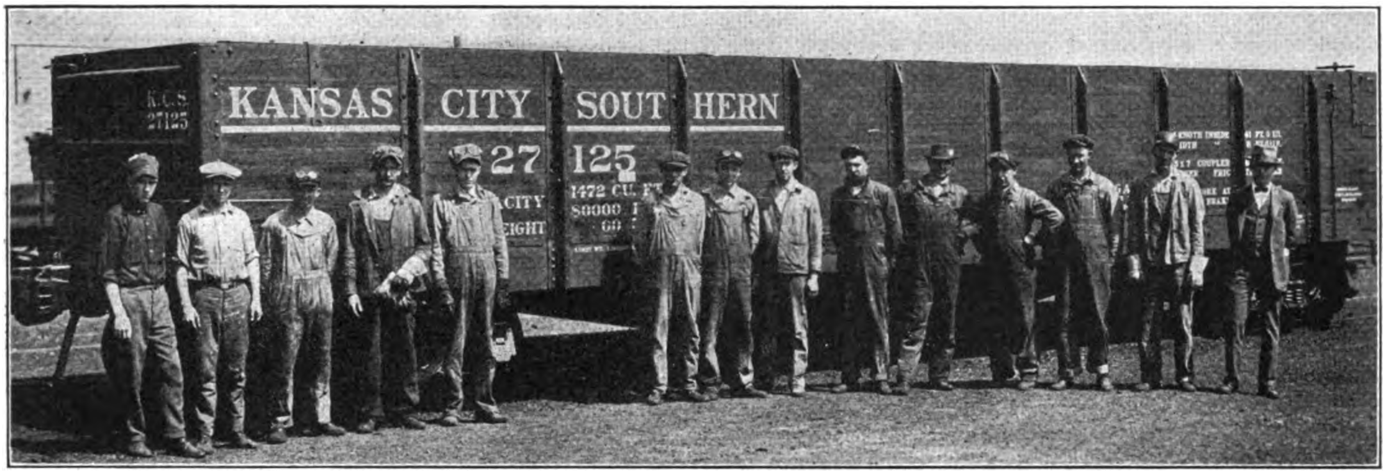
After the handle has been applied, reheat the blocks, place the master ball in the swedge and close the blocks



Quantity production of eyebolts can be obtained with this device on a power hammer—No permanent dies or special equipment are required

down until they come together, using a little water on the master ball to help clean out the scale and make a smoother tool. The swedge for the bolt shank is made in the same manner as described for the ball, only a piece of round iron is used instead. Care should be taken to make the grooves wide enough and at the right depth so that the work can be turned freely and the swedges will not pinch at the edges.

The die and punch are made as shown in Figs. 4 and 5. The die is made from a piece of 1½-in. tire or tool steel bent to the shape shown, allowing about ¼ in. clearance between the sides of the opening and the material to be punched. The holes should be 1/16 in. larger than the diameter of the punch and tapered ⅛ in. larger at the top, leaving about ½ in. of the hole straight at both the top and bottom. Thus, when one side is worn, the die can be turned over and the other side used. When the hole becomes worn too large, it can be drilled out to a larger size. The punch is made tapering to about ½ in. from the bottom, where it is made straight. If the holes are drilled instead of punched, the work will cost nearly as much as the entire operation just described. On the other hand, if the eyebolts are finished cold, the work will require extra handling, which adds to the cost.

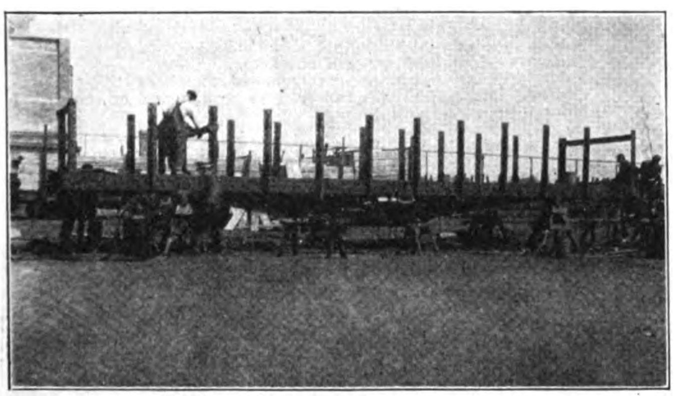


The completed car and apprentices who repaired it—C. Y. Thomas, apprentice supervisor, at extreme right

Apprentices repair gondola unaided

Kansas City Southern car shop apprentices give practical demonstration of their knowledge

WITH no intention of breaking records, but simply to show the results of apprentice training and to increase the incentive and interest of the boys in their work, it was recently decided to have a group of apprentices at the Pittsburgh, Kans., shops of the Kansas City Southern completely rebuild a freight car. As a result, 13 of these boys were selected, and they performed without assistance all the operations involved in giving Class 1 repairs to a composite gondola in four days, or slightly over five days if the time required for painting is counted. A 27,000 series, K. C. S. coal car was chosen for the test, this type of car having a steel underframe and being of 40 tons capacity, 42 ft. 7½ in. long and 8 ft. 10¾ in. wide, equipped with Andrews trucks. These cars were built in 1913 and are now being given heavy repairs for the first time.



Lining up side stakes after riveting—Body bolsters riveted in —Straightening end sill, B end

The car selected, No. 27,125, was set at the Pittsburgh steel car shop May 11, being left outside the shop to facilitate photographing. It was stripped of sides, end boards and nailers, the stripping being done as usual by laborers on the stripping track. Laborers also sand blasted the underframe.

The apprentices working the car were placed under the direct supervision of an apprentice who acted as lead man. No assistance of any kind was given the apprentices by the car repairers, car foremen or lead man. All necessary instructions, few in number, were given by the supervisor of apprentices, C. Y. Thomas, and the superintendent of machinery, M. A. Hall, who kept in close contact with the progress of the work because of his keen personal interest in the apprentices and all that they do.

The apprentices selected and assigned to the work on the car were as follows:

Lead man	George Dixon
Gun men	Ben Throne and Oliver Foltz
Buckers	Glen Watson and Gerald Burris
Pickups	John Baker and Hughie Carey
Heater	Floyd Clanton
Mill work	Wilfred Atkinson and Walter Hanes
Air work	Wilfred Atkinson and Milford Stuckey
Painters	Kenneth Lindsay and Elmer Wolfe

The average length of apprenticeship of these boys was approximately 14 months. While the purpose of the test was to show what the apprentices could actually do and it was not intended to be a time or small cost performance, the repairs on the car were made as rapidly as consistent with good workmanship. The total time required, as well as the time when each operation was completed, is shown in the Log of Repairs. The total cost of the job for labor and material was $880.74.

The trucks were in poor condition and it was found necessary to dismantle and completely rebuild them, using the following new parts:

2 new cast steel truck bolsters	4 new Andrews side frames
2 new pairs of wheels	4 new spring caps
1 new box lid	4 new spring rests
16 new box bolts	4 new journal brasses

After assembling the truck next the shop building, it was inverted to facilitate riveting the spring planks and bottom tie bars, while the other truck was jacked up alternately on its sides to be riveted. As soon as the riveting was completed, the boxes were packed and the center plates greased, making the trucks ready for application.

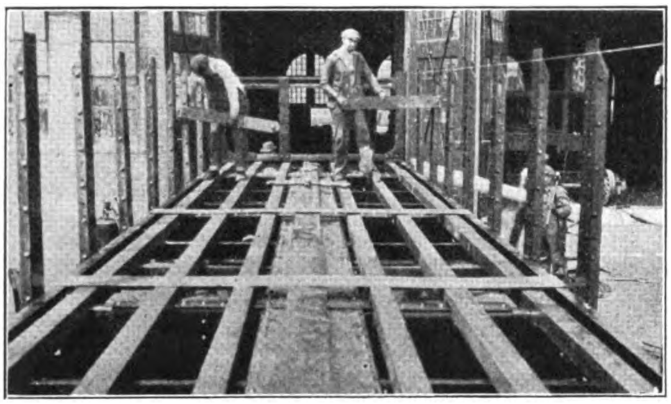
The cars of this series are equipped with Miner A-24-S friction draft gears and but few of the gears have received attention since application. After removing the

couplers and draft gear, it was decided to replace the old Simplex couplers with A. R. A. type "D" couplers and it was found that the gear on one end of the car had been recently worked and did not need attention. The other end, however, needed a new barrel, and the assembling of a new barrel and gear, which was planned to be done by the apprentices, was not carried out because no new barrels were on hand. A gear already assembled was used.

Westinghouse type "K" triple valves and centrifugal dust collectors are standard on these cars but this car came in without a dust collector and with a New York triple valve. It was necessary to make the proper repairs on these parts. The brake pipe was in fair condition and only a few fittings were necessary. Two repaired air hose and two repaired angle cocks were applied and the car was tested and found satisfactory except for the piston travel which was adjusted to the proper length.

A programmed A. F. E. on these cars calls for the application of new needle beams and side stakes. Inspection showed that the two left hand needle beams should be renewed; both end sills required straightening, and one new end sill cover plate was necessary.

Using the Red Devil rivet cutters, the old stakes, needle beams and bolsters were cut out. In some cases it was necessary for one of the apprentices to cut out rivets with an acetylene torch. The four sections of the new body bolsters and the two needle beams were first placed and fitted up for riveting. Then the sixteen intermediate side stakes and four needle beam side stakes were placed and fitted up for riveting. After all these were riveted, the end sills were straightened and one new end sill cover plate fitted up and riveted in place.



Nailers in and bolted down—Tie straps in place

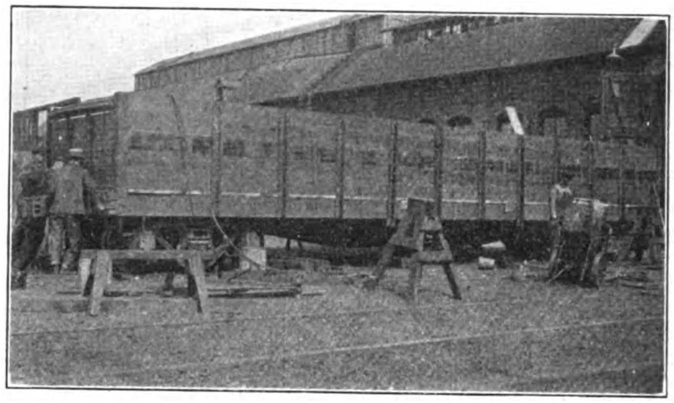
As soon as the steel work was completed, the underframe was spray painted, the nailers bolted down and new decking nailed down. One end of the car was then lowered on its truck. The side boards were bolted in place, being pulled down by a hook and chain running over the top angle iron. While the side boards were being applied, the end boards were fitted in place. The bolt holes in the side and end boards were drilled with an air motor and the nuts were run up by hand. The other truck was then put in place, its application having been delayed due to the necessity of re-driving some tie bar rivets.

As soon as the side and end boards were fixed in place the miscellaneous items such as grab irons, brake steps, coupler pin lifter, etc., were applied and the car was ready for painting. The side and end boards had received one coat of paint prior to application and the car was given another coat of paint the afternoon the mechanical work was completed. A third coat of paint was sprayed on the next day and it was allowed to dry a full day before the stenciling was applied.

Log of repairs

1—Time of start	8:15 a.m. May 11
2—Air brake equipment and piping removed	8:30 a.m. May 11
3—Side stakes cut off	8:45 a.m. May 11
4—Trucks out—car on horses	9:00 a.m. May 11
5—Draft gear dropped	9:30 a.m. May 11
6—Bolsters and needle beams cut out	11:00 a.m. May 11
7—Draft gear applied	2:30 p.m. May 11
8—Bolsters and needle beams applied	3:00 p.m. May 12
9—New stakes applied	3:30 p.m. May 12
10—Trucks ready for application	3:30 p.m. May 12
11—Trucks under car	8.30 a.m. May 13
12—Nailers bolted in	2.30 p.m. May 13
13—Decking down	4:00 p.m. May 13
14—Air brake equipment applied	10:30 a.m. May 14
15—Air brakes tested O. K.	1:15 p.m. May 14
16—Side boards in place	2:30 p.m. May 14
17—End boards in place	3:00 p.m. May 14
18—Safety appliances on	3:00 p.m. May 14
19—First coat of paint on	4:00 p.m. May 14
20—Second coat of paint on	9:15 a.m. May 15
21—Stencilling completed and car out	10:30 a.m. May 16

Under the standard schedule for determining the classification of freight car repairs, car 27,125 received Class 1 repairs, which required the following operations:



Side and end boards in place ready for drilling and bolting

A—New roof.
B—New siding complete.
C—New deck complete.
D—Two or more longitudinal sills.
E—Posts and braces renewed complete.
F—Side plank on gondola cars renewed complete.
G—Steel longitudinal sills two or more straightened or renewed.
H—100 or more rivets renewed.
I—Repaint and stencil complete.

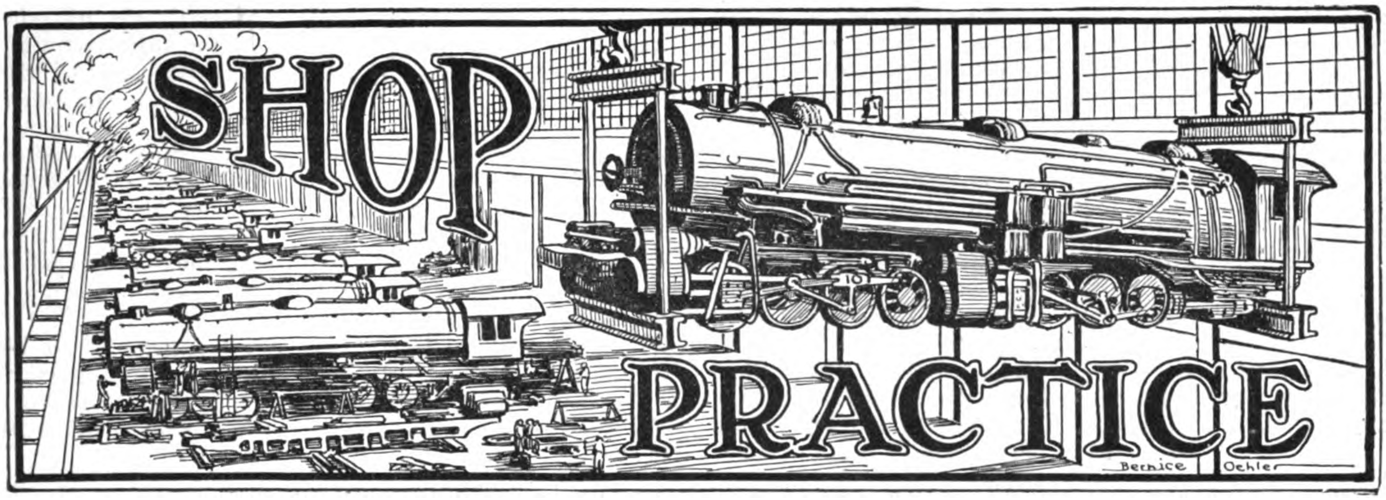
Note—Necessary air brake and truck repairs must be made to secure this classification.

Form 505 report of repairs incorporated in this report shows in detail the new parts and repair work on the car and the cost, a detail of which is given below:

Stencilling the car

	Labor	Material	Total
General repairs	$175.76	$668.70	$844.46
Replacing in kind	....	12.76	12.76
Additions and betterments	9.40	14.12	23.52
	$185.16	$695.58	$880.74

The car after being completed was inspected and approved for service.



Distribution of overhead charges in locomotive shops

Cost per hour to operate a machine suggested as accurate basis on which to distribute total overhead costs

By W. A. Jones
London, England

IN considering the question of overhead charges as applied to locomotive shops, three of the outstanding features that have never failed to appeal to the writer have been: first, the vague notions held in many cases as to what such charges consist of; second, the high proportion that such charges form of the total cost of a locomotive; and third, the varied and diverse methods by which they are included in the accounts.

Equally with his fellow engineers in other lines of business, the locomotive engineer cannot fail to have at least some interest in the cost of his product and, at the risk of being considered too elementary, it may not be unfruitful if I refer somewhat lightly to these three points. Before doing so, however, it will not be inopportune at this stage to record an opinion freely expressed to the effect that accuracy in costs is by no means so important in the locomotive industry as in those branches of industry where competition is more keen. With this view it is difficult to agree, since the necessity for reducing expenditure has never been more strongly urged on railway executives than it is at the present time. This has led to a number of cases of work being given to outside repair shops that have always been carried out in the locomotive shops. It needs no emphasis to show that the locomotive shops that are able to produce and substantiate the costs of production will be in a much stronger position to meet competition of this nature.

What overhead charges consist of

Reverting back then to the first of these points. Overhead charges may broadly be considered as every item of expense pertaining to the running of a works other than the actual material used, and the direct wages expended, on productive orders. As an example, an operator turning up a pair of drivers will have a definite price paid him for his labor and which will, as a matter of course, be debited as a direct charge against the cost of the wheels. The upkeep of the lathe, apart from the original capital outlay involved in its provision, use of power, cost of supervision, etc., all have to be reckoned with and fall under the heading of overhead charges.

Of the second point, it may be a matter of surprise to learn that in a self-contained locomotive shop making its own castings, forgings, etc., the overhead charges not infrequently, amount to no less than 40 per cent of the gross cost of a locomotive. At the same time we must consider the heavy and expensive nature of the plant necessary for the production of locomotives. In a recent case of an order going through a large locomotive works for a number of 4-6-0 superheater passenger locomotives, the total cost of which amounted to approximately $25,000 each, the overhead charges worked out at $9,750 each. When it is realized that this sum is higher by about 50 per cent than the cost of raw material, the importance of not only a true understanding, but the necessity for a close watch on such expenses will be readily appreciated.

Reference to the third point; viz., the allocation of such charges, may reasonably be left to a later stage and, without further introduction, let us consider the main items of expense that are normally classified under this heading. These are:

1—Cost of power.
2—Rent and rates of buildings, together with the lighting and necessary heating.
3—Maintenance of the plant.
4—Maintenance of buildings.
5—Depreciation.
6—Clerical and supervisory staff.
7—Laborers.
8—Transport charges i. e., cranes, yard locomotives, etc.

Reviewing for a moment our previous example of an

operator turning a pair of drivers, he will doubtless require among other things, the use of a crane to put them in and out of his machine, the assistance of laborers, while the wheels will most probably be brought into the shop on trucks drawn by a works locomotive. All these services have to be paid for and require debiting in as equitable a manner as possible. In many establishments, it is the custom to total these expenses and charge them to the costs as a percentage of the direct wages. For a works producing one type of product this method is doubtless satisfactory, but where the product itself is varied and the tools used in getting out the product are different for each of the various units produced, as for instance a flanging press in the boiler shop and an engine lathe in the machine shop, this method of distributing overhead is both incorrect and misleading in its final figures. There is no more justification for considering that a dollar's worth of labor actually applied to a locomotive part should always take the same percentage of expense than there is for the assumption that a tire mill and a drilling machine cost the same either in initial expenditure or operating cost. With the same reasoning, one would say that the overhead cost of maintaining repair benches and assembly floors is the same as for maintaining and operating machines, obviously an incorrect hypothesis.

Allied to the above method is the one whereby the expenses are charged according to the numbers of hours spent on the respective jobs. This method is subject to the same criticism in that the assumption is made that the overhead expenses have a fixed ratio to the hours spent on a job. Granted that a certain portion of such expenses as supervision, insurance, time clerks, etc., can reasonably be considered as proportionate to the time spent, these in themselves form only a minor portion of the gross charges. Moreover, an employer does not necessarily reduce his clerical and supervisory staff every time business falls off to such a point that he has to lay off some of his men, and the hourly cost would, therefore, vary sufficiently to nullify any advantage claimed. Particularly is this so when this advantage consists chiefly in compensating for the difference in wage rates by substituting hours worked for wages paid.

It will be observed that each of these methods, instead of dealing with the overhead charges as a separate entry, link them up with either the direct wages or the time spent, and any fluctuation in these will at once alter the amount of overhead debited to any particular job. This viewpoint is emphasized by the following illustration. In one locomotive works it was the practice to vary the prices paid for any given job according to the standard rate of the operator engaged on it. Now, since the overhead expenses were debited as a percentage of the direct wages it will be readily understood that there was at times quite an appreciable difference in the total cost of the same article. Exactly the same type of machine was used in each case, and the time the machine was in operation was approximately the same, yet the net result of the methods was that the amount included for overhead was considerably less in the case of the job being carried out by the lower rated man. Further, when quoting for or obtaining the cost of any piece of work, the first step is usually to find the cost of the raw material used, then the direct wages spent on it, and it is surely reasonable to ask that as near as possible we should demand the same accuracy in allocating the overhead charges.

Machine hour rate used as a basis of allocating overhead charges

It was with a view to obviating the above mentioned and similar incorrect assumptions that what is known as the hourly rate method has been developed. The machine hour rate consists of distributing all the manufacturing expenses of a works by a charge to each job of the actual cost of operating the various machines and other facilities used on that particular job. This cost is not an average for the whole plant, but is as nearly as possible the actual cost of maintaining and operating each of the machines, groups of machines, or benches found in the plant.

Referring now to the main headings of expense previously enumerated, the methods of allocating them are as follows:

Cost of power—The horsepower absorbed by each machine was obtained, and the cost allocated in proportion to the total horsepower generated and the cost of production. Under this heading was also included the cost and maintenance of shafting, belting, etc.

Rents, rates, lighting, heating, insurances—The total of these expenses are divided by the number of machines and an equal amount distributed against each. In this way a charge per machine is obtained which is practically the same as the owner of a building would offer if he rented it and supplied the light and heat. It has been advocated that this charge should be debited in proportion to the floor area occupied by each machine but, in practice, the individual amount is so small as certainly not to warrant the extra clerical labor involved.

Maintenance of the plant—Standard order numbers are allocated under which all charges for repairs, etc., are collected and debited to each machine or group of machines according to the actual expense involved.

Maintenance of buildings—These expenses are debited in the same ratio as in No. 2. Included in this heading is also an allowance for depreciation, a factor by no means to be lost sight of.

Depreciation of the plant—For this purpose, the lives of the various machines are estimated, together with their value, usually scrap, at the end of this period. The purchase price of the machine, less the residual value, is then divided by the years of estimated life and an equal amount written off annually.

Clerical and supervisory staff—The total of these expenses obtained are divided equally among the number of machines. An exception is made in the case where a small group of machines require the supervision of a foreman, such as automatics, etc., and the charges are then increased accordingly.

Laborers—Each shop is considered as a self contained unit for the purpose of allocating this charge and the gross expense of each is divided equally among the various machines in each shop. The reason for this is that in such shops as the heavy machine shop, boiler shop, etc., the proportion of laborers is much higher than in those shops where the lighter work is carried out.

Transportation charges—A similar problem presents itself here as in the case of No. 6. The cost of the upkeep of cranes and lifting tackle for each shop is readily ascertained and allocated, but the remainder of the works transportation charge is debited according to the size of the shop and the type of work carried out in each.

It may at first sight appear that the foregoing methods involve a vast amount of clerical work and if an individual rate was made for each item of the plant, this undoubtedly would be the case. To obviate this, machines of approximately the same size, similar in consumption of power, etc., were grouped together for accountancy purposes and a rate used for the whole group. By this means the number of rates was kept within reasonable limits and in actual practice, very few more rates were used

than was the case when a percentage on wages figure was used for each individual shop.

An example of how the hourly machine rate is determined

An important point in connection with the allocation of expenses is that they should be based on a sufficiently long period to ensure correct results. In the particular works under review, these were tabulated every six months, and while means were provided for checking the gross amounts debited against the various jobs with the total overhead charge, very little adjustment and alteration of the rates was found necessary. Naturally, the success or otherwise of these methods depend on the amount of attention given to the division of expenses at the commencement, as unless the first rates are approximately correct, the results obtained will be so misleading as to be in effect their own condemnation. The whole process of fixing a rate will be the better understood by an actual example and for this purpose the case of a heavy steam hammer worked in conjunction with an oil furnace has been selected. This is doubtless a more complicated process than the fixing of a rate for a lathe or a fitter's bench but it will at least, serve to illustrate how a plant of this nature is dealt with. The items in question, including expenses of installation, cost \$6,000 and \$800 respectively, were given an estimated life of 40 years for the hammer and 20 years for the furnace and engaged the services of four men. For depreciation purposes, the residual value of the hammer was placed at \$400 and the furnace as nil. The various expenses were then debited as follows:

Expense	Method of debiting	Amount
Power	Proportionate to the volume of steam used; i. e., dia. × stroke of piston.	\$915.00
Oil	Gross cost divided by number of furnaces	515.00
Rent, rates, light, etc......	$\frac{\text{Total for works}}{\text{Number of units}} = \frac{\$112,000}{1,245} =$	90.00
Maintenance of plant, including provision of dies, etc..	Actual cost	945.00
Maintenance of buildings...	$\frac{\text{Total for works}}{\text{Number of units}} = \frac{\$12,700}{1,245} =$	10.00
Depreciation	Hammer $\frac{\$5,600}{40 \times 2} = \$70$; Furnace $\frac{\$800}{20 \times 2} = 20$	90.00
Clerical and supervisory staff.	$\frac{\text{Total for works}}{\text{Number of units}} = \frac{\$99,626}{1,245} =$	80.00
Laborers	$\frac{\text{Total for shop}}{\text{Number of units in shop}} = \frac{\$2,700}{30} =$	90.00
Transportation charges	$\frac{\text{Total for works}}{\text{Number of units}} = \frac{\$11,245}{1,245} =$	9.00
	Total expense	\$2,744.00
	Total hours worked during period	1,201
	Hourly rate	\$2.25

The term units is the total number of items for which the rates were required. Although the number of separate rates did not exceed 20, the hammer dealt with above forming one of a group, for purposes of illustration the data given herewith is on the basis of an individual rate being required.

From the table it will be seen that the gross indirect cost for operating this hammer and furnace amounts to \$2.25 per hour and thus for every job for which this equipment is used, according to the time spent, this addition to the direct wages must be made. The average engineer will scarcely need reminding that this is one of the most expensive portions of the plant to maintain. At the other end of the scale, however, we find that for fitters engaged on detail work at the bench, an addition of 25 cents per hour was quite sufficient to cover the whole of the indirect charges applicable to such labor. In actual practice, experience has shown that the machine hour rate method gave a much closer knowledge and control over overhead charges and enabled us to place a good deal more reliance on the cost figures that were submitted than before. I do not think it an exaggeration to say that so far as accuracy is concerned, everything favors the methods outlined here.

So far as competitive business is concerned, one does not need to think too deeply before realizing that other factors than the actual cost have to be considered when submitting quotations, but at least, it will be admitted that a true knowledge of the costs of production are undoubtedly the safest basis to work on.

In conclusion let me say that all other methods of absorbing manufacturing expenses depend in some way or other on averages, and yet there is no more reason for averaging such expenses than there would be for averaging either the material or the labor costs.

Tool for reaming crown bolt holes

By E. G. Williams

An improved type of reamer for reaming out crown bolt holes in a boiler before tapping, is shown in Fig. 1 of the sketch. The shank of the reamer has a groove which coincides with a hole drilled in the side of the sleeve. It is a difficult matter for the boilermaker to know where to set the sleeve on the shank of the reamer in order not to make the hole too large to be threaded for the next size of crown bolt. The location of the holes drilled in the side of the sleeve is such as

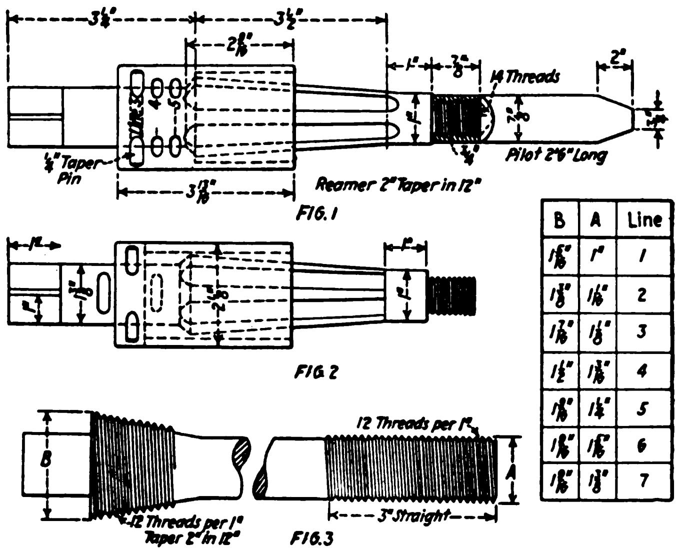


Fig. 1—A crown bolt reamer with an adjustable sleeve; Fig. 2—The old method of adjusting the reamer rather than the sleeve

to provide an accurate setting of the sleeve on the shank of the reamer. These holes are numbered to correspond with a line number of a table shown on a reference print, such as shown at the lower left hand corner of the sketch. The letters *A* and *B* of the table refer to dimensions shown in Fig. 3.

The advantage of having the line numbers on the sleeve instead of on the reamer, as shown in Fig. 2, is that the boilermaker is not so apt to make a mistake in locating the proper groove. In Fig. 1 the shank of the reamer has only one groove and the sleeve is set by

inserting the taper pin in the proper hole in the sleeve. With the old arrangement shown in Fig. 2, the sleeve has only one hole and adjustments are made by slipping the taper pin through one of the grooves on the reamer shank. It is comparatively easy to make a mistake by this method because the sleeve conceals the grooves.

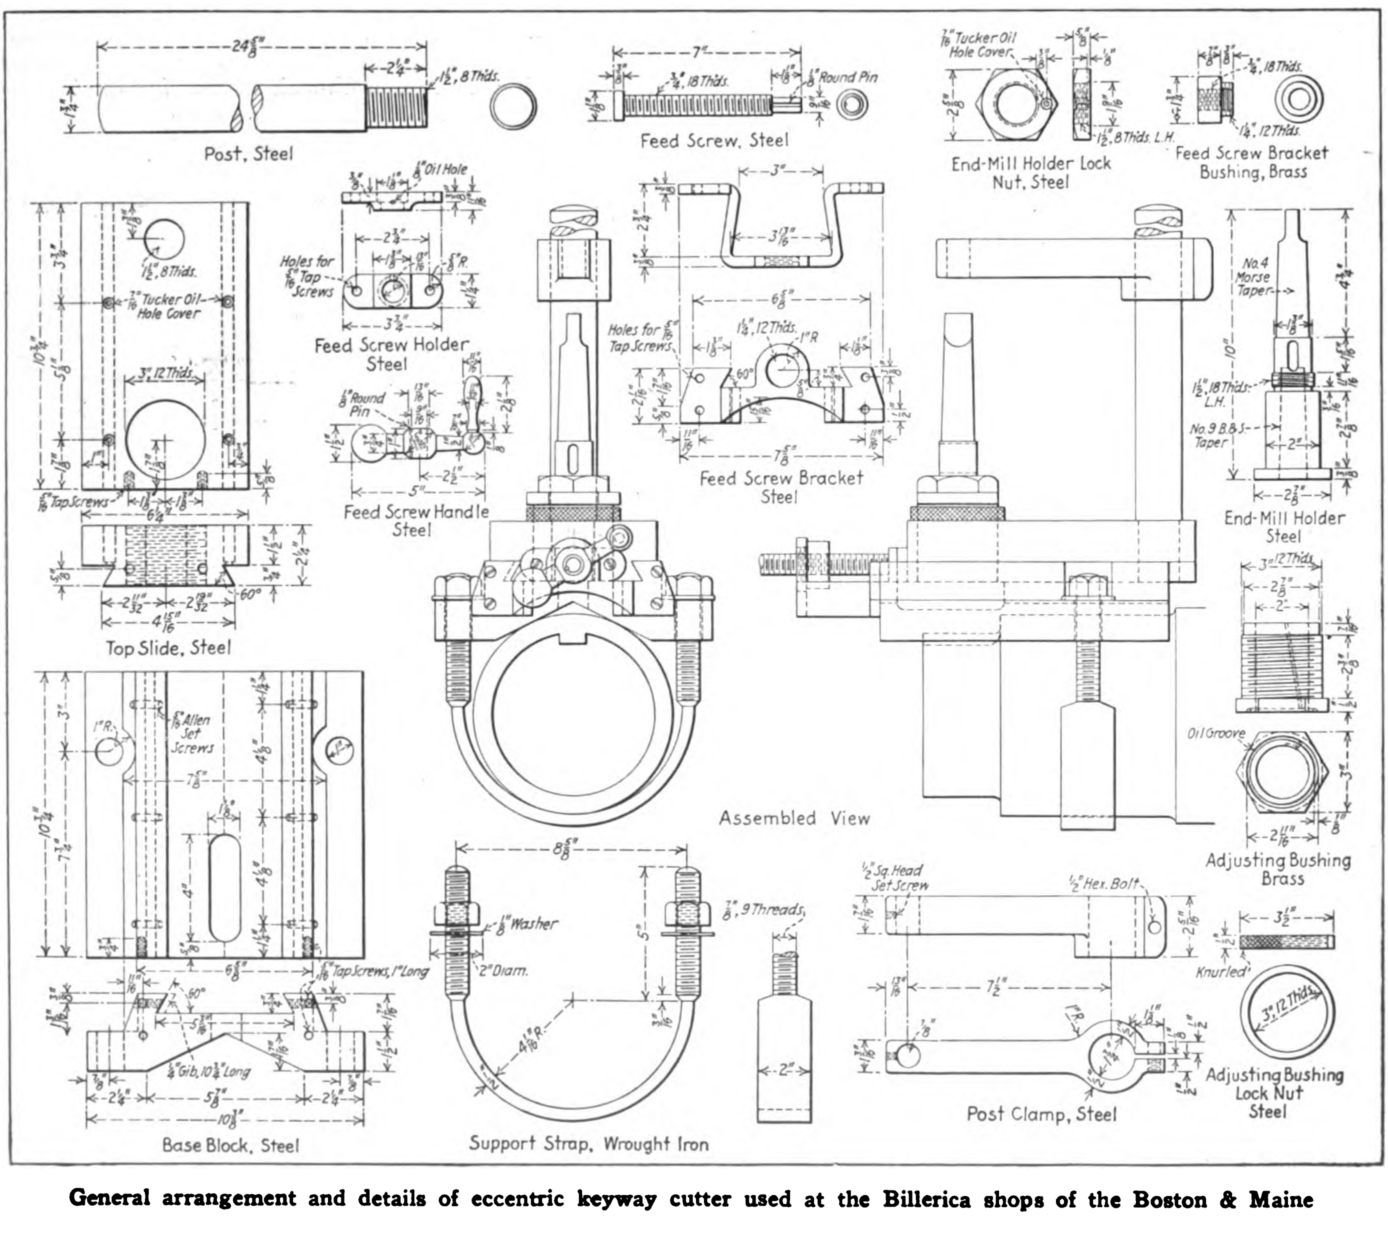
In the case of tapping holes for crown bolts, one tap is made for each line size and it is supposed to be run in flush with the sheet. This procedure, however, is not practicable for reamers as each one would be undersize after the first time it was sharpened. With this device it is only necessary after sharpening to fill the grooves on the reamer shank by electric welding and grind out a new groove to suit the sleeve.

Device for cutting keyways in eccentric pins

ONE of the troublesome jobs in connection with locomotive repair work is the cutting of new or the dressing up of old keyways in eccentric pins. To save time and labor in doing this work, there has been developed at the Billerica shops of the Boston & Maine an air operated portable key seat miller as shown in the illustration. The standard Morse taper shank is provided for attaching an air motor directly above the milling cutter. The motor is held firmly in place by a clamp attached to a 1¾-in. steel post. This arrangement eliminates vibration of the machine and gives a more smoothly milled keyway.

The end mill holder fits in the Morse shank. Fitted around the top of this holder is a steel adjusting bushing which passes through the top slide. The end mill is set to the proper depth of the keyway with this bushing and then maintained by setting the knurled lock nut. The feed is governed by the feed screw and handle at the front end of the device which moves the top slide in the base block parallel to the center line of the axle.

The tool is fastened to the axle by a ½-in. by 2-in. wrought iron U-shaped strap and two ⅞-in. tightening nuts, which draw the strap tight against the underside of the axle. The V-shaped surface of the base block of the tool provides for bringing the cutter on the center line of the axle. Provision is made for taking up all possible wear in the guides by two gibs which are adjusted by set-screws.



General arrangement and details of eccentric keyway cutter used at the Billerica shops of the Boston & Maine

Causes and prevention of pitting in locomotive boilers*

By C. H. Koyl
Engineer of water service, C. M. & St. P., Chicago

FOR many years the study of the cause of boiler pitting was handicapped by a confusion of terms between chemists and boilermen, the word cause meaning one thing to the chemist and quite another to the boilerman. The chemists were seeking for the cause of corrosion of iron, meaning by the term corrosion not only pitting and grooving in boilers but the rusting of iron in general. They sought not so much the physical causes which lead up to corrosion as they did the chemical conditions under which it takes place. They had in succession the oxide theory, the acid theory, the electrolytic theory, the biological theory, and others; but in 1922, by a continuous series of eliminations, they were finally able to agree that corrosion takes place only under water, or at least in the presence of moisture, and that its cause, or the chemical condition under which it takes place, is the presence of hydrogen ions in the water.

On the other hand the boilerman, who knows little about hydrogen ions, wants to know whether pitting is due to something in the boiler feed water, and if so, what; or to the kind of metal of which the boiler is made; or to the temperature of the feed water, or to the number and location of the injectors, or what not; always meaning by the word, cause, something under the control of the man who made the boiler, or of the man who runs it.

Accepting the statement on which all leading chemists have agreed, that pitting can take place only in the presence of hydrogen ions in the water, there yet are two distinct methods by which water becomes charged with hydrogen ions—first, by adding acid; second, by electrification. This tallies exactly with our statement of last year, founded on observation, that there are two kinds of pitting in locomotive boilers, one due to acid and the other due to electric action. But, for the boilerman, there are seven or eight conditions of water or metal to be guarded against under these two general headings.

Pitting caused by acids

Pitting by sulphuric acid, which in this country can best be observed in the vicinity of the eastern coal mines, is very characteristic in locomotive boilers. It always starts about the firebox, where both iron and water are the hottest. It shows its first effect where the surface of the metal has been weakened by bending, punching or heavy hammering, and gradually works forward, so that in the course of time it may reach the front of the boiler. Therefore, from our point of view, water contaminated by the eastern coal mines is to be avoided as one cause of pitting.

Water from swamps and stagnant ponds, and decomposing sewage, none of which are acid in the cold, will yet pit boilers because they are converted to acids by the heat of the boiler. Therefore, to the boilerman, water from these sources are to be avoided as a second cause of pitting.

When the acid in the water is very weak, it has been noticed that the only parts of the boiler affected are those where the smooth surface of the metal has been broken or weakened by rough handling. It may be by scratching a flue as it is worked through the flue sheet; it may be by excessive rolling near the flue end; it may even be by rusting in the open air; but whatever the cause of breaking the hard smooth finish on the steel, it is to be avoided as a third cause of pitting.

Every one knows that the chemical action of acid can be prevented by neutralizing the acid by lime and soda-ash before the water goes to the boiler. On the C. M. & St. P. there is some pitting due to the above causes, but not much. Most of our pitting is on the electric order.

Pitting caused by electric action

Electric pitting in locomotive boilers is also very distinctive in character. It commences at the front end of the boiler where the water comes in, and follows the course of the water toward the firebox though the pitting seldom reaches more than half way back. In its early stages it is found only on the three outer rows of flues, on the front belly plate, and on the front ends of the flues near the flue sheet, but it gradually works toward the firebox.

Also, this kind of pitting is found only in boilers fed with water rich in sodium sulphate or sodium chloride, say 20 grains per gallon as the water goes to the boiler. These alkali salts are chemically neutral to iron at boiler temperatures, but are good electrolytes, that is, they make easy the passage of an electric current through the water; and these circumstances are the starting point for the belief that in this case the hydrogen ions necessary for pitting are the result of electric action.

Furthermore, of late years it has been apparent that electric pitting is of very small amount unless there is oxygen in the water. The reason for this is that in electric pitting the atoms of metallic iron must be dissolved in the water, and since water can hold in solution only an infinitesimal quantity of iron the water would soon become saturated and the pitting cease unless something in the water continuously combined with the iron to take it out of the water and leave room for more iron. This something is oxygen.

Causes and prevention of electric pitting

Therefore, for electric pitting there must exist simultaneously three causes or conditions—electric potential from the iron to the water, alkali electrolyte in the water, and oxygen in the water. If we can eliminate any one of these three conditions we can prevent electric pitting.

For practical purposes we may at once give up hope of getting rid of alkali water, because on the Great Plains between us and the Rocky Mountains there are many thousands of square miles with no other kind of water. It is true that I can show you in print, and signed by a famous man, the proposal to evaporate all this water and then condense it for locomotive use; and it is also true that the chemist of a leading railroad proposed about the same time to freeze all this water and store the ice for

* Abstract of a paper presented before one of the Master Mechanics' staff meetings of the Chicago, Milwaukee & St. Paul.

locomotive use. Each method would give us nearly pure water, yet either would cost too much. Therefore our efforts for prevention of electric pitting must be limited to the elimination of either electric potential or oxygen.

It is a known fact that between any two pieces of metal under water there is a tendency to an electric current if they differ in chemical constitution or in physical condi-tition even the smallest amount. Steel is composed of iron and several other elements and under high-speed manufacture cannot possibly be absolutely uniform in texture and in hardness over the surface of even one flue. There are bound to be spots from which small electric currents tend to flow to other nearby spots, and if they do flow, they take atoms of iron with them, and the result is holes or pits in the steel. This kind of action is known as electrolysis, and its cause is inherent in the steel.

Other metals, such as wrought iron and copper, are more uniform in texture than steel, and both have been tested in boilers and found to pit less. But in addition to the greater cost, there are other reasons why neither of these metals has come into general us for boiler sheets or flues.

It has also been found that if an electric battery is carried on the engine, with its positive pole connected to the water and its negative pole to the boiler shell, the water can be kept at a higher electric potential than the metal which eliminates electrolytic currents and pitting is stopped.

But all these more or less expensive or cumbersome remedies have been held in abeyance because it became evident a few days ago that we had not learned all that was to be known about electrolytic pitting. As already stated, this kind of pitting shows principally on the front half of the boiler. But presumably the steel is of the same kind from one end of the boiler to the other, and, if electrolytic pitting were controlled entirely by the quality of the steel, pitting should be uniform throughout the boiler. Also the flues at the hot end of the boiler are held in the flue sheet by copper shims, and if, pitting were due entirely to difference of metal, then steel flues should pit most rapidly in contact with copper; but they do not.

Eliminating oxygen in the feedwater

Evidently the presence of alkali water and of the electrolytic difference of potential between hard spots and soft spots on steel, and between steel flues and copper shims are not enough to produce pitting. It is just as evident that the third and necessary factor is in the water when it comes through the boiler check valve, and is used up when the water is half way back to the firebox. The discovery and proof of this third factor is the key to the prevention of electrolytic pitting.

At first it was thought that a difference of electric potential between the boiler metal and water existed when the water entered the boiler, and might be sufficient to last until the water was half way back, and thus explain pitting on the front half of the flues and none on the back half. This electric charge, positive on the metal, negative in the water, does exist when the water has passed the boiler check valve. It is always present while the injector is in operation, but I have never found it of sufficient force or quantity to account for the pitting in the front half of the boiler. The phenomenon will require further study because it certainly has some effect on the pitting, but I am convinced that it is not the controlling factor.

The one remaining active content of the water as it enters the boiler is oxygen, and we have enough proof now to enable us to say that this small amount of oxygen, one part per hundred of the water by volume and only twelve parts per million by weight, is the factor which insures pitting in the front half of the boiler; and that there is seldom electric pitting in the back half of the boiler because there is not enough oxygen to last.

We have been a long time making this discovery because we all thought that electrolytic potential in the presence of alkali sulphate was enough, and it was only when we separated acid from alkali pitting and found the alkali pitting is confined to the front of the boiler, that we were led to study the influence of oxygen in this kind of pitting. The proof is complete when we find that the pressure of an open feedwater heater, which nearly eliminates oxygen, is sufficient practically to stop pitting in stationary boilers. Feedwater heaters for locomotives are new in the world but they are in successful use, and some of them are of the open type so that the oxygen can escape while the water is being heated. On a locomotive equipped with such a heater we have conducted a series of daily tests for two months, and find that on the average, 80 per cent of the oxygen is eliminated.

A locomotive feedwater heater saves 10 per cent of the fuel and water, and pays for itself in a year or so; and it will not be any added expense to get rid of oxygen and thus prevent nearly all electric pitting. Therefore, I say with confidence that the days of electric pitting in the Northwest are numbered.

Cleaning triple and distributing valves with kerosene*

By H. G. Myrick
Air brake foreman, Chicago & Alton

After a number of years experience in air brake repair work, the writer has seen the process of cleaning feed valves, distributing valves and triple valves develop through several stages. Both gasoline and kerosene have been used quite extensively and at the present time steam seems to be the most popular. However, for most practical purposes the writer prefers to use kerosene, or what is generally known as coal oil.

Unless gasoline is used with care and the "fire is cut" with engine oil or some other substance, it will blister the hands and arms of the workman. It is also considered to be a fire hazard and, furthermore, its cost is greater than kerosene. On the other hand, it does the work in a satisfactory manner, as it cuts the grease which often accumulates in the main piston bushing and various movable parts of a triple valve. Gasoline also performs the work much quicker than kerosene and it evaporates entirely when air is used to blow out the triple valve after it has been washed. Gasoline will evaporate if by any chance some should be left in the triple valve after it has been assembled and then forced into the test rack during mounting and testing. Kerosene tends to accumulate in the pipes, joints and elbows of the test rack which deposits the graphite lubricant behind fins and in crevices.

Steam is about as dangerous as gasoline on account of the liability of the workman being scalded. Triple valves have rubber and leather gaskets which will not stand the heat of live steam. In order to clean a triple valve it is necessary to remove the check valve case and the cylinder caps, and replace worn-out gaskets, including the rubber seat in the emergency valve. It is, therefore, impossible

* Abstract of a paper read before the St. Louis Air Brake Club, December 12, 1924.

to clean triple valves with steam in the same manner as one would clean the feed valve on a locomotive.

Proper facilities must be provided in order to use steam for cleaning purposes. Due consideration should also be given to the fact that considerable time is consumed in steaming out, cooling and extra handling. If the work is done in a small room, steam will cloud the room, making it unsafe to work in. In repair shops where from 30 to 40 triple valves are being handled each day, the problem of eliminating extra handling is an important one. Tests have shown that the steam does not loosen any of the bushings; but instead of having a dry heat, a wet heat like boiling water will result.

Some men will go to extremes in using kerosene and get so much oil soaked into the casting that it is practically impossible to blow it out. It works up into the slide valve bushings, cutting the dry graphite lubricant, which eventually gets into the test rack.

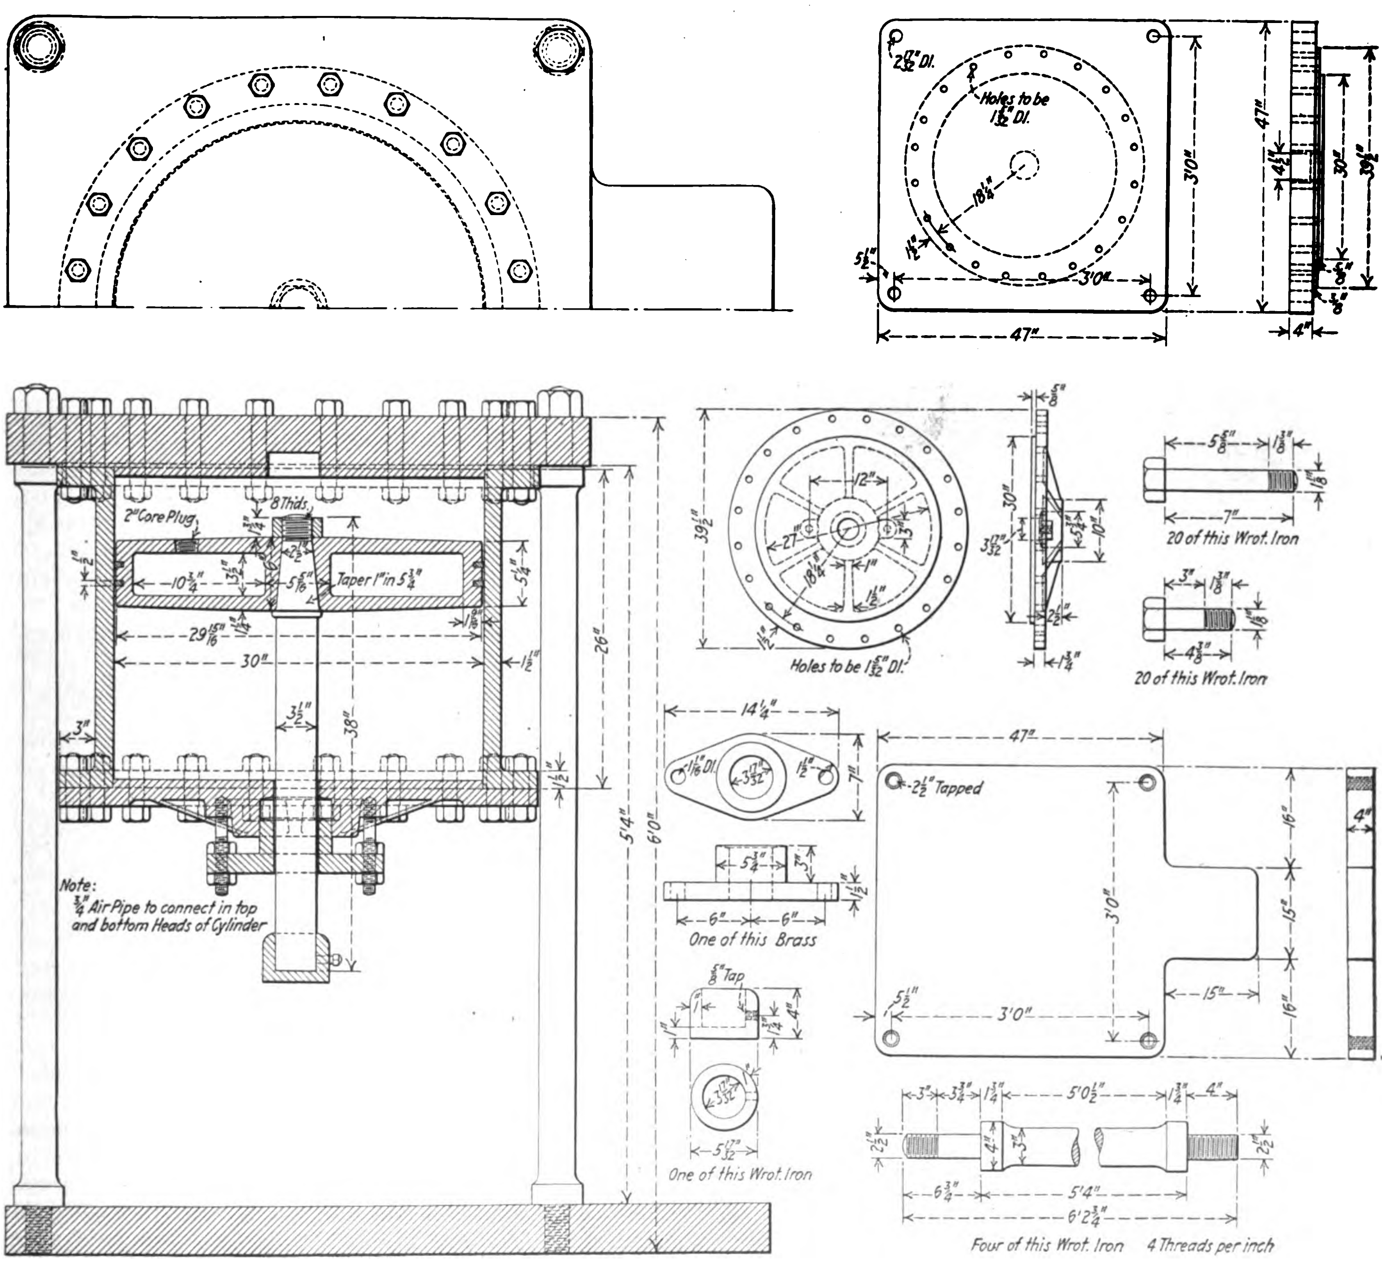
It has been found that by using a bucket or tank with sufficient kerosene in it to cover half the piston, that the oil will last the average man for one day. The bucket or tank can be emptied each evening and clean oil obtained the next morning.

A soft rag should be used to wash off all parts placed in the kerosene tank. The triple valve body should be clamped in a wire and sufficient oil squeezed from the rag to clean it out. An oak stick ¾ in. square and 14 in. long should be used to push the rag into the slide valve bushing. It does good work and protects the fingers of the workman. After washing, wipe out the oil and blow out with air, repeating the operation until the valve is thoroughly dried out. It is good practice to have an oil squirt can filled with gasoline available to flush the air passage in K and L type triple valves.

Pneumatic press for driving box shells

By E. A. Miller

A CONVENIENT type of pneumatic press that can be used to good advantage for such work as pressing in driving box shells or rod bushings is shown in the drawing. Its construction is comparatively simple, con-



Drawing showing the assembly and various parts of the pneumatic press

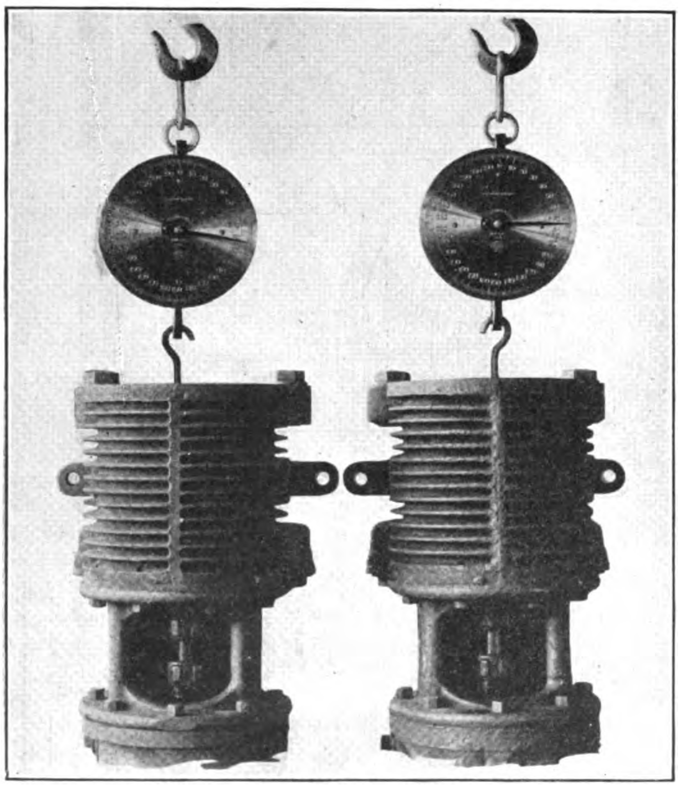
sisting essentially of a 30-in. by 24¾-in. air cylinder, a plain cast steel base and top casting to which the air cylinder is bolted. The top casting is supported on four columns, 3 in. in diameter and 5 ft. 4 in. high.

Power is furnished for pressing by admitting compressed air above the piston. Connections are provided in the top and bottom heads of the cylinder for a ¾-in. pipe which is connected to the shop air line through two control valves, one of which is for lowering the piston and the other for raising. The piston rod is 3½ in. in diameter and is secured to the piston in the usual manner, except that the shank is tapered 1 in. in 5¾ in. This distributes the pressure exerted on the piston over a greater area than would otherwise be the case if the shank were turned without a taper and the pressure of the piston were exerted entirely on the shoulder of the piston rod, which extends down through the bottom head where it serves as the ram. A shoe of wrought iron is placed on the lower end of the ram to take up the wear.

Air compressor maintenance*

THE methods of maintaining locomotive air compressors at railroad shops and enginehouses are important because on them depends the efficiency and subsequent service life of the compressors as well as the cost of the maintenance work itself.

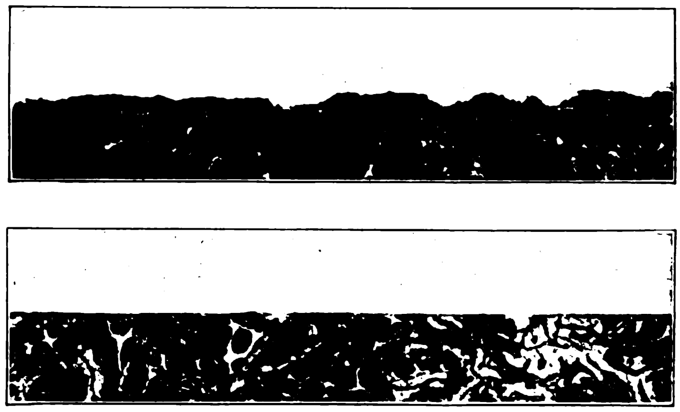
At the present time worn cylinders are commonly re-



The ground compressor (right) showed 11 per cent less pull required to lift the piston, ring and rod assembly than the bored compressor (left)

conditioned by boring, although a considerable number of grinding machines of different types have been installed within the past two or three years and have proved successful for handling this operation. When ground, the resulting cylinder surface is much superior to that obtained by boring, both in smoothness and accuracy. As the grinding wheel is composed of many thousand cutting particles it removes the necessary metal with a minimum pressure against the cylinder walls. The comparison between bored and ground surfaces afforded in two of the illustrations is significant. The superior smoothness of the ground surface means a correct seating of the rings from the start. Owing to the light pressure of the wheel against the cylinder walls, the grinding process is not affected by thick and thin walls, hard spots, etc., with the result that grinding will produce a straight and round hole without cutting away an excessive amount of stock. This minimum removal of stock means that air compressors may be reconditioned many times by grinding than is possible by boring.

Although grinding is generally admitted to be superior to boring, the factor of cylinder misalinement may still



Unretouched microphotograph of cylinder wall section, bored (above) and ground (below) which shows the smoothness obtained by grinding

be present to detract from the highest air compressor efficiency. The present common method of boring cylinders necessitates their removal from the center castings. Each cylinder or pair of cylinders is set up and bored separately and assuming that accurate centers are obtained in boring, the cylinders may be slightly out of line when reassembled either to their original or some other center casting. It should be borne in mind that taper and out-of-round conditions in the cylinders accentuate misalinement as does also the failure to draw the gasket down evenly. Misalinement not only adds to the internal friction but makes it necessary to exert considerable pressure on the stuffing box packing to prevent leaks. The correction of cylinder misalinement in air compressors is proving a real problem on some roads which have been compelled to adopt strenuous methods to secure accuracy in this detail of maintenance. The effect of cylinder misalinement is clearly shown in the drawing.

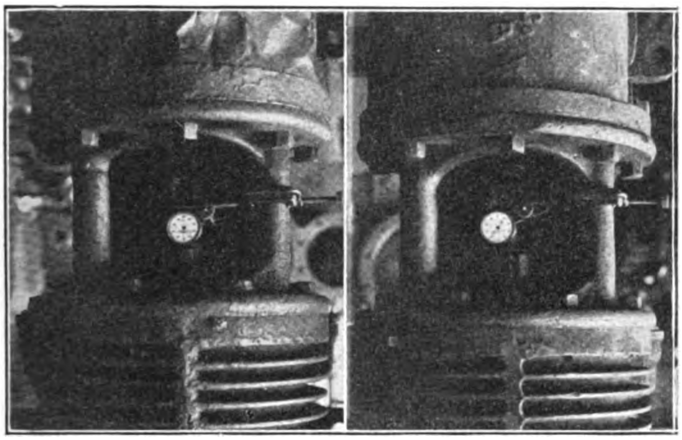
Air compressor tests

The following tests were conducted, using Westinghouse 9½-in. air compressors. Both bored and ground pumps were reconditioned to the same oversize with the same piston clearance and ring gap. The bored compressor was reconditioned in a railroad shop and when measured with inside micrometers showed 0.004 in. out of round and 0.009 in. taper in the steam cylinder, while the air cylinder was 0.008 in. out of round with 0.011 in. taper. In the ground pump both the steam and air cylinders were measured showing that they were straight and round within 0.001 in. New pistons and rods were used, the pistons being turned 0.009 in. smaller than the

* The facts pertaining to the tests described in this article were obtained from the Micro Machine Company, Davenport, Iowa.

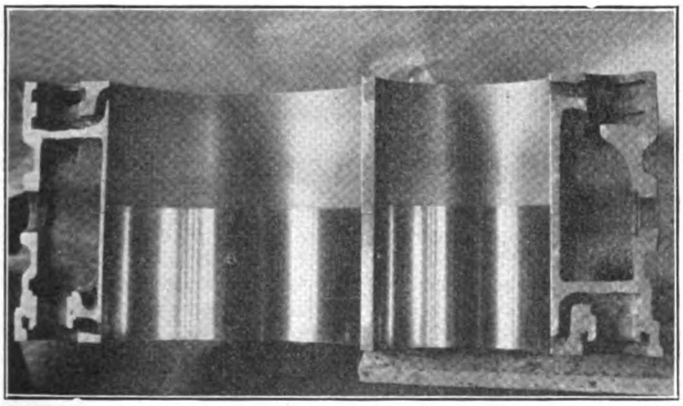
smallest diameter of the cylinder, or 0.001 in. for each inch of cylinder diameter.

In testing for alinement the pistons were assembled in the compressors without rings and an indicator was clamped to the center casting playing on the piston rod as illustrated. In pushing the pistons back and forth the indicator showed a misalinement of 0.010 in. on the bored pump and less than 0.001 in. on the ground pump. The piston, ring and rod assembly of both compressors weighed 57 lb. The pistons, rings and rods were then assembled to the cylinders, piston rod packing and stuffing box nuts being omitted. With the compressors in a vertical position a spring scale was attached to the piston and a steady upward pull exerted, also shown in one of the illustrations. The bored compressor pistons pulled at 82 lb. (or a frictional pull of 25 lb.) and the ground compressor pistons pulled at 73 lb. (or a frictional pull of 16 lb.). This showed a difference of 9 lb. or 36 per cent less frictional resistance for the ground compressor.



How the test for cylinder misalinement was made

The compressors were tested on a standard railroad test rack under pressure. In order to obtain conditions as nearly equal as possible the same steam heads were used on both compressors. The steam line carried a pressure of 135 lb. The initial test was conducted to determine the highest pressure that could be reached with the orifice closed, and the number of strokes necessary to maintain this pressure. The ground compressor reached a maximum pressure of 120 lb. and maintained this pressure with 19 strokes per minute. The bored compressor reached a maximum pressure of 115 lb. and maintained this pressure with 38 strokes per minute. This showed a saving of 50 per cent in strokes with the ground as compared with the bored compressor as well as demonstrating an ability on the part of the ground compressor to attain a higher air pressure.



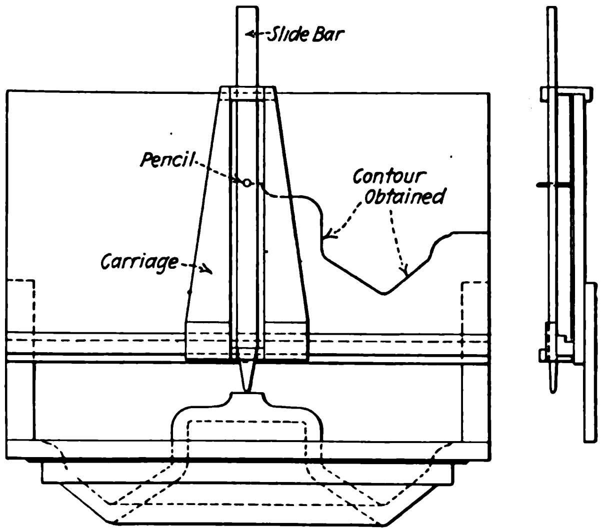
Surface comparison of bored and ground sections

The second test was conducted to determine the necessary strokes and time required to pump up to 100 lb. pressure with the air tank empty and the orifice closed. The bored compressor required 376 strokes and 4¾ min. while the ground compressor required only 320 strokes and 4½ min. The ground pump showed a reduction in strokes of 14.7 per cent and in time of ¼ min.

A third test was conducted with the 11/64-in. orifice open. The ground compressor reached a maximum pressure of 55 lb. in the drum and maintained this pressure of 104 strokes per minute. The bored compressor reached a maximum pressure of 50 lb. and remained at this pressure with 108 strokes per minute. During the test it was necessary to tighten the stuffing box nuts three times to prevent leakage with the bored compressor but this was unnecessary in the case of the one with ground cylinders. In order to ascertain the comparative difference in pressure of packing on the piston rods the heads were removed and it was found that the piston in the ground compressor could be lifted easily by hand and would drop by its own weight, while the piston in the bored compressor could not be removed without the use of a chain block.

Checking contours of cylinder head castings

SOMETIMES an engineman forgets that the cylinder cocks will let water out of the cylinders more economically than by way of the front cylinder head. There are also occasions when the rod gang in the repair shops makes a mistake and when the cylinder head is blown out, it is a difficult matter to place the blame where it belongs. A number of investigations have shown the existence of interference between the piston and cylinder head, due to incorrect contours of the cylinder head casting. In order to protect the stores department from accepting castings having wrong contours, the mechanical engineer's office had the pantograph arrangement shown in the sketch made so that the contours could be properly checked.



Apparatus by which inaccuracies in the contour of a cylinder head casting can be determined

This device, which was made in the pattern shop, con-

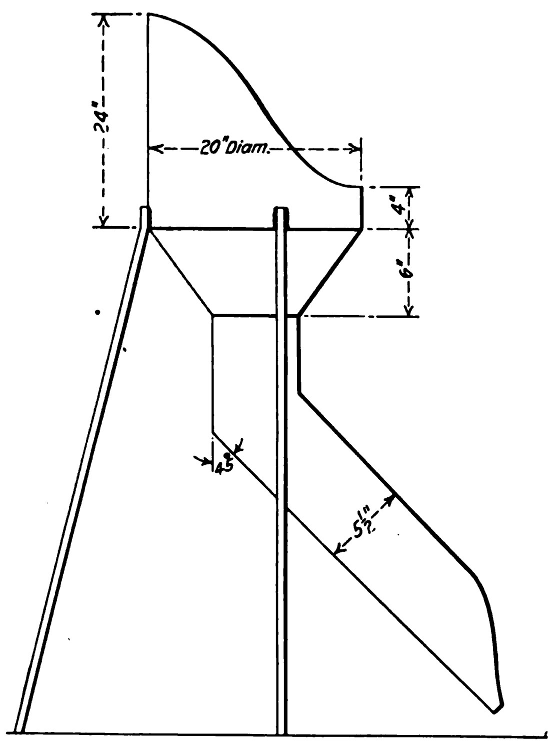
sists of a base board to which a sheet of drawing paper is fastened, and a carriage equipped with a slide bar and pencil. The carriage, shown in the sketch, carries the slide bar which moves vertically in its guides. The lower end of the slide bar is tipped with a metal point which is kept in contact with the contour of the casting as the carriage is moved while the check is being made. A pencil for scribing the contour line on the drawing paper is inserted through a hole located near the center of the slide bar.

The carriage is free to move in a horizontal direction only and the slide bar can be moved only in a vertical direction. As the carriage is moved across the face of the base board, the slide bar moves up and down as guided by the contours of the cylinder castings. These combined movements give the resulting contour line which is scribed by the pencil on the drawing paper.

Wash-out trough for the enginehouse

By Joseph Smith

THE locomotive wash-out trough shown in the sketch has given such excellent results that it has superseded the troughs that were formerly used in at least one shop. The upper portion is made of ⅛-in. steel plate, cut to form a tapering section as shown. This

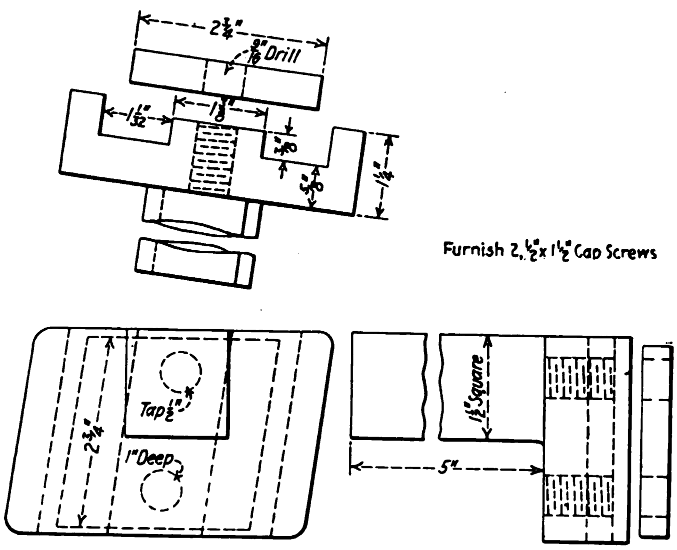


The use of this trough when washing out a locomotive has added materially to the comfort of the men

is welded to a section shaped like the frustrum of a cone while the outlet portion is made from a discarded superheater tube which is cut for the shape shown and welded to the funnel. The length of this trough can be made to suit local conditions, but it should be long enough to extend over the side of the engine pit. The trough is supported on three legs made of ¾-in. round iron, flattened out at one end and welded to the body of the trough. Two of these troughs are required, one at each front corner of the mud-ring.

Double tool holder for grooving locomotive tires

THE usual practice of cutting the tire grooves in a segmental ring is to machine them one at a time on a boring mill. In order to reduce the time required for this operation, a double-tool holder has been designed which is shown in the accompanying illustration.



Tool holder for cutting two grooves at one time in a locomotive tire

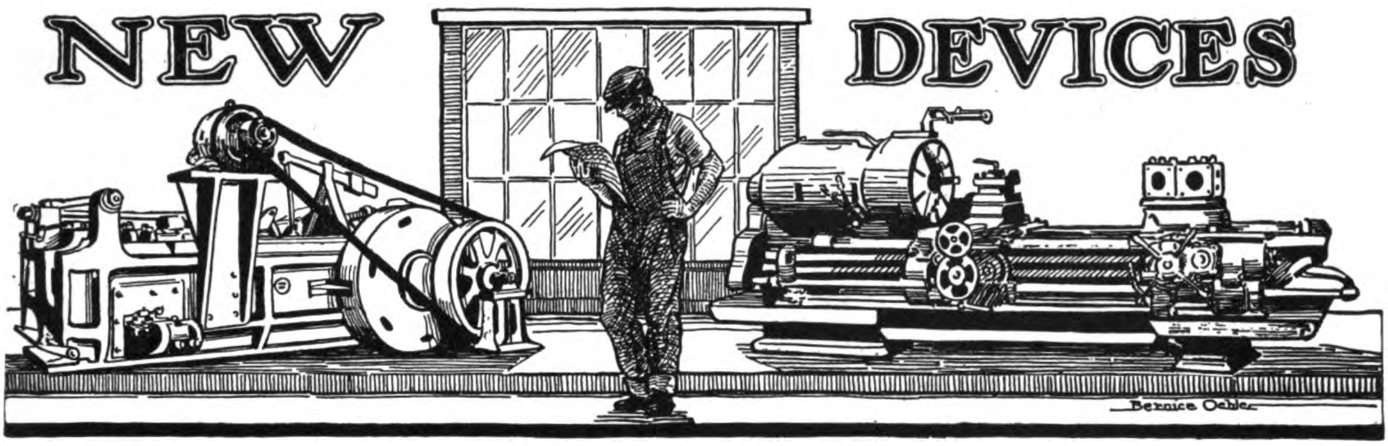
It will be noted that it is simple in construction and that it is so designed that the cutting tools are securely held in position. This allows the use of any high speed cutting tool which facilitates the depth and speed of cut.

DeWitt Rapalje, engineer of the Railroad Insurance Association, New York City, believes that many "no smoking" signs have, under existing conditions, about the same deterrent effect on railroad employees as they would have on a locomotive if tacked up on the front end of its boiler. In a paper prepared for the National Fire Protection Association, he says:

Locomotives often do a lot of smoking, but there is a more promiscuous smoker and a greater fire hazard on the railroads, and that is the careless employee. Matches and smoking, among the known causes reported annually, average over 300 fires and about half a million dollars of railroad property burned. No doubt many of the fires of "unknown" origin may belong in this group. Efforts to reduce this hazard which consist only of posting "No Smoking" signs at every conceivable point are frequently misdirected and are of about as much value as a fuel economy campaign would be which consisted of tacking a "No Smoking" sign on the front end of every locomotive.

Railroad employees generally have rough and dirty work to do as their daily task and efforts to convert them all to the non-smoking class are bound to meet with scant success. Most of them want to smoke, and they do so regardless of all the signs.

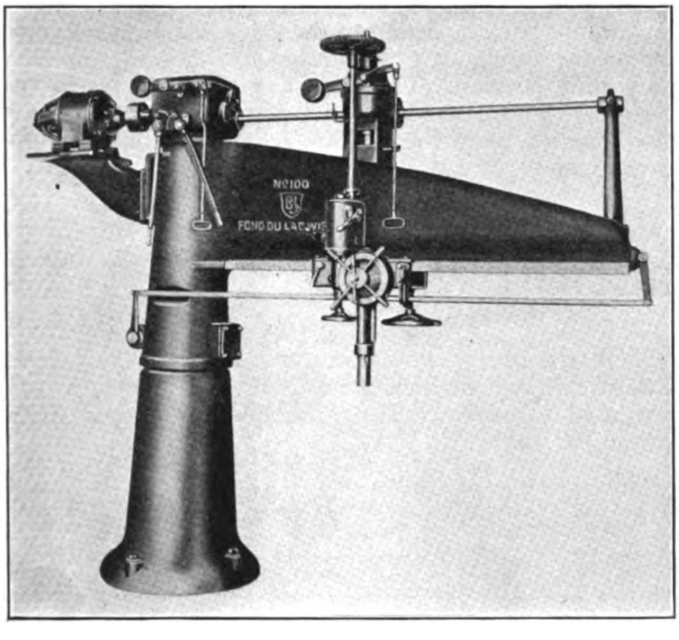
Smoking is a general habit and should be provided for by managements for employees the same as facilities are provided for passengers who smoke on trains and at stations. Provide safe and suitable smoking rooms and this serious fire hazard can be controlled. Rules against smoking can be enforced if they are applied only at the hazardous spots. The railroad record-room is a case in point. Fire inspectors are constantly reporting evidence of smoking in the typical record-room where large quantities of paper files are stored. This room generally affords one of the worst places for a cigarette butt or burning match to be left to its own inclinations. The file clerks smoke in these rooms because they can do so there without detection, while the office in which smoking might be safely indulged is filled with smoking prohibited signs.



Six-foot plain radial drill

THE 6-ft. plain radial drill shown in the illustration was designed to meet the present day requirements in boiler, car and locomotive shops. It is particularly adapted for drilling material such as tank and boiler plates. It has been designed to give ease of operation, by a convenient location of the hand wheels, lever, etc., and lower power consumption, because of the short and simple drive connections between the motor and the drill spindle.

The arm is of the hollow, box-type construction and is



Drill press designed for plate work with the control levers centralized

well ribbed. It has a movement of 360 deg. about the column. It revolves on the column in roller bearings, and a large size ball thrust bearing is used to carry the weight of the arm, thus minimizing the force necessary to move the arm to the desired drilling position. The arm is also provided with a positive opening and closing cam actuated clamp for holding it to the column and is operated by a lever mounted on the head, which is within easy reach of the operator at all times.

The motor drive is connected to the drive shaft of the speed box by means of a silent flexible Grundy coupling. The motor bracket is of the box type of construction and is adjustable to suit the different motors which may be used. Tapping can be performed on this machine by installing a reversing motor provided with a magnetic brake and control.

The speed box provides eight changes of speed for the spindle. The shafts are mounted on large size ball bearings. The sliding gear system is used to change the speeds and generous size bronze shifter shoes are employed to shift the gears. The gears run in heavy oil and are entirely enclosed by the speed case proper, the cover of which is easily removed for inspection purposes and repairs.

The spindle head is a rigid casting, well ribbed, and having long and narrow guiding ways which insure correct alinement at all times. The head is moved along the ways of the arm by means of an angular rack, worm, and generous sized hand wheel. The head can be clamped to the arm at any desired location.

The spindle is made of high carbon steel and runs in bronze bearings and is liberally supplied with oiling facilities. The thrust is taken by a large capacity ball bearing. The spindle is driven by means of a hardened steel worm and a bronze worm wheel, the worm being connected to the speed box by a shaft having a continuous keyway on which the worm slides. The worm runs in an oil bath and is mounted on ball bearings, one of which is of the double row deep groove type to take the thrust. The spindle proper has a double keyway on which is mounted a hardened steel jaw clutch, which meshes with a clutch fastened to the bronze worm wheel. The clutch on the spindle proper is shifted by means of bronze shifter shoes. The shifting lever for operating this clutch is directly in front of the operator. The entire driving mechanism is enclosed in a dust proof housing. One of the important features of this machine is that the spindle travels directly in the vertical center of the arm. By this construction all twisting strains on the arm are avoided.

The drive to the feed box is taken from the main spindle through spur gears. The drive pinion is made of steel and runs in a bronze bearing and is held in place by means of thrust washers. The driving gear is directly connected to the feed box mechanism. The pinion and gear are entirely housed but are easily accessible.

The feed box is a self-contained unit. The standard drive key construction is used to obtain the different feeds, of which there are six, having a range that is adequate to meet all needs. The changes are made by means of a

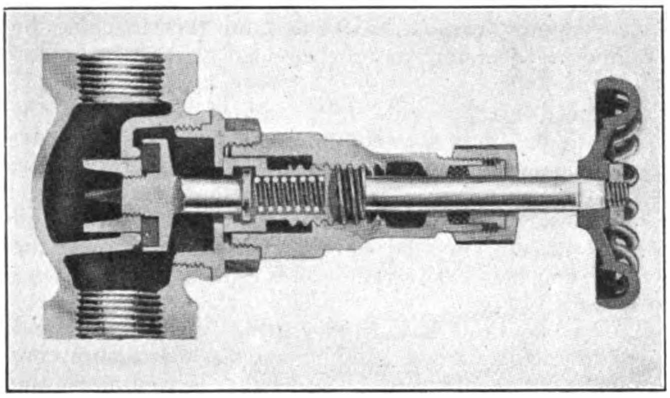
graduated dial showing the various feeds obtainable. All the shafts run in bronze bearings. A positive jaw clutch is provided for disengaging the feed.

The feed to the drill spindle is obtained through a worm, worm wheel, rack and pinion. The worm is of hardened steel and the end thrust is taken by a ball thrust bearing. The worm wheel is of cast iron and runs directly on the pinion shaft. A large friction clutch of the multiple disc type is used for engaging the power feed. A hand hole is provided for adjusting the friction clutch. The two handles of the pilot wheel when pulled toward the operator engage the feed, and when pushed away, disengage it. A hand feed wheel is also provided on the worm shaft. The feed pinion is cut directly on the shaft and is liberal in width and length. The rack is made of steel and securely fastened to the spindle sleeve.

The machine will drill holes in solid steel up to 2 in. in diameter. A 7½-hp., 1,200 r.p.m. motor is recommended. This machine is manufactured by the Giddings & Lewis Machine Tool Company, Fond du Lac, Wis.

Self seat brass valve

THE Ohio Injector Company, Wadsworth, Ohio, has recently received patents on and placed on the market a brass body valve designed for steam working pressure up to 200 lb. The principal feature of this valve is that the seat and disk are always brought into contact and held together by the same pressure, and it is so designed that this pressure can never be great enough to injure these parts. This action is altogether independent of the pressure applied to the hand wheel and it is therefore impossible to destroy the seating qualities of the valve by rough and careless operation. For this reason this valve is particularly adapted to serve where unskilled labor is employed and it also increases the life of the valve seats.



Ohio valve designed for steam pressure up to 200 lb.

Among the points of advantage which are claimed for this valve are that its area is not restricted by the extension of the stem into the seat opening; the valve body is of greater strength owing to the fact that there are only three openings in it. This valve is designed in such a manner that it will function when mounted in any position, and the perfect seating of the valve disk is not dependent on the spring or gravity to insure the disk coming to a seating position. The perfect operation of the valve is said not to be affected by the spring losing its temper or being omitted altogether. This feature is conducive to its continuous operation.

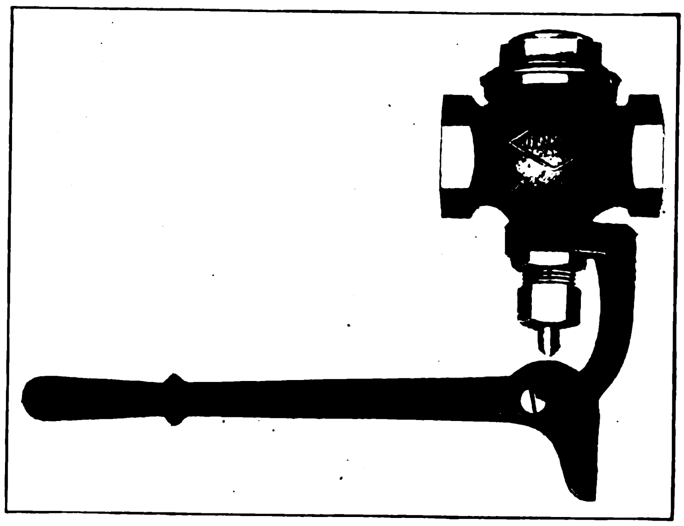
Jenkins rapid action valve

A RAPID action valve designed to fill a need for a valve that can be opened and closed instantly without water-hammer, and that will automatically stay open without the aid of set screws, locking devices or other appliances, is manufactured by the Jenkins Brothers, New York, whose specialty is all types and sizes of valves.

The hand lever, when given a pull of a quarter turn, bears on the end of the spindle which forces the disc off the seat, thus opening the valve. The lever alineing with the spindle positively holds the valve open. A slight pull on the lever, however, will throw it out of alinement with the spindle and the disc is then immediately forced onto the seat. The closing of the disc on the seat is regulated to avoid water-hammer; this being accomplished by the combination of a spring, piston, cylinder and water pressure. The avoidance of water-hammer is always desired in any installation, especially in shops and offices where the noise will annoy those at work.

The valve is made from a bronze mixture and is fitted with the Jenkins renewable composition disc. The spindle is made of steel, the yoke is steel forged, and the lever is enameled. The end of the spindle and the cam on the lever are especially hardened to prevent wear, which increases the life of the valve, which is an important feature in valve maintenance.

There are many uses for a rapid action valve in the modern railroad enginehouses, yards, and shops, it has been used to advantage, for example, on water supply lines in car yards.



Rapid action valve which automatically stays open without the aid of any other device

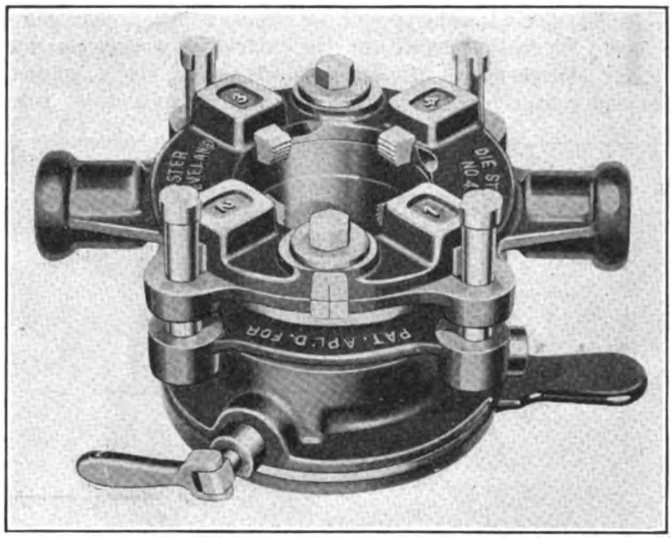
Die stock for cutting pipe threads

An easy cutting, receding die stock recently placed on the market by the Oster Manufacturing Company, Cleveland, Ohio, has several features of interest. Its capacity is one-inch to 2-inch pipe and it is made in both the plain and ratchet types.

One of the special features of this cutter is the lead on the dies which enables the operator to start them quickly and easily. A scientifically worked out cutting angle or rake brings the efficiency of the cutting edge of the dies to a maximum so that the teeth will tool out the metal with the least amount of pull on the part of the operator.

The die head of the tool is constructed so as to be quickly and easily adjusted to cut oversize or undersize as well as standard threads. The lead screw is protected from dirt and chips by a chip shield. This tends to lengthen the life of the lead screw, which is important to a tool of this type.

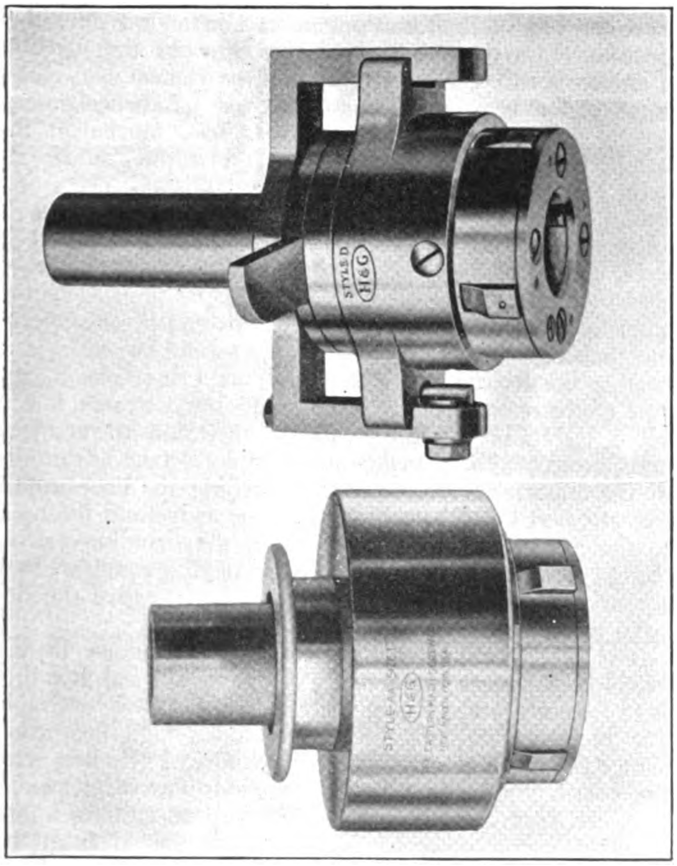
A self-centering chuck is standard equipment with the tool but it can be supplied also with bushings and set screws. The advantage of the chuck is that there are no set screws to adjust or extra bushings to carry.



The Oster easy cutting die stock uses a new type of dies

Self-opening die heads for screw machines

A SELF-OPENING die head for automatic screw machines and for threading on drill presses is the latest development of the Eastern Machine Screw Corporation, New Haven, Conn. Referring to the illustration, the upper view shows the new style AA die head designed for threading on a drill press, National Acme automatic threading machine, etc. The lower photograph shows the new style D double-drive die head especially designed for service on Brown & Sharpe automatic screw machines.



The style AA die head at the left specially adapted to machines where the die rotates and the stock does not—The style D die head at the right is provided with a double drive feature

The style D head is provided with two arms from the floating shank instead of one, which prevents any possibility of the head being thrown to one side, due to the action of threading. Both the arms and the bearing surfaces of the extensions from the shells are ground so that the drive is equally distributed, both to the top and bottom. The head is self-contained in that an accurate adjustment for the length of thread is provided on the upper arm. These heads are designed to provide a wide range of thread specifications and at the same time to simplify the cam layout, set up and general operation of the machine. It is also adaptable to Cleveland automatic screw machines.

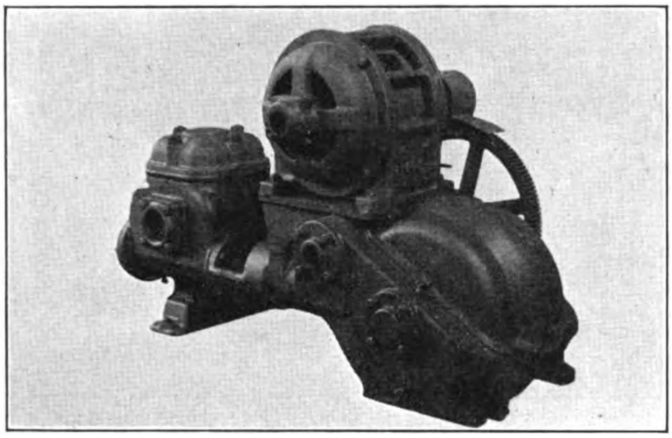
The outer sleeve of the style AA head is provided with a spool at the back to take a simple yoke. It is so designed that when the threading spindle is drawn back after a thread has been cut and the backward motion of the yoke arrested by means of a stop, the die head is automatically closed. As the die spindle advances during the threading operation, the length of thread cut is determined by a stop which arrests the forward motion of the yoke, thereby holding back the outer sleeve and causing the die head to trip.

The tripping which is of the pull-off nature is quite sensitive in its operation and makes it possible to govern the length of thread to a small fraction of the pitch. This arrangement provides a safety feature against any possibility of the head starting to thread short bar ends and refusing to let go. Only the simplest form of sliding yoke or fork is required to operate this head which is arranged with an adjustable stop on each side of its travel.

For drill press work, the shanks of the style AA head can be modified to provide the proper standard tapers to fit the spindle of the drill press. The diameter of the thread cut is adjusted by means of a micrometer adjusting screw on the front face of the tool.

Duplex enclosed flood lubricated pump

THE enclosed type of self-lubricating power pump recently placed on the market by the Gardner Governor Company, Quincy, Ill., is a general service pump for boiler feeding, water circulation, pressure boosting, water supply or any other service where a pump is required. With an installation arranged so that the pump can be operated by a float switch or remote control, the pump can be started by merely turning a switch which eliminates most of the attention required by an attendant.



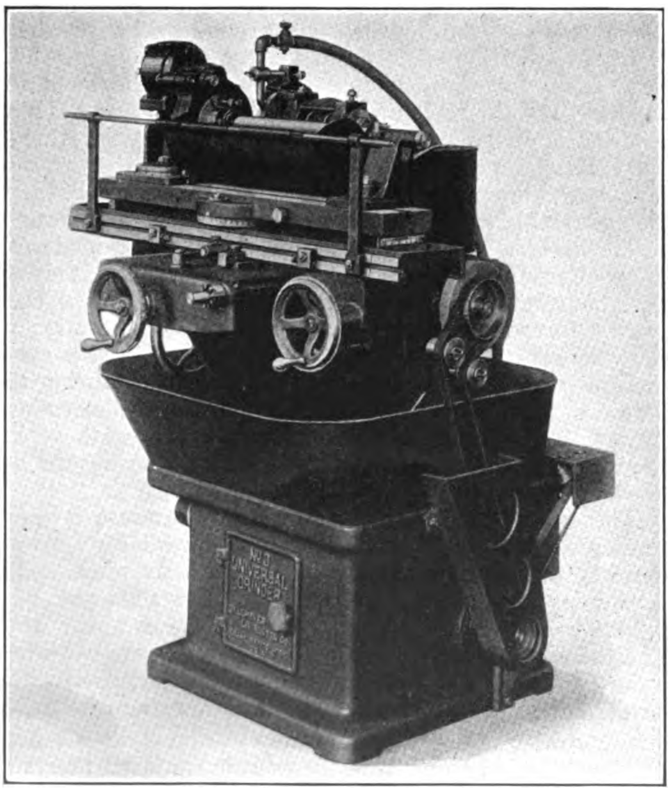
Packed piston type pump with the motor mounted on top of of the frame

All the running parts of the pump are totally enclosed in the crank case which acts as an oil reservoir for the flood lubricating system. Grease cups, oil cups and sight feed oilers have been entirely discarded. The lubricating system is automatic and positive. The main driving gear, partially submerged in oil, delivers the oil through channels to the main and pinion shaft bearings, crank and crosshead pin bearings and crosshead guides. All the working parts are flooded with oil, which insures long life and continued smooth operation.

The type of valve used is determined by the kind of liquid pumped. Medium rubber valves are recommended for cold water service and hard rubber or brass valves for hot water. The brass valves in packed pistons and outside packed pumps are light weight disc valves with a curved web. The oil line pumps have brass wing guided valves seated on a taper.

Universal cutter and tool grinder

ON page 1588 of the June 14, 1924, daily edition of the Railway Age will be found a description of a universal tool room grinder manufactured by the Gallmeyer & Livingston Company, Grand Rapids, Mich. Since the publication of this description improvements have been made on the machine, principally in the addition of a motor driven, wet grinding attachment.



Motor driven grinder provided with a power feed and a wet grinding attachment

The machine is made in two sizes, either of which can be operated from the front or the rear. Transverse, vertical and longitudinal movements can be made from either position. Furthermore, from the front of the machine a choice is offered for longitudinal movement between a rapid action lever handle and a slower handwheel movement. For both vertical and cross feed movement the hand wheels are graduated in thousandths, the graduations being coarse enough to be easily split, if necessary. Pointers with movable set collars, make the reading easy. In service, the machine can be made to perform practically every operation in either of two ways: by either having the spindle head locked in position on the central column and swivelling the sleeve knee, etc., around it, or by leaving the sleeve locked in a fixed position and swivelling the head to the desired position. Individual preference, on the part of the operator, can be the guide in most cases, but in some instances the difference in direction of artificial and natural daylight makes it desirable to take advantage of the opportunity offered for swivelling the knee saddle into the best lighted position and then swivelling the head to the proper position for effecting the grinding job in hand. One setting can be used for daylight and another for artificial illumination and each of them give the desired convenience.

The wet grinding attachment may be added to the machine or not, as preferred. Where cylindrical grinding is to be done, wet grinding is essential and it is desirable for many other jobs. The accompanying illustration shows the machine arranged for cylindrical grinding with the splash guards in place. A copious flow of water is provided from a centrifugal pump with no stuffing boxes or other parts to wear. The pump is driven from the motor shaft in the base on motor driven units, or by a belt from the countershaft on belt driven machines. Water is supplied in large volume but without sufficient pressure to cause splashing. The guards keep the water in the

machine and return it to the tank with its settling chamber ready for further use. The tank can be quickly removed for cleaning.

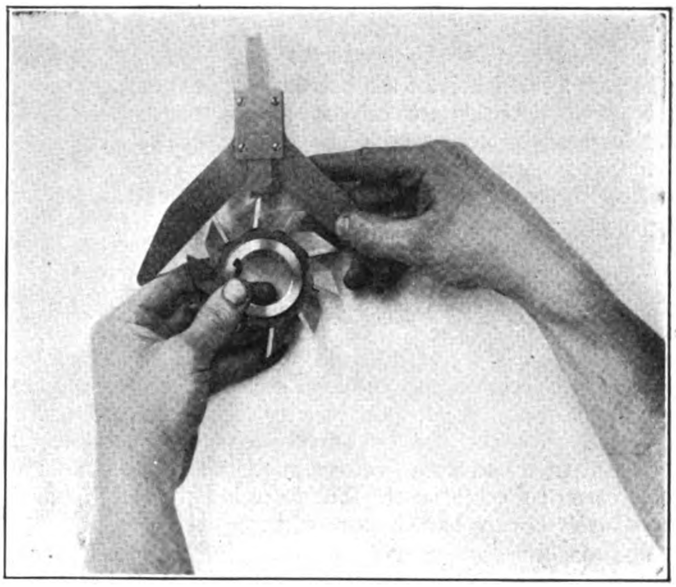
Some of the dimensions of the machine are as follows: Size of table, 5½ in. by 42 in.; longitudinal travel, 18 in.; transverse movement, 10 in.; vertical movement, 10¾ in.; maximum swing, 10½ in. by 26 in.; and maximum distance from center line of the spindle to the table, 10½ in.

Convenient tools for the tool room

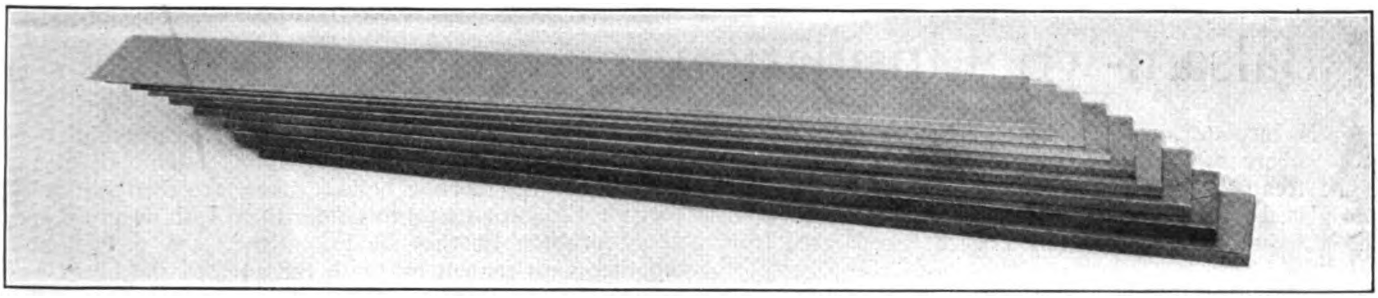
A CUTTER clearance gage and ground flat stock are recent additions made by the Brown & Sharpe Manufacturing Company, Providence, R. I., to its list of hand tools. The clearance gage is a simple device designed for the purpose of aiding in grinding the correct angle of clearance on milling cutters. It may be used for right and left hand cutters and for end mills of all styles. The vee-shape body locates the cutter and holds the gage blade in correct relation to the center line of the cutter. All contact surfaces are hardened and ground. Two gage blades are furnished, each of which is stamped at each end with the diameter of the cutters for which it is intended to be used.

The gage will measure all style cutters from ½ in. up to 8 in. in diameter, and of any width. Its use is very simple. The inside surfaces of the vee arc are brought in contact with the cutter as shown in one of the illustrations, and then the gage blade is dropped on the tooth to be gaged. The cutter is revolved sufficiently to bring the face of the tooth in contact with the gage blade. The angle of clearance in the tooth should correspond with the angle of the gage thus accurately determining whether the cutter teeth are properly cut or not.

The railroad toolroom is often required to make templates, gages and small tools from flat stock. The ground flat stock shown in the illustration is well adapted to this class of work. This stock is now available in three new thicknesses, 3/64 in.; 5/16 in.; and ⅜ in., and in six new square sizes varying from ¼ in. to 1 in. square. New widths can also be obtained from ½ in. to 6 in. in some thicknesses. This stock is made from tool steel, cut and annealed, then accurately ground to thickness. Each piece of stock is 18 in. long.



Method of using the Brown & Sharpe cutter clearance gage



Ground flat stock for use in the tool room

Heavy duty vertical boring and drilling machines

THREE sizes of heavy duty vertical boring, drilling and milling machines have recently been placed on the market by Baker Brothers, Inc., Toledo, Ohio. Size No. 525, which is shown in the accompanying illustration, is the largest of the three. In the next size, the machine has a 24-in. gap and a swing of 48-in. which makes it possible for the machine to handle a wide range of miscellaneous work for facing, tapping and drilling operations.

The machines are designed for heavy and rapid boring, drilling, facing and tapping and have ample capacity to drive high speed drills of their rated sizes to their limit of efficiency in steel. They can be used for boring and enlarging in steel and cast iron for which operations they are especially designed. Instantaneous change from drilling to reaming feed in the correct ratio is also provided.

Eight speed changes are provided which may be instantly made without stopping the machine. The drive is through a train of hardened alloy steel gears, running on high grade annular ball bearings, all enclosed in an oil-tight box. A minimum number of gears are running in mesh at any time. Twelve drilling and twelve reaming feeds are provided. The feed rack is of alloy steel as is the feed pinion which meshes with it and which is cut directly on the shaft. A large bronze worm gear with provision for securing uniform wear and a safety shear

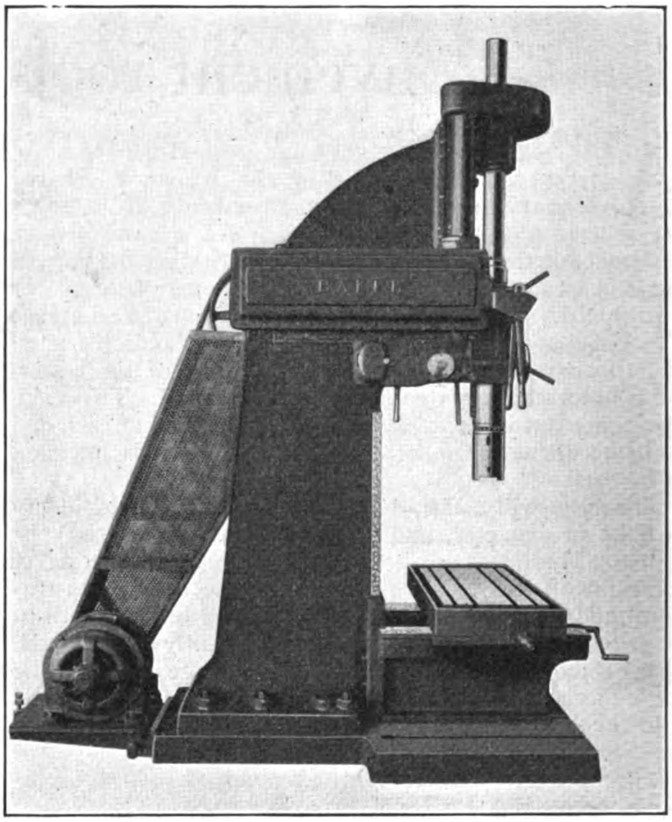
pin to protect the feeding mechanism from abuse are provided.

The spindle is of forged steel and is fitted with special chrome ball-thrust bearings. The spindle nose is bored for No. 6 Morse taper. It is slotted across the end for driving heavy boring and facing heads, fitted with a cross drift for holding these heavy tools securely and, in addition, has a hollow set screw to prevent the light tools from dropping out.

These machines have an automatic depth stop with fine adjustments. A special pair of feed change gears which may be applied at any time permits facing to an exact depth. It only requires a few seconds to apply these gears. Capstan handles are provided for rapid traverse; in addition, hand worm feed is provided.

The table, which is of the box-knee type, heavily braced and provided with unusually ample oil grooves, is raised and lowered by means of a telescoping screw. The construction is such that a 4-in. hole may be bored for supporting a boring bar of that diameter, the table being reinforced for this purpose. The bottom of the knee has the projecting edges planed parallel, permitting the use of parallel bars to take the thrust for extremely heavy work. The compound table is of the box-knee or heavy milling machine type. The adjustments are made by means of cut screws with a lead of one inch to the revolution. The operator can handle both movements simultaneously without changing his position. Furthermore, the screw adjustments may be quickly made. An ample oil pocket at each end with grooves at the sides and drainage takes care of the lubricant. The knee is bored and bushed for a lower boring bar support when desired.

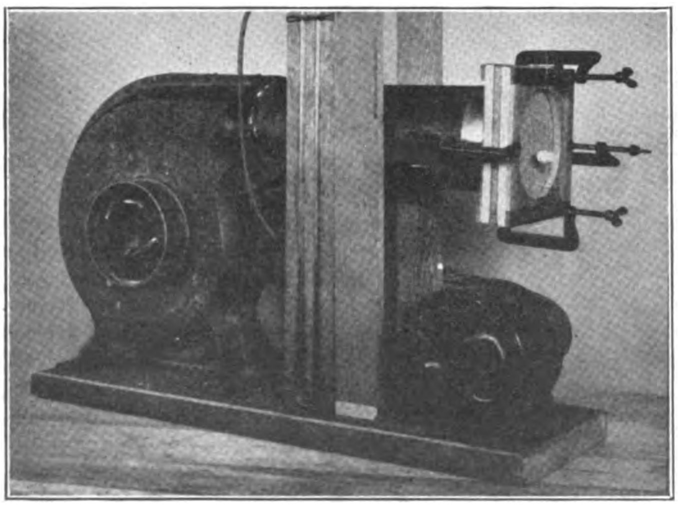
The machine can be arranged for driving direct from a motor and when so arranged, the sub-base is extended back and the motor is belted direct by means of a belt up to the machine driving pulley. The machine is started and stopped by means of shifting belt on tight and loose pulleys which run on ball bearings, a spring device holding the belt securely on or off. In the off position a brake is applied in such a manner as quickly to stop the spindle and hold it effectually stopped. A tapping reverse can be furnished if desired.



Baker 5-in. capacity vertical boring and drilling machine arranged for motor drive and equipped with a compound table

Balsam-wool insulation for refrigerator cars

An insulator, called Balsam-Wool, made from the fibers of coniferous northern woods, chemically treated to withstand refrigerator car service has been placed on the market by the Wood Conversion Company, Cloquet, Minn. The fibers are first separated from one another by chemical and mechanical means similar to those used in pulp making. The individual fibers, which are fine, hairlike hollow tubes, are then saturated with chemicals that tend to render them both fireproof and decay proof. In this condition, they are next bound together with cement but with the axes of the fibers extending in all three cubical dimensions and not parallel to each other as in wood. The result is a resilient blanket of fibers which weighs only 5 lb. per cu. ft., or less than one-half the weight of cork. It contains countless still air cells, over 94 per cent of the volume being still air.



Testing equipment designed to determine the porosity of insulators

To increase the mechanical strength of the fibrous blanket, it is covered on both sides with a layer of creped waterproof Kraft paper which is cemented to the blanket of fibers by a high melting point asphalt. This covering layer is impervious to the passage of both water and air.

Tested for thermal conductivity, the average heat flow in 24 hours through Balsam-Wool is 6.1 B.t.u. per sq. ft. per in. thickness per deg. F., some samples testing as low as 5.7. The flexible texture of this product makes it elastic, and this elastic principle is further carried out through the use of the creped Kraft paper liner which it is said can be stretched 25 per cent or more without tearing. This is a greater stretch than occurs when the top of a refrigerator car weaves 8 in. out of line.

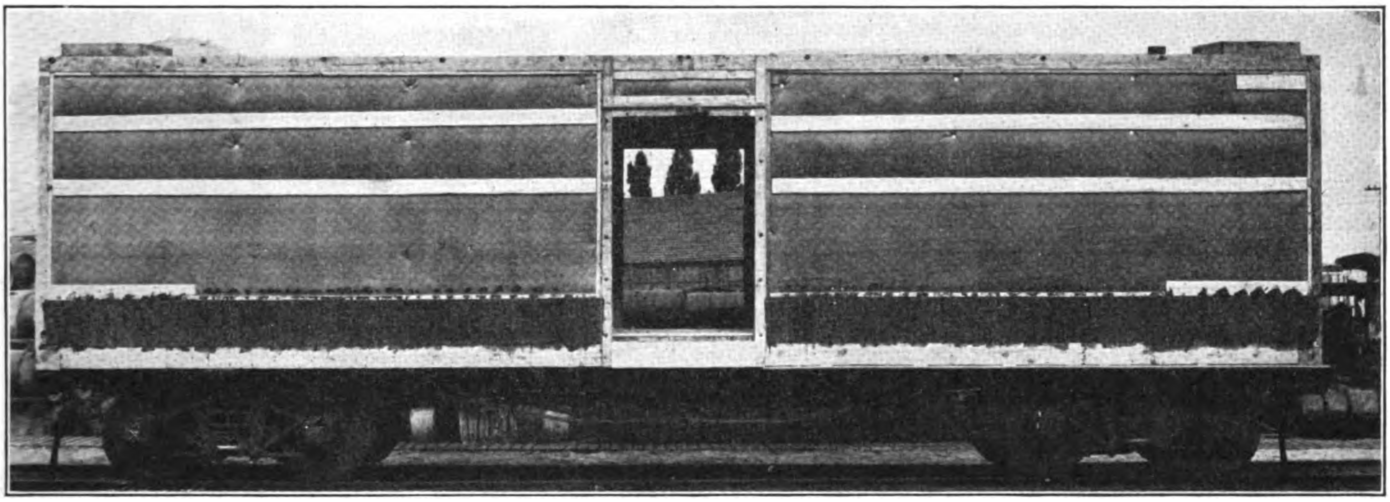
Some interesting tests of Balsam-Wool were conducted by Howard F. Weiss, research engineer of the C. F.

Burgess Laboratories, Madison, Wis., as follows: To test the resistance of the material to mechanical wear and tear, a machine was constructed on which was mounted a section of a refrigerator car side frame 8 ft. high and 4 ft. wide. To this section the insulators under test were then nailed. The machine was started and it thrust the top of the frame 8 in. out of plumb with the bottom. The whole frame at the same time being lifted and dropped 3/16 of an inch rapidly enough to give it a vibrating motion. The object sought was to duplicate as closely as possible what happens to an insulator fastened to a refrigerator car which is in bad condition and rolling over a rough track. After being subjected to many repeated thrusts and vibrations, the Balsam-Wool did not tear or shake down.

To test for porosity, an air pressure equivalent to an air velocity 40 miles an hour was maintained against one side of the insulator as illustrated, a manometer being used to indicate the pressure. The distance the cotton ball was blown from the perpendicular was used as a measure of the permeability of the insulator to air and in the case of Balsam-Wool there was no perceptible movement of the cotton ball. When inoculated with molds and fungus and placed in a warm, damp, atmosphere, no growth occurred.

The asphalt-coated liners are resistant to the passage of moisture so that the interior blanket of fibers is protected when exposed for an appreciable time to a high humidity. The tests showed that Balsam-Wool will absorb about 30 per cent moisture, or over twice as much as that of cork when subjected for a long time to a humidity of 90 per cent or more. However, at 30 per cent moisture, Balsam-Wool is said to contain less moisture per square foot than cork at 15 or 10 per cent moisture because of the former's extremely low density. Therefore, its thermal resistance, even when subjected to high and to prolonged humidity, is not seriously impaired by this condition.

The product comes in large sheets that are light in weight and can be easily cut and nailed. It is said to be possible to save 2,000 lb. or more of dead weight in the construction of a refrigerator car by the use of this insulation. About 20 cars have been equipped to date.

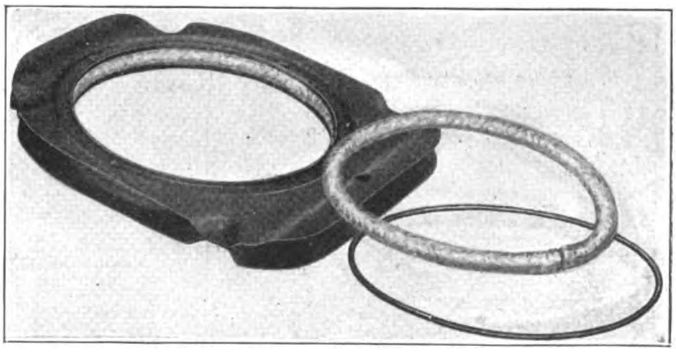


How Balsam-Wool insulation is applied to a refrigerator car

Journal box dust guard

A JOURNAL box dust guard manufactured in all sizes for freight and passenger equipment to conform to the American Railway Association standards has recently been placed on the market by the Union Asbestos & Rubber Company, Chicago. The purpose of the design is to maintain an oil-retaining and dust-proof joint around the axle and the side of the dust guard chamber.

Its construction differs somewhat from the usual design of dust guards. The two sides of the guard are pressed from steel sheets and securely spot welded together at four points. One side plate of the guard is so formed as to act as a spring and forces the opposite side tightly against the oil and packing retaining wall of the journal box. This arrangement provides a dust-proof joint between the dust guard and the side of the dust guard chamber and makes it self-supporting in the box, eliminating continuous and uneven wear at the top of the bore of the guard, as is the case where it rides on the axle. A special asbestos packing ring, inserted in the groove formed in the guard, is automatically held in close contact with the axle at all points on its circumference by means of a circular steel spring.



Dust guard pressed from steel sheets—An asbestos packing ring is used

Compact high speed electric hoist

A COMPACT, high speed electric hoist has been added to its line of products by the Roeper Crane and Hoist Works, Reading, Pa. The worm is placed above the gear. This is the reverse of the usual worm gear drive on most tools and is said to remove the cause of considerable wear. The worm shaft is equipped with a ball end thrust bearing.

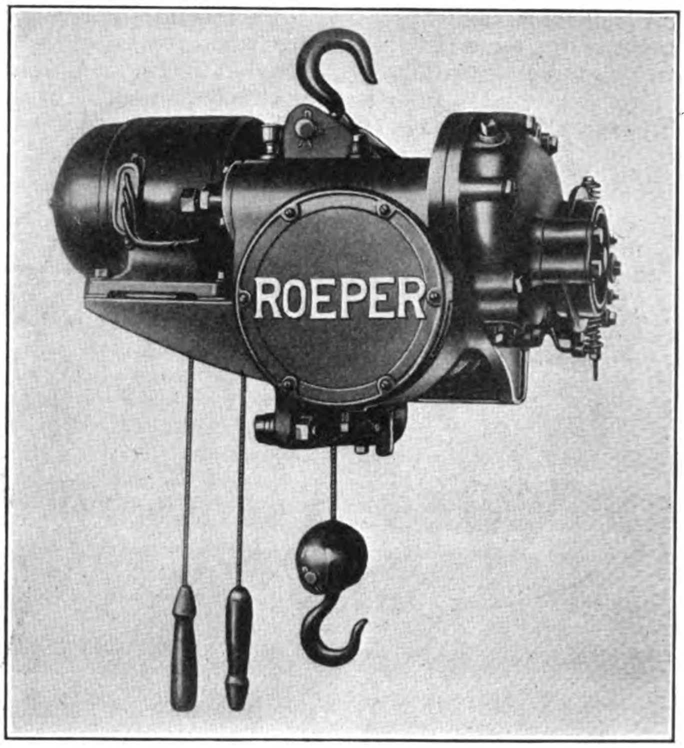
The motor is mounted on its feet directly upon an extension of the hoist frame. The main frame of the hoist is a one-piece casting that contains all the bearings so that shafts and moving parts, once assembled, cannot get out of alinement.

Steel suspension plates, reaching from the drum shaft to the overhead suspension members, relieve all tension on the castings and provide a means for a hook, link, clevice or any special form of suspension. An automatic stop of the trip lever type, positive in its action, affords protection in extreme lifting and lowering. This stop can be adjusted for any distance of hook travel.

The need of a load brake is removed by the worm drive. The motor is equipped with a mechanically operated jaw brake acting in series with the controller, which brings the motor to a quick stop, preventing drifting of the load when the power is cut off.

The controllers are of the single-speed drum type of standard design. For this control, the motor is equipped with an electric magnetic brake and an adjustable upper and lower electric limit switch.

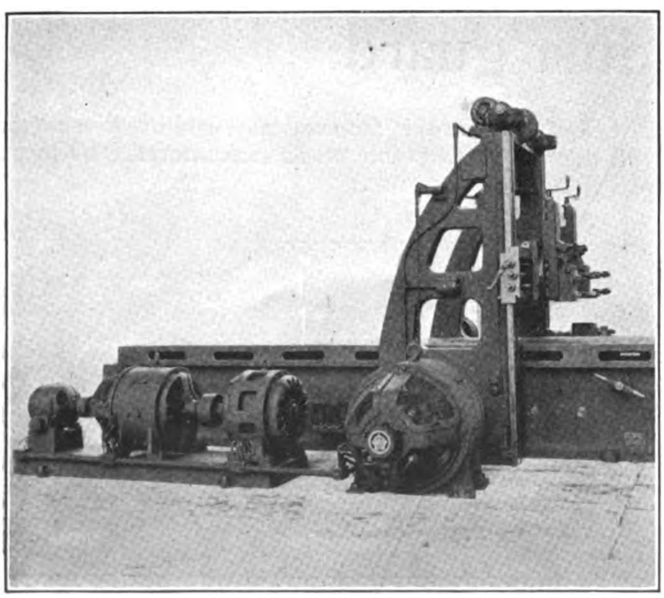
While the illustration shows a hoist for hook suspension, it can also be furnished with either plain or geared I-beam trolleys with roller bearing wheels. Provision is also made for direct connection of the hoist to any standard trolley for a flat rail or a special track. The hoist can be furnished in 500, 1,000 and 2,000 lb. capacities with a single strand of hoisting cable.



Roeper Type R electric hoist with the worm gear placed above the gear

Alternating current motor drive for planers

IT is now generally acknowledged that driving a planer by a direct current adjustable speed motor connected directly to the machine is superior to any type of drive through belts or clutches. This is because of the higher cutting and return speeds possible, the ease with which any cutting or return speed may be obtained, accuracy of reversal and lower maintenance cost of the reversing motor drive.



Rear view of a planer showing the reversing driving motor and motor generator set with separate excitor

The advantages of the reversing motor drive for planers have, until recently, been confined to plants having a supply of direct current. It is now possible for the plant which has only alternating current available to obtain a reversing motor drive. The equipment by which this is accomplished comprises a direct current adjustable speed reversing motor connected directly to the planer, current for which is furnished by a generator driven by a motor which uses the alternating current from the main line. The connections between the planer motor and the generator are never broken when in use, therefore a controller with a multiplicity of relays and contactors for carrying the large armature current is not required. The entire control of the planer motor for direction and speed is obtained by manipulation of the small field current of the generator. Reversal of the field current of the generator changes the direction of the generated current and hence reverses the direction of rotation of the planer motor. The reversal of the generator field is effected by an oscillating drum switch operated by dogs on the table, the contacts being closed and opened under oil in the enclosing case.

Changes in speed of the planer motor are obtained by varying the field current of the generator; reducing the field current lowers the voltage of the generated current

and hence lowers the speed of the planer motor; increasing the field current raises the voltage and the speed of the planer motor is increased. The changes in field current are obtained through separate rheostats adjusted by hand for the cutting and return strokes; any cutting speed may, therefore, be used with any return speed within the range of the equipment. The generator and driving motor are mounted on one base and may be placed in any convenient location as the only connection between the generator and the planer driving motor is by wire. With this equipment, cutting speeds from 25 to 60 ft. per min. and return speeds as high as 160 ft. per min. can be obtained. Cutting speeds below 25 ft. can be obtained if necessary.

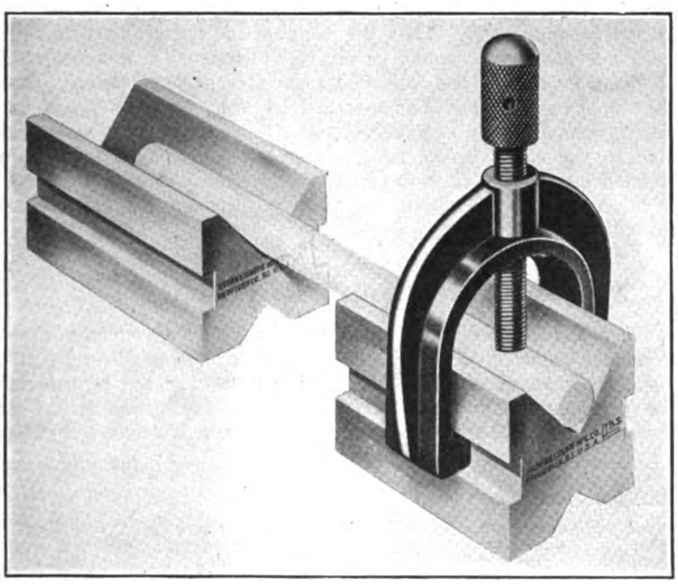
Failure of line voltage is liable to occur at any time from various causes. If the line voltage fails, the generator will continue to run for a short time because of its momentum, but since the control is effected through the generator field circuit, the planer will be reversed as usual until the whole system gradually comes to rest. Stops at each end of the table prevent accidents caused by the operator failing to fasten the reversing dogs.

The equipment includes a safety pendent switch suspended from a swivel on the arch or crosstie of the planer by a flexible cable which enables the operator to keep the switch close at hand when working. The entire control of the table motion, starting, stopping, reversing or jogging by very small fractions of an inch, is obtained by the single knob on this switch without requiring the operation of any other devices. The machine when running may be stopped instantly by pushing the knob upward.

This equipment has been placed on the market by the Niles-Bement-Pond Company, New York.

A pair of useful V-blocks and clamp

The pair of V-blocks and clamp shown in the illustration are particularly useful for holding circular pieces to be drilled, milled or ground. They hold the piece



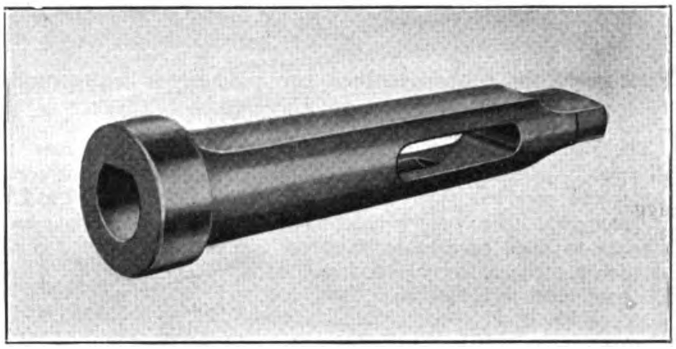
Method of using V-blocks and clamp

firmly and prevent it from turning or slipping while the work is being done.

The blocks are made of cast iron and are intended for general machinist's use. They are carefully finished and the grooves on the sides of the blocks are accurate. Each block is 2 in. long by $1\frac{1}{2}$ in. square and will hold work up to $1\frac{1}{2}$ in. in diameter. They are made by the Brown & Sharpe Manufacturing Company, Providence, R. I.

Improved sleeve for holding drills and reamers

When drilling or reaming holes it is often necessary to use two or more sleeves when the tool used has a small shank. When the Lovejoy Tool Works, Chicago, redesigned its original drill sleeve they had this point in mind. The new sleeve is flattened on the

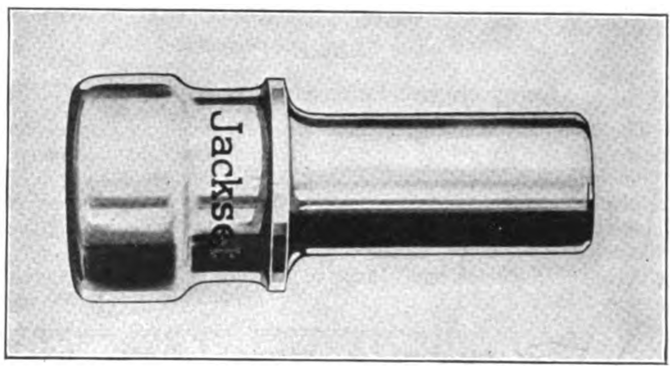


Drill sleeve designed for nesting

outside so that the sleeves can be nested. It also has a strong re-enforcement at the lower end of the sleeve which is claimed to make it much stronger than the original design. The inside and outside dimensions are practically the same as the standard Morse drill sleeve.

Triple service alloy steel rivet sets

The life of a rivet set is determined by the number of rivets it will drive before it breaks. The Ingersoll-Rand Company, New York, has recently placed on the market a rivet set for pneumatic hammers which is said to



Ingersoll-Rand alloy steel rivet set

have shown a great increase in rivets driven per set over other types previously manufactured by this company. It is made of alloy steel which will stand a great degree of heat from hot rivets without the temper becoming drawn. It is specially forged and then heat treated by a new process.

General News

Damage estimated at $500,000 was caused by a fire at the shops of the Canadian National at Bridgewater, Nova Scotia, recently. Most of the buildings, together with eight locomotives, a number of freight cars and a large quantity of stores were destroyed. The buildings consumed included the roundhouse, machine shop, car shop, boiler shop, master mechanic's office and some smaller buildings. Some damage, too, was done to the station on the opposite side of the tracks. Seven of the eight locomotives destroyed were serviceable, and the eighth was undergoing repairs.

Pennsylvania places orders for passenger equipment to cost $6,000,000

The Pennsylvania has placed orders for 357 passenger cars of all steel construction, to be delivered as soon as equipment companies can complete their construction. The orders call for 222 baggage cars, 105 passenger coaches, 15 combination passenger and baggage cars, 10 combination baggage and mail cars and 5 combination passenger, baggage and mail cars. The estimated cost of this equipment is $6,000,000.

Locomotive inspection, first six months of 1925

During the first six months of 1925, 40,321 locomotives were inspected by the Bureau of Locomotive Inspection of the Interstate Commerce Commission, of which 18,151 were found defective and 1,910 were ordered out of service, according to the Commission's monthly report to the President on the condition of railroad equipment. During June 7,381 locomotives were inspected, of which 3,044 were found defective and 292 were ordered out of service. The Bureau of Safety during the same month inspected 95,215 freight cars, of which 2,709 were found defective, and 2,011 fuel oil showed an increase. The average cost of fuel for road locomotives in freight and passenger train service (charged to operating expenses) for Class I steam railways in April was $2.79 a ton, as compared with $3.19 last April and $2.81 for four months of this year. There was also a reduction in the number of tons used, and the total cost for the month was $20,532,551. The average cost of fuel oil was 3.29 cents per gallon, as compared with 2.80 cents last April and 3.11 cents for four months. The total passenger cars, of which 23 were found defective. During the month 16 cases, involving 32 violations of the safety appliance acts, were transmitted to various United States attorneys for prosecution.

Long engine runs on the Southern

The Southern Railway is now running passenger locomotives long distances on a half dozen of its main lines, as follows:

Between Washington and Atlanta, 637 miles, two engines instead of four, changes being made at Spencer, N. C., the changes formerly made at Monroe, Va., and Greenville, S. C., having been eliminated.

Between Cincinnati and Jacksonville, 840 miles, three engines are used instead of six, changes being made only at Chattanooga and Macon. Formerly engines were also changed at Somerset, Atlanta and Valdosta.

Between Cincinnati and New Orleans, 836 miles, three engines are used instead of five, changes being made only at Chattanooga and Meridian. Engines are also being run through without change between Bristol, Va., and Chattanooga, Tenn., 242 miles; Chattanooga and Memphis, 314 miles; Atlanta, Ga., and Columbus, Miss., 290 miles; Louisville, Ky., and St. Louis, Mo., 274 miles; and Rome, Ga., and Meridian, Miss., 300 miles.

I. C. C. requested to provide an accounting system which will show true car repair costs

On July 14 a communication was addressed to the members of the Interstate Commerce Commission by seventeen representative members of the freight car repair industry, criticising the decision of the Commission relative to the contracting of equipment repairs by the railroads which it rendered on the basis of an investigation instituted early in 1921. It was claimed that the report of the inquiry made in 1921 did not present all of the essential information pertaining to car repair contracts, and that full hearings had not been conducted, although the report inferred that such had been the case. Furthermore, the system of accounting used by the railroads, which was approved by the Commission, did not show the actual car repair costs as overhead costs were not included.

The representatives of the freight car industry presented twelve factors which they considered to be sufficiently important to merit consideration by the Commission, some of which are as follows:

That the main business of railroad companies is transportation, which is a special occupation requiring special training, and is, in its fundamentals, as foreign to manufacturing as the latter is foreign to transportation. Railroad shops have no spur of competition but have a substantial monopoly of a railroad's work. Railroad accounts cannot show, and do not show, proper manufacturing costs, and are not a useful factor in controlling manufacturing costs, for if existing railroad accounts had contained proper and informative manufacturing data, it would not have been necessary for the Commission to make a special study of the cost for the investigation in 1921. That the Commission's decision that railroad overhead costs could be entirely disregarded was contrary to common reason and scientific principles of accounting. That the duplication of facilities afforded by both a railroad and car repair industry is an economic waste. That no conclusion applicable to the car industry as a whole can be justly drawn from isolated instances. That no proper comparison can be made unless it takes into consideration the relative speed of the delivery of the work performed.

Wage statistics for April

Class I railroads reported to the Interstate Commerce Commission a total of 1,745,643 employees as of the middle of April, 1925, an increase of 23,368, or 1.4 per cent over the returns for the previous month. The maintenance of way group shows an increase of 40,710 employees, but this increase is offset somewhat

Freight Cars Installed and Retired

Month 1925	Installed during month	Aggregate capacity tons	Retired during month	Aggregate capacity tons	Owned at end of month	Aggregate capacity tons	Building in R. R. shops
January	11,768	551,263	7,867	326,812	2,341,109	103,812,974	5,285
February	15,024	721,867	9,453	365,111	2,346,687	104,169,525	4,878

Figures as to installations and retirements prepared by Car Service Division A. R. A. Figures cover only those roads reporting to the Car Service Division. They include equipment received from builders and railroad shops. Figures of installations and retirements alike include also equipment rebuilt to an extent sufficiently so that under the accounting rules it must be retired and entered in the equipment statement as new equipment.

by decreases in the maintenance of equipment and transportation groups. Notwithstanding the net increase in the number of employees, the total compensation, $234,808,094, shows a decrease of $3,368,830, or 1.4 per cent, which resulted principally from a decrease in the number of hours worked per employee.

Compared with the returns for the same month last year, the employment in April, 1925, shows a decrease of 2.3 per cent and the total compensation a decrease of 0.9 per cent. The average straight time earnings per hour for all employees reported on an hourly basis increased from 57.4 cents per hour in April, 1924, to 58.2 cents in April, 1925.

Foreign railway news

Motive power and rolling stock on the Italian State Railways during 1924 was improved by the addition of 40 steam and 147 electric locomotives, six passenger cars, one baggage car, and 417 freight vehicles for the standard gage lines. During the year, 116 steam locomotives were withdrawn from service, and 707 passenger cars, 202 baggage and mail cars, and 4,463 freight cars were retired.

Sixty locomotives and 20 tenders for the Czechoslovak Railways will be purchased shortly, according to an announcement by the Ministry of Railways. The Ministry of Finance has been requested to provide the necessary funds, and the appropriation is expected to be made available this month. It is understood, however, that only Czechoslovak manufacturers will be invited to submit bids.

The Polish government will order for its railways rolling stock to cost $7,000,000, including 4 locomotives, 3,000 freight cars and 100 passenger cars and $4,200,000 worth of rails, switches and signal apparatus. The railways will also spend $7,200,000 on improvements to car shops, for which considerable new material will be purchased.

The liberal investment of the German railways in new equipment during the inflation period is now being reflected in abnormally low orders for locomotives and other rolling stock by the railway board established under the Dawes plan, according to Commercial Attaché Herring, at Berlin. According to most observers the German railways at the end of 1923 were in excellent condition, apart from the abnormal deterioration under the Franco-Belgian Régie during the Ruhr occupation. There is, therefore, considerable uneasiness now in German rolling-stock plants because of the tendency of the railway administration to limit new orders drastically. Only 80 locomotives are to be ordered during the current year, and there will be a corresponding reduction in contracts for spare parts and other equipment, except material for track building. The situation is not as serious as it might be, however, because such large companies as the Allgemeine Elektricitaets-Gesellschaft and the Borsig and Krupp works, which manufacture a large variety of products, are able to divert some of the labor employed in rolling-stock shops to other branches of their plants and otherwise adapt themselves to the situation. The fact remains, however, that even with reduced production, pressure on export markets will be greater, and there will doubtless be a more pronounced tendency to underbid American and foreign manufacturers—dumping German stock at sacrifice prices and compensating by price increases in lines where the domestic or foreign market, or both, is better able to absorb German goods.

Woman invents sleeping car of unique design

Mrs. Agnes R. Rossman, Scotch Plains, N. J., has recently designed and received patents on a sleeping car which is a real innovation in sleeping car architecture. The lower berths are so designed to insure perfect privacy. The berth, when made up, is enclosed by rolling steel curtains which are locked on the inside by the occupant. A private dressing room with a toilet and wash basin, is provided for each lower berth. They are arranged two rooms together with a connecting door. The dressing room doors leading to the aisle are provided with a shoe bin with a glass in it so that the porter can see whether or not they contain shoes. The porter can open the bin from the outside by a master key. These doors also contain an exhaust blower fan which is controlled by a two-stay switch. The fans can be used for blowing the air from the dressing room and lower berth or for drawing fresh air into these rooms. This arrangement maintains perfect ventilation. Each car is provided with two shower baths, one with each private dressing room of the berths at each end of the car. The lower berths are so designed that if the passenger is tall, the berth can be extended six or eight inches, thus providing ample space for the occupant.

The upper berths are easily accessible by means of a permanent folding stairway which the occupant can place in position without calling a porter. Along the edge of each upper berth runs a safety rail which protects the passenger from falling out. These berths have tight fitting sliding curtains independent of the lower berth which may be fastened on the inside, insuring privacy. The upper berths are provided with a luggage closet over the private dressing rooms of the lower berths, accessible through two doors, one opening into the upper berth and the other to the aisle. This closet provides ample space for luggage, facilities for hanging up clothing as well as trays, racks, etc., for toilet articles, a rack for a thermos bottle, a mirror for dressing and space for shoes.

In the day time this car has practically the same appearance as the present day Pullman. The occupants of the private berths have the advantage of seeing out both sides of the car, which is not obtainable in a compartment car.

Meetings and Conventions

Tool Foremen's Association to meet in Chicago

The American Railway Tool Foremen's Association will hold its thirteenth annual convention at Hotel Sherman, Chicago, on September 2, 3 and 4. H. T. Bentley, general superintendent of motive power of the Chicago & North Western, will deliver the opening address. G. T. Martin, assistant to general superintendent of motive power of the Chicago, Milwaukee & St. Paul, will speak on "The Tool Foreman's Responsibilities," and E. L. Woodward, western mechanical editor of the Railway Age, will present a paper on "The Importance of the Tool Room." Committee reports will deal with the following subjects: Standardization of tools in the locomotive and car shops; grinding in the railroad shops; jigs and devices for the locomotive and car shops; forging machine dies; machine tool equipment for the tool room, and economies possible by standardized small tools. An exhibit of machine and hand tools in connection with the convention will be displayed by the Supply Association of the American Railway Tool Foremen's Association.

New York Railroad Club outing

The New York Railroad Club held its second annual outing, or mid-summer festival, at the New York Athletic Club, Travers Island, and at the Winged Foot Golf Club, Mamaroneck, N. Y., on Thursday, July 9. Over 200 golfers went to the golf club early in the morning. A special train left New York for Travers Island at noon. The Long Island Railroad Band played en route and headed the procession in the march from the station at Pelham Manor to Travers Island. A buffet luncheon and dinner were served at the clubhouse and the party returned to New York on a special train late in the evening.

Among the various forms of relaxation which were a part of the outing were a number of competitive sports in which prizes were awarded. These included a golf tournament at the Winged Foot Golf Club and a tennis tournament and track meet at Travers Island in the afternoon. A variety of prizes was offered in the golf tournament covering low gross, low net, "kicker's" handicap, and others, the winners of prizes being as follows: D. D. Cooke, American Locomotive Company; C. E. Bryant, Johns-Manville, Inc.; G. H. Weiller, American Locomotive Company; H. M. Behre, Surety Engineering Company; L. O. Smith, Columbia Machinery Works; C. G. Melvin, Galena Signal Oil Company; W. J. Fripp, general manager, New York Central; C. C. Hubbell, purchasing agent, Delaware, Lackawanna & Western; C. L. Bardo, formerly general manager, New York, New Haven & Hartford; Frank Hedley, president, Interborough Rapid Transit, and A. N. Dugan, Bronze Metal Company.

The results of the track meet were as follows: 100-yd. dash won by E. Dunbar, Pennsylvania System, 10⅗ sec.; 220-yd. dash won by S. Marion, Erie Railroad, 24⅖ sec.; first 440-yd. race won by H. Higgins, Safety Car Heating & Lighting Company, 54 sec.; second 440-yd. race won by J. F. Mitchell, Interborough

Rapid Transit, 54 sec.; 880-yd. run won by G. C. Gault, Safety Car Heating & Lighting Company, 2 min. 5⅗ sec.; one-mile relay race for company teams won by the Safety Car Heating & Lighting Company, 3 min. 30 sec., with the Erie, second, and the Interborough team, third.

In the tennis tournament, the singles were won by R. P. Spooner, American Abrasive Metals Company, with Harry Doyle, runner-up. The doubles tournament was won by Harry Doyle and C. C. Willetts. Other special features were a soft ball baseball game between the railroad men and the railway supply representatives, swimming and quoits. Scott Donahue was chairman of the General Committee. J. S. Doyle, superintendent of equipment, Interborough Rapid Transit Company, was director of sports and entertainment.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs.

AIR-BRAKE ASSOCIATION.—F. M Nellis, Room 3014, 165 Broadway, New York City.

AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

AMERICAN RAILWAY ASSOCIATION, DIVISION V.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago.

DIVISION V.—EQUIPMENT PAINTING SECTION.—V. R. Hawthorne, Chicago. Next meeting September 15, 16 and 17, 1925, at St. Paul Hotel, St. Paul, Minn.

DIVISION VI.—PURCHASES AND STORES.—W. J. Farrell, 30 Vesey St., New York.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—G. G. Macina, 11402 Calumet Ave., Chicago. Annual convention September 2-4, Hotel Sherman, Chicago.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Railroad Division. A. F. Steubing, Bradford Corp., 25 West Forty-third Street, New York.

AMERICAN SOCIETY FOR STEEL TREATING.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio. Annual convention week of September 14, 1925, Cleveland, Ohio.

AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago, Ill. Annual meeting October 27 to 30, inclusive, Hotel Sherman, Chicago.

CANADIAN RAILWAY CLUB.—C. R Crook, 129 Charron St., Montreal, Que. Regular meetings second Tuesday in each month, except June, July and August, at Windsor Hotel, Montreal, Que.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 N. Pine Ave., Chicago, Ill. Meeting second Monday in month, except June, July and August, Great Northern Hotel, Chicago, Ill.

CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—R. E. Giger, 721 North 23rd street, E. St. Louis, Ill. Meetings, first Tuesday in month, except June, July and August, at the American Hotel Annex, St. Louis.

CAR FOREMEN'S CLUB OF LOS ANGELES.—J. W. Krause, 514 East Eighth street, Los Angeles, Cal. Meeting second Friday of each month in the Pacific Electric Club Building.

CENTRAL RAILWAY CLUB.—H. D. Vought, 26 Cortlandt Street, New York, N. Y. Regular meetings second Thursday each month, Hotel Statler, Buffalo, N. Y.

CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—A. S. Sternberg, Belt Railway, Clearing Station, Chicago. Annual convention Hotel Sherman, Chicago, September 22-24.

CINCINNATI RAILWAY CLUB.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meetings second Tuesday, February, May, September and November.

CLEVELAND STEAM RAILWAY CLUB.—F. L. Frericks, 14416 Adler Ave., Cleveland, Ohio. Meeting first Monday each month except July, August and September, at Hotel Cleveland, Public Square, Cleveland.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—W. J. Mayer, Michigan Central, 2347 Clark Ave., Detroit, Mich. Next convention, Hotel Winton, Cleveland, Ohio, August 18, 19 and 20.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. B. Hutchinson, 1809 Capitol Ave., Omaha, Neb.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Annual convention September 8-11, Hotel Sherman, Chicago.

MASTER BOILER MAKERS' ASSOCIATION.—Harry D. Vought, 26 Cortlandt St., New York, N. Y.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meeting second Tuesday in month, except June, July, August and September. Copley-Plaza Hotel, Boston, Mass.

NEW YORK RAILROAD CLUB.—H. D. Vought, 26 Cortlandt St., New York. Meeting third Friday each month, except June, July and August at 29 West Thirty-ninth Street, New York.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgreb, 623 Brisbane Building, Buffalo, N. Y. Regular meetings, January, March, May, September and October.

PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal Regular meetings second Thursday of each month in San Francisco and Oakland, Cal., alternately.

RAILWAY CLUB OF GREENVILLE.—F. D. Castor, clerk, maintenance of way department, Bessemer & Lake Erie, Greenville, Pa. Meeting last Friday of each month, except June, July and August.

RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Regular meeting fourth Thursday in month, except June, July and August. Fort Pitt Hotel, Pittsburgh, Pa.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings second Friday in each month, except June, July and August.

SOUTHEASTERN CARMEN'S INTERCHANGE ASSOCIATION.—J. E. Rubley, Southern Railway shops, Atlanta, Ga.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, 1177 East Ninety-eighth Street, Cleveland, Ohio. Annual meeting September 15-18, 1925, Chicago.

WESTERN RAILWAY CLUB.—Bruce V. Crandall, 189 West Madison Street, Chicago. Regular meetings third Monday in each month, except June, July and August.

Supply Trade Notes

Thomas J. Hyman, secretary and treasurer of the Illinois Steel Company, Chicago, died on July 5.

Charles T. Westlake, chief mechanical engineer of the Commonwealth Steel Company, St. Louis, Mo., died on July 22.

L. J. Ferderber has been appointed assistant to the first vice-president of the General American Tank Car Corporation, Chicago.

S. H. Worrell has been appointed district sales manager of the Detroit Seamless Steel Tube Company, with headquarters at Detroit, Mich.

T. V. Buckwalter, chief engineer of the Timken Roller Bearing Company, Canton, Ohio, has been elected vice-president in charge of engineering.

The Ajax Manufacturing Co. has removed the Cleveland, Ohio, office to its new plant on Chardon road near Euclid avenue, Euclid, Ohio, a suburb of Cleveland.

Carl A. Methfessel, manager of sales of the eastern district of the Duff Manufacturing Company, New York, died on July 22 at his home in Ridgefield Park, N. J.

Edward Payson Bigelow, sales agent for the American Steel Foundries Company, New York, died on July 20 at his home in New York from apoplexy, at the age of 81.

H. E. Passmore, formerly salesman of the Grip Nut Company at Columbus, Ohio, has been appointed sales manager of the Davis Brake Beam Company, Pittsburgh, Pa.

The National Forge Company, Louisville, Ky., has appointed E. H. & R. W. Benners as its representative in New York, for the sale of its knuckle pins and "S" and "Z" irons.

E. P. Blanchard, advertising manager of the Bullard Machine Tool Company, Bridgeport, Conn., has been appointed also assistant sales manager, with headquarters at Bridgeport.

Herbert G. Cook has been appointed Pacific Coast representative of the Railway Steel-Spring Company, New York. Mr. Cook's headquarters are at 582 Market street, Hobart building, San Francisco, Cal.

L. W. Grout, vice-president and sales manager of the Keating Valve Company, Springfield, Mass., for the past three years, has joined the sales organization of the Bridgeport Brass Company, Bridgeport, Conn.

H. E. Passmore has been appointed sales manager of the Davis Brake Beam Company, with headquarters at 1602 Oliver building, Pittsburgh, Pa. Mr. Passmore was formerly in the employ of the Grip Nut Company.

The E. L. Essley Machinery Company, Chicago, has been appointed exclusive agent for the Buffalo Forge Company, Buffalo, N. Y., to sell punches, shears, bar cutters, slitting shears and beam shears in Chicago territory.

The Ypsilanti Foundry Company, Ypsilanti, Mich., manufacturers of piston rings, has awarded a contract for a new machine shop to the Austin Company, Chicago. The building will be a two-story structure, 50 ft. by 100 ft.

Otis B. Duncan, 53 West Jackson boulevard, Chicago, has been appointed representative for the Chicago territory of the Johnston Manufacturing Company, Minneapolis, Minn., manufacturers of industrial oil-burning equipment.

The Johnston Manufacturing Company, Minneapolis, Minn., manufacturers of industrial oil-burning equipment, has appointed Otis B. Duncan, 53 West Jackson boulevard, Chicago, as representative for the Chicago territory.

C. W. Moore, 1523 Candler building, Atlanta, Ga., is representing the Goddard & Goddard Company in the southeastern territory covering North Carolina, South Carolina, Georgia, Florida, Alabama and Tennessee west to the Tennessee river.

Walter T. Comley has been elected vice-president in charge of service and production, and Adam P. Arnold, secretary and treas-

urer of the Franklin Railway Supply Company, Ltd., of Montreal, Canada. Leland Brooks, vice-president and treasurer, has resigned.

A sales and service branch office has recently been opened by the DeVilbiss Manufacturing Company, Toledo, Ohio, at 4614 Woodward avenue, Detroit, Mich., where a display and stock ot the complete DeVilbiss spray-painting equipment will be carried at all times.

The American Manganese Steel Company has opened a new plant at Los Angeles, Cal., which gives the company facilities for producing about 25,000 tons of manganese steel castings annually. The new plant will begin production at the rate of 100 tons a month.

J. C. Dawes, formerly with the Weldcraft Company, Pittsburgh, Pa., has been appointed a sales representative at the Pittsburgh branch of the International Oxygen Company, Newark, N. J. L. W. McCullough has been appointed sales representative for the branch at Toledo.

C. W. Marshall has been appointed eastern sales manager of the Sunbeam Electric Manufacturing Company, Evansville, Ind. Mr. Marshall will have his office in the Grand Central Terminal, New York. He was formerly Chicago district manager of the American Arch Company, New York.

The Union Tank Car Company has awarded a general contract to the Hughes-Foulkrod Company, Pittsburgh, Pa., for a car construction, repair and conditioning plant at Whiting, Ind., including a foundry, machine shop, power plant, wheel shop, and other structures; to cost approximately $1,700,000.

R. L. M. Taylor has been appointed district sales representative of the New York State and Eastern Pennsylvania territory, known as the Reading district of the Reading Iron Company, Reading, Pa. Mr. Taylor joined the Reading Iron Company one year ago, after serving for five years with the A. M. Byers Company.

The Dempsey Furnace Company, Jersey City, N. J., has been consolidated with the W. N. Best Corporation, 11 Broadway, New York City. The combined furnace business of the two companies will in future be operated as the Dempsey furnace division of the W. N. Best Corporation under the personal direction of H. B. Dempsey.

Charles E. Miller has been appointed representative in the Chicago district of the Premier Staybolt Company, Pittsburgh, Pa., succeeding L. W. Widmeier, resigned. The Chicago office of the company is now located at 548 Railway Exchange building. C. S. Carter has been appointed northwestern representative, with office at 752 McKnight building, Minneapolis, Minn.

B. A. Tozzer, manager of the Cleveland office of the Niles-Bement-Pond Company, New York, has been appointed sales manager of the New York office. A. E. R. Turner, in charge of the office at Walkerville, Can., succeeds Mr. Tozzer at Cleveland. Sydney Buckley, chief engineer at Philadelphia, Pa., has been appointed works manager of the crane works at Philadelphia, to succeed V. O. Strobel, resigned.

Raymond B. Hosken, assistant to the vice-president in charge of sales of the Sullivan Machinery Company, Chicago, has been promoted to general sales manager. He entered the employ of the Sullivan Machinery Company in the local sales department in Chicago after graduating from the University of Michigan in 1910. In 1914 he was promoted to Australasian manager, with headquarters in Sydney, N. S. W., and in 1921 he was promoted to assistant to the vice-president in charge of sales at Chicago, which position he held until his recent promotion.

Henry S. Mann, for many years district manager in charge of the Chicago office and shops of the Metal & Thermit Corporation, has resigned to become district sales manager of the Standard Stoker Company, Inc., New York. Mr. Mann will have his headquarters in the McCormick building, Chicago. Previous to entering the service of the Metal & Thermit Corporation he had been connected with a number of railways, serving as a locomotive engineer with the Boston & Maine, the Northern Pacific, the Atchison, Topeka & Santa Fe and the Wabash. He has served as a director of the National Railway Appliance Association of Chicago; vice-president of the American Welding Society and vice-president of the International Railroad Master Blacksmiths' Supplymen's Association.

W. D. Horton, western railway representative of the Murphy Varnish Company at Chicago, has been appointed manager western railway sales, with headquarters at 50 West Twenty-second street, Chicago. From 1908 to 1914 he was associated with the Railway Age as traveling subscription representative and on April 1, 1914, was appointed circulation manager, which position he held until March 1, 1919, when he resigned to go as district railway sales manager to the Patton Paint Company. On December 1, 1919, he resigned to become associated with the Murphy Varnish Company as western railway representative, which position he held until his recent promotion. Mr. Horton has had a wide selling experience, having spent several years previous to 1908 selling various commodities, such as stationary engines, boilers, woodworking and other machinery. In this work he traveled extensively in North America, the West Indies and in Central and South America.

John F. Schurch, vice-president of Manning, Maxwell & Moore, Inc., has been elected president to succeed John M. Davis, who has resigned to become president of the Delaware, Lackawanna & Western. Mr. Schurch graduated from the University of Minnesota in 1893. The same year he entered the service of the Minneapolis, St. Paul & Sault Ste. Marie, where he served consecutively in the office of the auditor, the general superintendent and in the transportation department, resigning in 1905 after having attained the position of chief clerk to the vice-president. He was then associated with the Railway Materials Company of Chicago until February, 1914, when he was elected vice-president of the Damascus Brake Beam Company, with office in Cleveland, Ohio. The following June he was elected president of the same company, which position he resigned later in the same year and was elected vice-president in executive charge under President T. H. Symington, of the T. H. Symington Company. In June, 1922, Mr. Schurch left the Symington Company to become a vice-president of Manning, Maxwell & Moore, Inc., in charge of sales in the middle west and the west, with headquarters in Chicago. Mr. Schurch served in 1922 as president of the Railway Supply Manufacturers' Association, which had in charge the exhibits at Atlantic City in connection with the meetings in June of Division V—Mechanical, and Division VI—Purchases and Stores, A. R. A.

J. F. Schurch

Master blacksmiths to visit machine tool exposition

An invitation to attend the second exposition of forging machines and bolt and nut machinery which is being held at the plant of the National Machinery Company at Tiffin, Ohio, August 21 to 26, inclusive, has been extended to the International Railroad Master Blacksmiths' Association, which is holding its annual convention in Cleveland, Ohio, August 18, 19 and 20. The first day of the exposition, Friday, August 21, has been set aside as master blacksmiths' day. A large part of the work to be demonstrated will be of special interest to members of the Blacksmiths' Association, and special arrangements have been made for the transportation by special train of the members and their families between Cleveland and Tiffin.

This exposition is the second of its kind to be conducted by the National Machinery Company. The first was held 15 years ago. It is planned to have a total of 62 machines, many of which are of new design, tooled up and in operation. The exhibit will contain a complete line of the National Machinery Company's forging machines, each of which will be in actual operation on various kinds of forging work. There will also be a complete nut and bolt plant in operation, in which will be shown a number of designs which have recently been developed.

Trade Publications

PULLEY GRINDERS.—Circular F descriptive of a new pulley grinder designed for finishing the face of belt surface of metal pulleys from the rough after chucking the holes, has been issued by the Graham Manufacturing Company, Providence, Rhode Island.

THE DRILL FOR TODAY.—In a 16-page pamphlet the Detroit Twist Drill Company, Detroit, Mich., presents an account of the conditions leading to the development of the rolled type of twist drill. It is an interesting story containing much information of value to the user of drills.

WHAT RUST CAN DO.—The Detroit Graphite Company has issued a folder showing various types of structures exposed to the elements and emphasizing the deterioration that occurs unless they are properly protected, setting forth the merits of its Degraco paint for this purpose.

GRINDING AND POLISHING MACHINES.—The Builders Iron Foundry, Providence, R. I., and its associate, the Diamond Machine Company, have issued a catalogue descriptive of a new line of belt and motor-driven ball bearing grinders and polishing machines and swing frame grinders.

LEDRITE ROD-O-GRAPH.—The second edition of the Ledrite Rod-o-graph, which provides in chart form a convenient way to figure the weight of brass rod required to make 1,000 screw machine parts to known dimensions, has been issued by the Bridgeport Brass Company, Bridgeport, Conn.

DODGE SHOP FACILITIES.—The engineering, foundry and machine shop facilities available for the manufacture of its special machinery and equipment are visualized in a book recently issued by the Dodge Manufacturing Corporation, Mishawaka, Ind. A wide range of special equipment is also shown.

WHEEL TRUING BRAKE SHOES.—A 12-page, illustrated brochure descriptive of the wheel truing brake shoe designed to remedy flat wheels, grooved tires, long flanges and deformities to which wheels are subject in both steam and electric service, has been issued by the Wheel Truing Brake Shoe Company, Detroit, Mich.

AIR COMPRESSORS.—The latest types of Tilghman air compressors and vacuum pumps are described and illustrated in Catalogue No. C25 which has recently been issued by the Tilghman's Patent Sand Blast Company, Ltd., Broadheath, Manchester, England. Air compressing plant design is also briefly described in this catalogue.

VISES.—A 56-page illustrated price list descriptive of the particular features of Prentiss vises, has been issued by the Prentiss Vise Company, New York. The new collar fastening for screws, designed to fasten the screw to the front jaw and then draw it out when the screw is turned to open the vise, is also illustrated and described.

GRINDING WHEEL STANDS.—The characteristic features of the Norton motor driven grinding wheel stands and specifications are given in a 20-page brochure which has been issued by the Norton Company, Worcester, Mass. The Norton combination protection and dust hoods, cylinder chucks and grinding wheel dressers are also briefly described.

REAL PRODUCTION TOOLS.—Under this title a series of illustrated booklets is being issued by the Goddard & Goddard Company, Detroit, Mich., describing the various types of special milling cutters and metal cutting saws manufactured by that company. A brief description of the types is supplemented by information as to the proper application to different classes of work.

ROTARY SHEARS.—Catalogue No. 80 describing in a comprehensive manner the various sizes and types of, and the different attachments provided for Quickwork shears and indicating how the machines operate and how the material is handled into them, has been issued by the Quickwork Company, St. Marys, Ohio. The catalogue is 9 in. by 11 in. and is attractively bound in leather, with gold lettering.

RECLAIMING SCRAP CAR AXLES.—The reclaiming of scrap car axles as practiced by a middle western railroad shop is described in an eight-page illustrated circular recently issued by the Ajax Manufacturing Company, Euclid, Ohio. The railroad referred to makes it a practice to centralize at one point and reclaim every scrap axle available from the entire system, the needs of the road with practically all except the largest size axles being supplied from this source.

STOKERS.—A two-page illustration showing the application of the Du Pont Simplex Type B stoker to a locomotive is contained in Bulletin No. 101, which has been issued by the Standard Stoker Company, New York. The stoker, which weighs approximately 5,800 lb., is simple in application, and the only stoker parts located on the backhead of the locomotive are the small distributing valves which may be located under the fire door opening, or any other place convenient to the fireman.

TRACTORS.—The operation and control of Elwell-Parker tractors, in general, is described in the first section of a 40-page illustrated catalogue, No. 140, which has been issued by the Elwell-Parker Electric Company, Cleveland, Ohio. Separate sections are then devoted to the special features and specifications for each of the haulage units, which include all electric motor-driven, rubber-tired industrial trucks, tractors, portable cranes or special types receiving their power from storage batteries carried on them.

PUSH BUTTON OPERATED OIL SWITCH.—Bulletin No. 1048, descriptive of a new push button operated oil switch for starting squirrel cage motors and also single phase motors, has been issued by the Electric Controller & Manufacturing Company, Cleveland, Ohio. This starting switch throws the motor across the line when the "start" button is released. It is arranged for no-voltage protection or no-voltage release, as desired, and provides overload and phase failure protection by means of expansion wire temperature relays.

AUXILIARY LOCOMOTIVE.—Catalogue H, descriptive of the operation, advantages, principal details and performance of the Bethlehem auxiliary locomotive, which is a tractor truck used as the rear truck of the locomotive tender, has been issued by the Bethlehem Steel Company, Bethlehem, Pa. This unit carries an auxiliary steam engine actuated by steam from the locomotive and controlled from the cab. Its function is to add more tractive force for starting, accelerating and operating at low speeds on heavy grades.

DIESEL ENGINE BUILDING.—Bulletin No. 1040, entitled "Modern methods in Diesel engine building," has recently been issued by Fairbanks, Morse & Co., Chicago, Ill. An attempt is made in this attractive 32-page bulletin to picture the present-day engineering refinements that enter into the construction of Diesel engines and what these refinements mean to the purchaser, each step in the process of manufacture of an engine, from the selection of the raw material to the final inspection and application of the finished product, being described.

HIGH SPEED TOOLS.—The Cleveland Twist Drill Company, Cleveland, Ohio, has issued its Catalogue No. 41 in a smaller and more comprehensive form. The catalogue contains 244 pages, so arranged as to make it a quick and ready index to the various high speed tools listed, which include drills, reamers, extractors, mills, counterbores, etc., and a few special tools. Several new tools, including special drills for Bakelite and slate, a small jobbers carbon drill set, a spiral fluted shank taper and several types of reamers, have been included in the catalogue.

CHEMICAL ENGINEERS.—Railroad men, both prospective and long-time users of Dearborn chemical service, will find much of interest in an attractively prepared booklet, "A House of Chemical Engineers," recently issued by the Dearborn Chemical Company, Chicago. For many years this company has been prescribing and blending the chemicals required to correct scaling, foaming, pitting, and corroding conditions in the boilers of locomotives and power plants operated by the railroads and other industries, thus conserving fuel and rendering more permanent the investments in power plant machinery. The booklet referred to contains 39 5½-in. by 8-in. pages and presents in attractive form a pictorial record of the Dearborn plant, its laboratories, storage tanks, manufacturing department and organization. Pictures of the officers of the company, beginning with Robert F. Carr, president, are included.

Personal Mention

General

E. Von Bergen has been appointed general air brake, lubricating and steam heat engineer of the Illinois Central, with headquarters at Chicago.

John R. Jackson has been appointed engineer of tests of the Missouri Pacific, with headquarters at St. Louis, Mo., a newly created position.

E. A. Kuhn has been appointed engineer of motive power of the New York, Chicago & St. Louis, with headquarters at Cleveland, Ohio, a newly created position.

F. J. Herter has been appointed engineer of rolling stock of the New York, Chicago & St. Louis, with headquarters at Cleveland, Ohio. This is a newly created position.

A. J. Pichetto has been appointed air brake, lubricating and steam heat inspector of the Northern and Western lines of the Illinois Central, with headquarters at Chicago.

George B. Hart has been appointed assistant to the general superintendent of motive power of the Southern Pacific, with headquarters at San Francisco, a newly created position.

G. M. Wilson, superintendent, motive power shops, of the Canadian National, with headquarters at Montreal, Que., has been transferred to Stratford, Ont., succeeding John Roberts.

T. W. Kennedy has been appointed air brake, lubricating and steam heat inspector of the Southern lines of the Illinois Central and the Yazoo & Mississippi Valley, with headquarters at Memphis, Tenn.

W. B. Embury, master mechanic of the Armourdale shops of the Chicago, Rock Island & Pacific at Kansas City, Kans., has been appointed superintendent of motive power, with headquarters at El Reno, Okla.

A. McDonald has been appointed superintendent, motive power shops, of the Canadian National, with headquarters at Montreal, Que., succeeding G. M. Wilson. Mr. McDonald is 37 years of age. He was born at Stratford, Ont., and entered the service of the Grand Trunk in Stratford when he was 16. He was apprenticed to both the machinst and fitter trades, spending 7 years in acquiring both. On completion of his apprenticeship he served in those capacities until he was given a minor foremanship a few years later. In 1917 he was promoted to assistant superintendent of the shops at Point St. Charles. In 1919 he was appointed acting superintendent of motive power, Eastern lines, returning a short time later to his post as assistant superintendent at Point St. Charles, in which capacity he was serving at the time of his recent promotion.

J. F. Jennings, whose promotion to superintendent of motive power of the Michigan Central, with headquarters at Detroit, Mich., was reported in the May issue of the *Railway Mechanical Engineer*, was born on June 11, 1871, at Jackson, Mich. He entered railway service in September, 1891, as a locomotive fireman on the Lake Shore & Michigan Southern, now a part of the New York Central, and was later employed in a similar capacity on the Michigan Central. He was promoted to traveling fireman in February, 1903, and in January, 1904, was promoted to assistant traveling engineer. Mr. Jennings was promoted to road foreman of engines in May, 1905, and held that position until May, 1913, when he was promoted to assistant division master mechanic. He was promoted to division master mechanic at Bay City, Mich., in February, 1915, and held that position until October, 1919, when he was promoted to assistant superintendent of motive power. Mr. Jennings continued in that capacity until his recent promotion to superintendent of motive power.

Frank H. Becherer, who has been appointed assistant to the mechanical superintendent of the Boston & Maine, with headquartres at Boston, was born on August 23, 1882, in New York City. He graduated from high school in Indiana in 1901, and attended a Y. M. C. A. night school in Buffalo until 1906. He entered railway service in 1901, as a billing clerk on the Erie, and held this position until 1903, when he became assistant chief clerk of the car department. In 1904, he was promoted to piece work supervisor of the car department and, in 1905, to chief clerk of the department. On June 1, 1907, he resigned and went with the Pennsylvania as assistant chief M. C. B. billing clerk, and was successively until 1918, freight car repairer, freight car inspector, air brake inspector, piece work inspector of freight, traveling inspector for the superintendent of motive power, assistant foreman car inspector (freight), assistant foreman passenger cars, foreman passenger cars and foreman enginehouse, powerhouse and machine shop. On March 25, 1918, he resigned to enter the service of the Interstate Commerce Commission, Bureau of Valuation, as a junior inspector of car equipment. On October 1, 1919, he became senior mechanical engineer engaged in valuing freight, passenger, work, powerhouse and machine shop equipment and locomotives. On March 1, 1922, he resigned and entered the service of the Boston & Maine as assistant engineer, corporate engineer's office. On October 1, 1922, he became mechanical inspector, and in April, 1923, general inspector car maintenance, which position he held until June 16, 1925, when he was appointed assistant to the mechanical superintendent.

Master Mechanics and Road Foremen

W. A. King has been appointed road foreman of engines of the Seaboard Air Line, with headquarters at Wildwood, Fla.

A. Hambleton has been appointed master mechanic of the El Paso-Amarillo division of the Chicago, Rock Island & Pacific, succeeding J. C. Cole.

R. R. Harris has been appointed road foreman of engines of the Tampa & Gulf Coast and the Tampa Northern, with headquarters at Tampa, Fla.

G. A. Haslett has been appointed general road foreman of engines, Southern district, of the Seaboard Air Line, with headquarters at Tampa, Fla.

F. B. Kester, master mechanic of the Chicago & North Western at Escanaba, Mich., has been appointed master mechanic, with headquarters at Antigo, Wis.

J. S. Jones, assistant master mechanic of the Chicago & North Western at Antigo, Wis., has been appointed master mechanic, with headquarters at Escanaba, Mich.

H. M. Agin has been appointed road foreman of engines of the Florida division of the Seaboard Air Line, with headquarters at Tampa, Fla., succeeding G. A. Haslett.

E. H. Carlson has been appointed assistant master mechanic of the Fargo division of the Northern Pacific, with headquarters at Staples, Minn., succeeding J. A. Marshall.

J. C. Trigg has been appointed assistant road foreman of engines of the Florida division of the Seaboard Air Line, with headquarters at Waldo, Fla., succeeding H. M. Agin.

J. A. Marshall, assistant master mechanic of the Fargo division of the Northern Pacific at Staples, Minn., has been promoted to master mechanic of the Pasco division, with headquarters at Pasco, Wash.

J. C. Cole, master mechanic of the El Paso-Amarillo division of the Chicago, Rock Island & Pacific, with headquarters at Dalhart, Tex., has been transferred to Chickasha, Okla., succeeding A. R. Ruiter.

A. R. Ruiter, master mechanic of the Chicago, Rock Island & Pacific, with headquarters at Chickasha, Okla., has been transferred to the Kansas City Terminal-St. Louis division, succeeding W. B. Embury.

H. J. McCracken, formerly district boiler inspector of the Northern district of the Southern Pacific at Sacramento, Cal., has been promoted to assistant master mechanic of the Western division, with headquarters at West Oakland, Cal.

W. B. Embury, master mechanic of the Kansas City Terminal-St. Louis division of the Chicago, Rock Island & Pacific, with headquarters at Armourdale, Kans., has been promoted to superintendent motive power of the Second district, with headquarters at El Reno, Okla.

Car Department

W. T. Westall has been appointed assistant district master car builder (Fourth district) of the New York Central, with headquarters at Air Line Junction (Campbell street shops), Toledo, Ohio.

E. B. Dailey has been promoted to engineer of car construction of the Southern Pacific, with headquarters at San Francisco, Cal. Mr. Dailey was born on February 1, 1870, in Omaha, Neb., and was educated at Creighton College, Omaha, Neb. He entered railway service in July, 1886, as a machinst apprentice on the Union Pacific at Omaha, and was later employed as a machinist on the Northern Pacific, the Oregon Railway & Navigation Company, the Union Pacific and the Southern Pacific. In September, 1892, he was employed as a draftsman on the Union Pacific at Omaha, later being promoted to inspector of equipment. He was promoted to chief draftsman in 1903 and was later promoted to assistant mechanical engineer. In February, 1913, Mr. Dailey was appointed assistant to the director of purchases of the Southern Pacific at New York. On June 1, 1918, he was appointed first assistant manager of the Procurement section of the United States Railroad Administration at Washington, D. C. In September of the same year he returned to the Southern Pacific as corporate mechanical engineer of the lines in Texas and Louisiana. From March 1, 1920, to January 1, 1921, he was assigned to special work, on the latter date being again appointed assistant to the director of purchases of the Southern Pacific at New York. He held that position until his recent promotion to engineer of car construction.

E. B. Daily

Purchasing and Stores

A. G. Follette, supervisor of the stores catalog of the Pennsylvania, has been appointed assistant chief general material supervisor with headquarters at Philadelphia, Pa.

D. C. Curtis has been promoted to chief purchasing officer of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago. Mr. Curtis was born in 1878 at Remington, Ind., and entered railway service in 1898 as an office boy in the engineering department of the Chicago, Burlington & Quincy at Chicago. He was transferred to the mechanical department in 1899 and in 1904 was placed in charge of the piece work department. In 1907 Mr. Curtis was transferred to the stores department and was promoted to inspector of stores in 1909. He was promoted to traveling storekeeper in 1914 and held that position until 1919, when he was appointed supervisor of stores of the Northwestern region under the United States Railroad Administration. He was appointed general storekeeper, lines east, of the Chicago, Milwaukee & St. Paul, with headquarters at Milwaukee, Wis., in 1920. and held that position until his promotion to chief purchasing officer.

D. C. Curtis

W. B. Hall, whose promotion to general purchasing agent of the Denver & Rio Grande Western, with headquarters at Denver, Colo., was reported in the May issue of the *Railway Mechanical Engineer,* was born on March 7, 1877, at Salt Lake City, Utah. He entered railway service in 1891 as an office boy in the motive power and car department of the Rio Grande Western, now a part of the Denver & Rio Grande Western. He was later promoted to clerk, which position he held until 1895, when he was promoted to stationer. Mr. Hall was appointed a clerk in the stores department in 1899 and in the following year was promoted to chief clerk to the purchasing agent. He was appointed stationer of the Denver & Rio Grande, with headquarters at Denver, Colo., in 1903, and in 1905 was promoted to division storekeeper, with headquarters at Salt Lake City, Utah. Mr. Hall was promoted to general storekeeper in July, 1908, and held that position until his recent promotion to general purchasing agent.

W. B. Hall

N. M. Rice, general purchasing agent of the New York, New Haven & Hartford, at New Haven, Conn., has been elected vice-president in charge of purchases and stores, with the same headquarters. Mr. Rice was born on December 28, 1863, at Rome City, Ind., and was educated in the public schools of that city. He entered railway service in May, 1887, as a brakeman on the Gulf, Colorado & Santa Fe, and from this time until April 1, 1901, he held several positions in the transportation and stores department. From April, 1901, to April, 1903, he was assistant general storekeeper of the Atchison, Topeka & Santa Fe Coast Lines, at which time he became general storekeeper of the same road in charge of material, fuel and stationery. He held this position until November 13, 1913, when he was appointed general purchasing officer of the St. Louis & San Francisco, with headquarters at St. Louis, Mo. From 1915 to 1916, he was third vice-president in charge of purchases, and from 1916 to 1919, was second vice-president of the same road. From 1919 to 1920, he was vice-president of the Pierce Oil Corporation, and, in 1920, became general purchasing agent of the New York, New Haven & Hartford, and also of the Central New England and New England Steamship Company.

N. M. Rice

Shop and Enginehouse

J. D. Bumcrots, lead machinist in the back shop of the Kansas City Southern at Pittsburg, Kans., has been appointed to the newly created position of shop efficiency supervisor.

John Roberts, superintendent, motive power shops, Canadian National, at Montreal, Que., has been appointed general supervisor of shop methods, with headquarters at Montreal, a newly created position.

Railway Mechanical Engineer

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Request for change of address should reach the New York office two weeks before the date of the issue with which it is to go into effect. It is difficult and often impossible to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, be sure to send us your old address as well as the new one.

Subscriptions, including the eight daily editions of the Railway Age published in June, in connection with the annual convention of the American Railway Association, Mechanical Division, payable in advance and postage free: United States, Canada and Mexico, $3.00 a year; foreign countries, not including daily editions of the Railway Age, $4.00. When paid through the London office, 34 Victoria Street, S. W. 1, 17s. 0d. Single copy 35 cents or 1.6d.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulation (A. B. C.).

Railroad Saves $21,500 Using Ryerson Spring Shop Equipment

Ryerson Flue Shop Equipment is also saving money for the railroads. Let us send you bulletins covering this complete line of equipment.

ONE eastern railroad, by using Ryerson Standard Spring Shop Equipment, saved $21,500 in 2½ years after amortizing the cost of the entire equipment. Another road reduced its locomotive spring cost from $4.40 to $3.20 per hundred lbs.

One important machine of the Ryerson Standard Spring Shop Equipment is the Universal Spring Former. Absolute fit and perfect camber is produced in a single operation. Perfectly fitted springs made with this machine increased the life of springs on one large trunk line, over 300%.

Send for the facts on this equipment. It will mean a big saving on your spring costs. Ask for Bulletin 20,201.

Railway Mechanical Engineer

Vol. 99 September, 1925 No. 9

Using the Railway Mechanical Engineer

Just how can the best use be made of the *Railway Mechanical Engineer?* Each number is brimful of constructive suggestions and facts which are of vital interest to mechanical department officers and foremen. We have had a number of requests in recent months for suggestions as to the subjects to be discussed at staff meetings or before foremen's clubs. After the August issue of the *Railway Mechanical Engineer* was mailed we wrote to the author of the letter on page 495 which is signed "Output." Here is an extract from his reply. "As you probably know, one of ———'s methods of keeping his foremen from senile decay is to mark an article in some mechanical magazine and request a paper as to its merits to be read at one of the foremen's meetings. That is the way 'Output' came to life." We find that a growing number of master mechanics, shop superintendents and general foremen are adopting the practice of referring to different articles in the paper and asking those associates whose departments the articles concern, to express an opinion as to the value of the articles and their application to their peculiar conditions. Indeed, there are superintendents of motive power who regularly ask some of their subordinates for opinions on articles which are published in the technical papers or on addresses or reports that are made before railroad clubs or technical associations or societies. There is much to commend this practice. It stimulates and inspires officers and foremen to crystallize their thinking and to search out and adopt the very best methods and practices. Where the reports or findings are presented at a meeting of the foremen or local officers, the resulting discussion is quite likely to develop features and improvements which were not mentioned in the original articles or suggested by the man reporting upon it. There is always great value in open and full and free discussion on matters of this kind. We hope that more and more of the mechanical officers will use the *Railway Mechanical Engineer* in this way.

The foreman's responsibility

The third prize article in the *Railway Mechanical Engineer* competition on the foreman and his responsibilities appears elsewhere in this number. It was written by J. W. Murphy, general foreman of the Boston & Albany at West Springfield, Mass. Mr. Murphy approaches the question in a very different way from "Bill Brown" in the first prize article, which was published in our June number and which seems to have started a real controversy; nor is the treatment similar to that of the second prize article by John Linn of the Santa Fe, which was printed in our August number.

Mr. Murphy's article challenges attention from several viewpoints. We often hear it said that a cause or an organization cannot stand still; it must go forward or backward. To what extent is it true that foremen, when once appointed to that position, settle down to routine work and fail to make an effort to keep abreast of the times and to improve themselves by study and observation in order to give a larger service to their employers, as well as the men under them, and to fit themselves for larger responsibilities? If they do stand still they will go backward, for the entire conception of relations in industry and transportation has been changing and is steadily rising to higher ideals. Mr. Murphy indicates that a foreman should "make himself more fit each day to render that service in the most effective way." The inference is that the foreman, whether newly appointed or old on the job, should constantly study and strive to make his efforts more effective; otherwise he will stagnate and fail in his duty to his employer, the employees and the public. Is this conception too idealistic? In a way it agrees closely with the underlying spirit of the other two prize winning articles by "Bill Brown" and Mr. Linn. Practical results are what we are after in this materialistic age. Can they be secured by foremen who are dominated by a spirit of service to their fellows?

Purpose of shop schedules

When scheduling systems for repair work were first introduced in railway shops, they were looked on with a great deal of skepticism by the supervisory forces. They were considered the brain child of some efficiency expert who did not know the true conditions of the shops. But, after a great deal of explaining and persuasion, these same sceptics began to realize that those responsible for the introduction of shop schedules did know the true condition of the shops and were trying to bring order out of chaos. In order to increase production, reduce repair costs and still maintain quality of workmanship, a system must be devised whereby every department, every supervisor and every workman must know what to do, when to do it, and how to do it, so that the system may properly function. One of the problems facing the mechanical officers today is to lessen the large amount of unessential detail work with which the average shop foreman has to contend. It is obvious that attention to details which can better be handled automatically by system is not the function of the foreman and besides it is absolutely impossible for one man to know intimately all the details of the work carried on in a large railroad shop. By making each workman or group of workmen in each craft responsible for the completion of a certain job at a predetermined time, the supervisory officers are relieved of a mass of details enabling them to give their attention to the more important problems of personnel and organization. A

scheduling system which functions properly, will quickly indicate what departments need strengthening. The schedule boards indicate infallibly where delays periodically or persistently occur. Friction between departments is almost entirely eliminated as it is not possible to unload on one department causes for delay which belong to another. Thus, it can be said that scheduling eliminates one of the human frailties of "passing the buck to the other fellow"—as the constant reappearance of the daily delay report stimulates foremen and workmen to establish a record of performance on merit alone instead of concealing their deficiencies at the expense of their fellow workmen.

Locomotive efficiency improves

At the World's Fair held in St. Louis in 1904, several types of locomotives were given exhaustive tests in a newly designed test plant constructed as a part of the Pennsylvania Railroad exhibit. The official report of these tests was published in 1905, exactly 20 years ago, and an interesting and highly illuminating indication of the advance in locomotive design and construction since that time can be obtained by comparing the figures then obtained with locomotive test plant results secured in 1925.

One of the locomotives tested at St. Louis in 1904 was a heavy Consolidation type designed for freight service and considered thoroughly modern at that time. For purposes of comparison, the Missouri Pacific three-cylinder Mikado type locomotive, which was tested at the Altoona test plant during the past year, may be selected. The Consolidation weighed 173,000 lb. on the drivers and developed a maximum drawbar pull of 22,078 lb., as opposed to 244,500 lb. weight on the drivers and 61,847 lb. drawbar pull for the Mikado. In other words, while the weight on the drivers of the modern locomotive has increased 41 per cent, the drawbar pull available for hauling freight trains has increased 180 per cent or nearly trebled.

The effect of improved modern locomotive design on the coal pile is strikingly manifested by the relative figures for coal consumption. The 1905 Consolidation consumed from 2.9 to 5.4 lb. of dry coal per indicated horsepower hour dependent upon the load conditions, as against 2.1 to 3.8 lb. for the 1925 three-cylinder Mikado. It will therefore be observed that the coal consumption per unit of power developed is decreased almost one-third in the modern locomotive.

The real significance of what locomotive designers have accomplished, however, is shown in a comparison of the figures for efficiency. The maximum boiler, machine and overall efficiencies of the Consolidation were 78.9, 84.8 and 5.1 per cent respectively, the corresponding efficiencies for the three-cylinder Mikado being 83, 92 and 7.3 per cent. The designer's work in getting increased utilization of the heat in the coal is indicated by this increase of 4.1 per cent in boiler efficiency. In spite of the increased size, weight and complication of the modern locomotive with consequent increased frictional losses and lubrication difficulties, the machine efficiency has been increased 7.2 per cent. The increase of 2.2 per cent in overall efficiency while small numerically means a saving of many thousands of tons of coal annually.

The statement is made that many mechanical department officers deprecate the ultimate economy of fuel-saving accessories on locomotives and do not favor the application of these devices because they add to the cost of maintenance and increase the possibility of failures on the road. That any considerable number of mechanical department officers hold this view may well be doubted, for ample evidence is available that the practice of many railroads in applying these devices has paid big returns on the investment. With present fuel and labor costs, it pays to utilize the most efficient locomotives available.

The opinion of one enginehouse foreman regarding the improved performance of modern locomotives is indicated in the following unsolicited comment: "If the modern locomotive were as wasteful of coal as its predecessor of 20 years ago we would have to hook a coal car on behind the tender to carry the extra fuel." This statement is an exaggeration which, however, shows the real opinion of a railroad mechanical officer who sees the effect of improved locomotive design including fuel-saving devices on the coal pile. The question may well be asked, "How many of those old 1905 locomotives are still in operation?" With the modern locomotive consuming one-third less coal per horsepower hour developed than is being burned by locomotives of earlier and relatively inferior types, it is plain that the latter should be retired as fast as possible or rebuilt and thoroughly improved.

Foremanship training

The chamber of commerce at Milwaukee, known as the Milwaukee Association of Commerce, has for several years conducted a Foremen's Safety School under the direction of the Safety Division of the Association. The success of the school, the work of which is outlined in a communication on another page of this issue from Harry J. Bell, manager of the Safety Division, is undoubtedly due in a large measure to the broad and comprehensive way in which this whole problem of safety has been approached. Indeed, the people in Milwaukee in referring to the work of the school characterize it as "wholesaling safety." The theory on which it is based seems to be that real progress can be made not by treating a disease, but by getting at the fundamental causes and eliminating it entirely. The purpose therefore seems to be not to go into a lot of details as to the prevention of accidents, but rather to improve the leadership ability of the foremen, in order that they may help and inspire the men to a larger and more intelligent interest in their work. This is reflected in better morale and greater efficiency. It means also that the foremen must understand thoroughly the fundamental principles affecting production, employment, labor turnover, leadership, etc. It is understood that a number of railroad foremen have taken this course or are enrolled in it. It would be interesting to know just what benefits they have received in the direction of improving their leadership ability.

Are there not many other industrial communities in which large railroad shops are located where the Milwaukee method could be reproduced to advantage by getting the local chamber of commerce or other civic bodies interested? The industries and the railroads have a common problem to solve. The principles underlying successful foremanship are the same in both fields and getting the foremen together to discuss these principles, where it is possible, might bring about a closer and more cordial relationship between the railroads and the industries in the particular community.

There is also another public source from which some of the railroad groups can undoubtedly receive help in foremanship training. Reference was made in the survey on foremanship training in the June number of the *Railway Mechanical Engineer* to the study course which is being followed by the foremen of the Lehigh Valley at Sayre, Pa., which was furnished by the Engineering Extension Department of State College, Pennsylvania. Some of our friends in the Grand Trunk Western shops at Battle Creek, Mich., have advised us that a representative of the Department of Industrial Education of the

University of Michigan conducted a most effective course in foremanship training in Battle Creek last year. Undoubtedly a goodly number of the other state universities are prepared to give assistance in this direction. Indeed, an open forum discussion on foremanship training at the Railroad Y. M. C. A. Summer School at Blue Ridge, N. C., last month developed the fact that two Railroad Y. M. C. A. secretaries are negotiating with representatives of state universities to help them put on such a course this next season for the foremen and supervisory officers in their particular localities. One of these Y. M. C. A. secretaries is located in New Hampshire and the other one in Georgia. The Industrial Department of the Y. M. C. A. has also promoted courses on foremanship and many of the larger Y. M. C. A's throughout the country include such courses in their educational program.

It is evident that a number of railroads are going to tackle this problem seriously during the next season; there are several ways in which to approach this task, depending upon local conditions and available facilities. The above suggestions cover only a few of the possible approaches.

New Books

LAYING OUT FOR BOILER MAKERS: *Fourth edition, revised. 8½ in. by 12 in., 385 pages, 550 illustrations. Published by the Simmons Boardman Publishing Company, New York. Price $8.00.*

The fourth edition of this book, which has been well known for many years in the field of boiler making, has been completely revised and amplified. New chapters have been added on the layout of return tubular boilers and on the locomotive boiler. These chapters were specially prepared by authorities on the subject and are the last word in modern layout practice. The principles of triangulation and projection are discussed in the opening chapter of the book and applied to practically every form of layout work that is required in a modern shop. A chapter is devoted to marine boiler construction with the practice of one of the largest shipyards in the country taken as a basis. A chapter is devoted to layout problems, including uptakes, Y problems, stacks, tanks, breeching, tapering sections, chutes, buoys, transition pieces, pipe layouts, elbows, hoppers, hoods, ventilators and numerous other miscellaneous problems. The book has been divided into fourteen chapters and these have been completely cross-indexed for ready reference to any problem that might come up in the course of work in nearly any plate or boiler shop.

THE RESISTANCE OF EXPRESS TRAINS, *by C. F. Dendy Marshall, M. A. Bound in cloth, 9 in. by 12 in., 86 pages, 55 illustrations and diagrams. Published by the Railway Engineer, London, Eng. Price 20 shillings.*

The subject of train resistance is extremely interesting and of practical importance to railroad men. Although considerable experimental work has been performed relative to this problem comparatively little that has been written about it has been published in book form. The author, in writing this book has sought to provide a book from which the important results of numerous tests and experiments may be obtained.

The book contains 17 chapters including such subjects as internal resistances of cars, track resistance, effect of acceleration, gradients, curves and winds. There are five chapters devoted to the discussion of wind resistance in which the effect of oblique winds, direct winds and resultant winds are considered. Three additional chapters are also included in which the author has reviewed the recent developments and findings on train resistance, a summary of formulas, and a description of the dynamometer car used on the Great Western Railway of England.

The author has made a number of suggestions relative to new lines of experiments which can be followed without much difficulty. He has also described a number of modifications applicable to standard practice that are aimed to bring about better running conditions and economy in the use of fuel. Although the book is written primarily from the standpoint of railway practice in Great Britain, practically all of the conditions described and the treatment of the various problems of train resistance are applicable to railway practice in this country.

What Our Readers Think

Who can answer this question?

OMAHA, Neb.

TO THE EDITOR:

We have recently had several inquiries relative to the following question: "How does fire affect steel underframes of box cars that have had the woodwork burned off?"

I have been trying to procure information relative to this from several railroad men, but they have not had any experience that would warrant their giving me any authentic information. As the *Railway Mechanical Engineer* is in a position to gather the latest that is to be obtained in railroad practice, I am appealing to you. Can you help me?

F. W. BASON.
Manager, Railway Educational Bureau.

Reclaiming asbestos locomotive lagging

MINNEAPOLIS, Minn.

TO THE EDITOR:

I am a reader of your magazine and have found many valuable and interesting articles for locomotive and car men of a practical nature. I notice also that a good many questions are answered by the readers as well as the editorial staff, and this leads me to ask for a practical method of reclaiming asbestos locomotive lagging. My principal trouble seems to be in applying sufficient pressure in moulding the new blocks, and I would appreciate any suggestions along the lines of a practical home made press.

THEO. NYGREN,
Locomotive carpenter foreman, Soo Line.

Treated water and firebox renewals

DECATUR, Ill.

TO THE EDITOR:

I have just read with interest the editorial in the August *Railway Mechanical Engineer* relative to the service given by a firebox on a Pacific type locomotive on the Southern Pacific, the firebox having lasted somewhat over 12 years and the unusual length of service being attributed to hot water washing of boilers and treatment of feedwater.

I think there are few that realize the possibility of increasing firebox life through hot water washout plants and particularly through the use of treated water. Below are statistics in regard to firebox life on some of the

larger Wabash class of power and which may be of interest to the readers of the *Railway Mechanical Engineer*.

Our firebox renewals are very light and we attribute this almost entirely to the fact that all locomotive boiler water used on the railroad is treated, with the exception of the few waters that contain a little natural sodium carbonate or soda ash. Our method is to treat the water at the roadside supply tank with enough soda ash to neutralize any sulphate hardness in the water and provide a slight excess of soda ash. The treatment was started in 1912 and extended gradually until it was completed in 1916.

In 1912 we purchased 16 Pacific type passenger locomotives with 24-in. by 26-in. cylinders, total weight of engine and tender 423,840 lb. Only six of these have received fireboxes and three of them were applied before treated water was used on the divisions on which they were running. In the same year 63 Mikado locomotives were purchased with 26-in. by 30 in. cylinders, weight of engine and tender 423,840 lb. Of these 63 engines, some of which were run for several years without treated water, only eight have received fireboxes, and these eight were applied in 1915 when they were converted from saturated steam engines to superheated engines, it being thought advisable when we first started converting the engines to apply complete fireboxs. This practice was soon stopped and no fireboxes have since been applied to this class of locomotive.

Thirty heavy six-wheel switch engines were purchased in 1906 and 1907 and 12 similar engines in 1912. Six of the first 30 have received fireboxes but none of those purchased in 1912.

In 1917 twenty-five Santa Fe type locomotives with 29-in. by 32-in. cylinders, weight of engine and tender 592,000 lb., were placed in service, and none of these have received fireboxes or even part side sheets. These Santa Fe type locomotives have 96-in. by 120 in. fireboxes and 60-in. combustion chambers.

The very large increase in firebox life is only one of the advantages that can be obtained by water treatment, but in order to obtain the full advantage of the treatment for locomotives over any certain operating district all water that is used by them must be treated by some method that will result in the water in the boiler always showing an excess alkalinity.

W. A. POWNALL,
Mechanical Engineer, Wabash Railway.

Foremen's safety school

MILWAUKEE, Wis.

TO THE EDITOR:

The Milwaukee Association of Commerce organized, in 1920, the first full-time, budget-supported safety division in chamber of commerce history. During nearly five years of intensive operation the activities of this division have expanded to embrace practically every large employer of labor in Milwaukee and its environs; it is, furthermore, having a noteworthy effect upon industrial conditions throughout Wisconsin. Certain of its projects have attained the proportion of national institutions. An instance in kind is its Foremen's Safety School.

Proceeding on the unquestionably sound premise that 85 per cent of *industrial accidents are preventable by education*, and cognizant of the important position occupied by foremen in the modern industrial structure, this school was conceived as a means of "wholesaling" safety to the entire industrial community. It is now in its fifth season and has an enrollment of 4,538—principally foremen and forewomen. Attendance at its meetings averages 3,000!

The school each year holds six monthly gatherings and is divided into sectional meetings and general sessions, all held in the evening in the Milwaukee Auditorium, a building which is particularly suited to this purpose. Sectional meetings, in session from 7:45 to 8:30, are devoted to addresses and practical discussion of the specific, semi-technical subjects in hand, while the general sessions, from 8:45 to 9:30, are given over to speeches of universal appeal and inspirational in character. During the fifteen minute intermission between the sectional and general meetings, an industrial band provides entertainment. Exhibits, demonstrations, stereopticon and moving pictures all contribute to the success of the plan.

The school is sectionalized by industrial grouping as follows: Machine shop, sheet metal, packers and tanners, woodworking, building construction, foundry, electrical and all-trades, the latter being arranged to provide for those industries not specifically included in the special trade sections. These sections meet in eight separate halls during the forepart of the evening and join in the general meeting for the remainder of the evening. Each person enrolled is given an attendance card which is perforated to indicate presence at meetings, a master record of enrollment and attendance being maintained at the headquarters office.

Thus, with the very minimum of effort and expense, the school provides an opportunity for employers to take advantage of a constructive educational plan of tremendous value to executives and supervisors in general *and foremen in particular. For the school deals, in an altogether practical manner, with such important aspects of industrial betterment as accident prevention, production, employment, labor turnover, fire prevention and leadership.* How important it is that serious, earnest effort be directed to these problems is illustrated by the fact that Wisconsin in 1923 had 20,941 compensation cases, costing $3,719,030 and that its fire loss that year was $11,500,000!

The concluding meeting of the school takes the form of a graduation banquet at which certificates are awarded to those who meet the requirements laid down by the committees in charge of this operation, composed of 54 representatives of our leading industries. The graduates of the school now number over 4,000 and it is expected 2,000 more will graduate from the present school.

This project, like the sundry other operations of the Safety Division, is designed to develop a sense of responsibility on the part of the foremen for the safety and well-being of those who work under his direction; to inculcate in his mind a high regard for the principles and practices of safety and to make him understand that safety increases efficiency, improves morale, decreases material spoilage and aids production. That accidents are not a necessary by-product of industry and, consequently, it becomes the duty of the foreman not only to practice safety himself, but to teach it by example and precept to those with whom he has contact.

The dynamic force behind the work of the Safety Division is Frank Frey, Jr., of Geuder, Paeschke & Frey Co., manufacturers. Mr. Frey, as Chairman of the Division, is a member of the board of directors of the Association of Commerce. The Association is in affiliation with the Chamber of Commerce of the United States, the National Safety Council and the National Fire Protection Association. The extent of co-operation necessary as a means of obtaining results in its various operations, is evidenced by the fact that 71 speakers from various sections of the United States will address the sundry meetings functioned under the Division's 1924-1925 program of activities.

HARRY J. BELL,
Manager, Safety Division, Milwaukee Association of Commerce.

The foreman and his responsibility

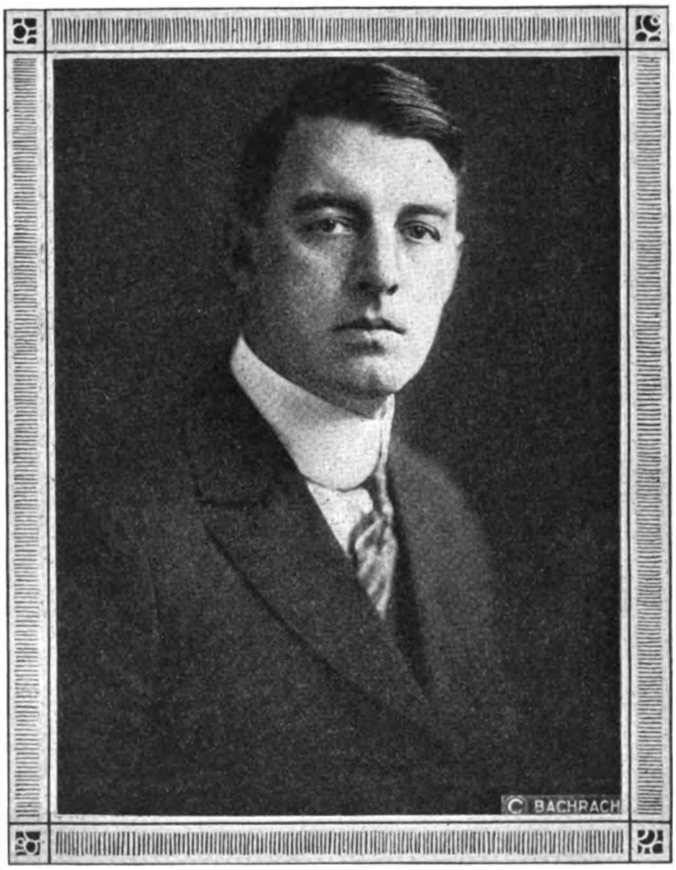
Third prize article in the competition recently held by the Railway Mechanical Engineer

By J. W. Murphy

General foreman, Boston & Albany, West Springfield, Mass.

THE foreman in any industrial organization is a connecting link between the management and the worker, and upon the character of this link depends not only the success of the whole organization, but of the foreman himself. Essentially the foreman's job is to direct his men in such a way as to obtain the greatest possible production, quality considered. The manner in which he accomplishes this object, however, has a tremendous bearing upon the soundness of the entire organization, and the cordial relations between the management and the employees.

The foreman is confronted daily with problems of a technical nature and of human relations. The first he can solve if he is thoroughly conversant with his trade, and the second if he is a real man with his heart in the right place. No man should ever consider accepting a foreman's job unless he is willing to assume the responsibility that goes with it. The national game of "passing the buck" which was so prevalent among railroad men is being eliminated, for men are coming more and more to the realization that a great deal of material and spiritual satisfaction is gained—that bigger things are in store—if the game of life is played honestly.



J. W. Murphy

Must have an ideal

A successful foreman must have an ideal and strive in the daily routine to attain that ideal; otherwise he will be a failure. There is no such thing as luck; if we look into the lives of great men we will find that all of them had an ideal in life and worked hard to realize it. That is why they were successful in whatever walk of life they moved.

The question then arises, what should be the railroad shop foreman's ideal and what should he do to attain it. His ideal should be that of service; service to his management, the public, to his workers, and to himself. His position is big, bigger and more important than that of some of his executives, for he has a broader field to serve and a great deal more is required of him. Because of this he should be fit to handle the job and make himself more fit each day to render that service in the most efficient manner.

Much has been said and written about applying the "Golden Rule," but the "Golden Rule" alone will not solve all problems; neither will it make good foremen. In my opinion there are three outstanding features which make the successful foreman and these are:

1. Certain characteristics of leadership.
2. A thorough knowledge of his trade and keeping abreast with new developments in his line.
3. Honesty to the management, to the employees, and to himself.

Must be a leader

The first of these requirements is obvious. In order to direct his men to efficient production he must be a leader, either born or developed by proper training. This is especially desirable in a railroad shop where, due to the nature of the work, systematizing is more difficult than in an industrial plant; hence more responsibility devolves on the foreman. A foreman who possesses the quality of leadership is able to organize and place his men so as to obtain maximum production with the facilities at his disposal. In many of our railroad shops today too little attention is paid by the foreman to physique, psychology, or natural aptitude of the workers. If a foreman does not give sufficient serious consideration to these characteristics of the worker, he is soon confronted with the problem of "lost motion" in his department and oftentimes he cannot locate the cause. If he would only study his men he would soon find that they work most efficiently when placed on jobs for which they have a natural aptitude. In everyday routine the average foreman does not pay much attention to these things, but the successful foreman does. A foreman who is a leader with an ideal will imbue his ideal and enthusiasm in his workers and thus develop a dependable man and an efficient organization.

A man, to be a successful foreman, must have a thorough knowledge of his trade. This is essential in order to perform his duties properly and hold the respect of his men. The type of man which is needed in our railroad shops today as foreman is one who will give a direct answer to any question pertaining to the technical side of

his work, for there is nothing which will cause a worker to lose respect for his foreman more than stalling when the answer should be forthcoming quickly. A foreman should take a broad view of his position; be open-minded in regard to new improvements and methods. The successful foreman is never the self-satisfied, know-it-all type of man. He is the man who, realizing his deficiency of knowledge on certain subjects, will study them. He is the man who will keep himself informed on new developments in the mechanical end of railroading by means of books and periodicals dealing with these subjects. By doing this he is making himself more valuable to the company, to his workers, and to himself.

Human relations

The question of human relations in a railroad shop is one of vital importance to the organization and there is no official who can do more to further good-will than the foreman. When all industry was in its infancy, it was not uncommon for the owner or manager to mingle with the workers where each could exchange his point of view and promote good relations. Today in our complex industrial organization, this is impossible and it devolves upon the foreman to familiarize himself with the policy of the management and convey this to the worker. It is up to the foreman to dispel all rumors or misunderstandings in regard to the management; it is up to him to respect and speak well of his superiors, for in this way his men will develop a respect for the offiicals and for the foreman himself. The management knows that the application of the "Golden Rule" is for the good of all concerned, but the foreman is the man who must, and the only man who can, put it across in a practical way.

What is there in a railroad shop to keep a man content and interested? He has a certain fixed rate of pay which he cannot exceed, so there is no incentive in that direction. He may become a foreman, but he has no illusions in that respect, for one in a hundred may be promoted and the opportunity does not come very often. Why doesn't he stagnate? The thing that keeps him moving is the dynamic force of good relations between his management, his foreman, and his fellow workers. The successful foreman realizes this and puts all his efforts to promote the good relations, and wherever possible to improve working conditions and make life in the shop as pleasant as possible. The successful foreman is a real man with a soul and a heart in the right place, who never forgets that his men are human and have hearts and souls. He is not the man who peddles gossip or petty little reports to his superiors, but looks on his job in a big way; in an honest and manly way.

What is the foreman going to gain by putting his best efforts into the daily grind when just "getting by" is so easy; when shirking certain responsibilities relieves him of so much strain; when "passing the buck" is so pleasant a game. The foreman's gain is twofold. First, he has the moral satisfaction that he is playing the game right; and second, when the opportunity for promotion comes it is always the man who has been doing his duty honestly every day who gets the promotion, for after all, real achievement is an accumulation of hard, earnest every-day work.

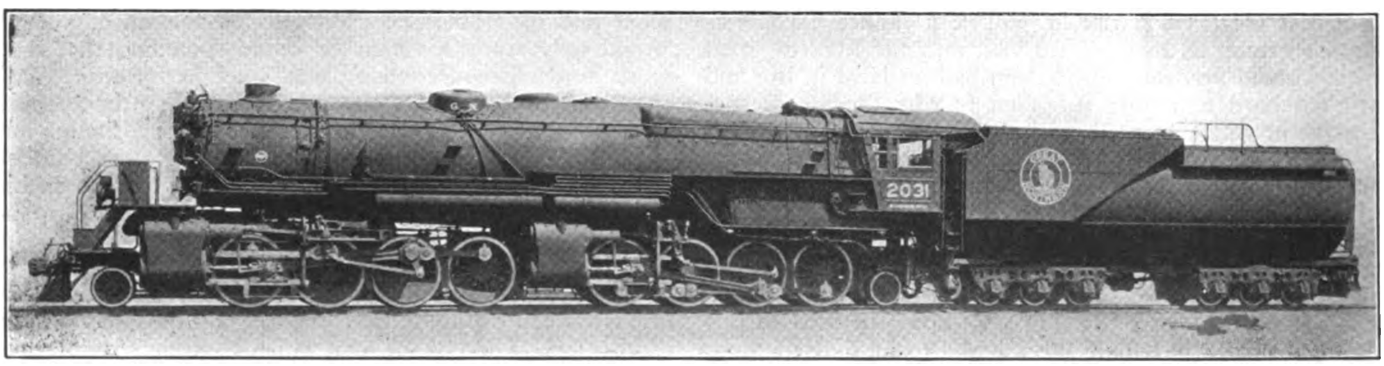
We must not forget, however, that the individual foreman alone cannot build the whole organization; that there must be co-operation from the president down; that there must be co-operation among the foremen, that the petty little jealousies among them must cease, for in the final analysis nothing is gained by them.

Which is going to succeed, stagnation or progress? I'll leave it to the foremen to solve the riddle.

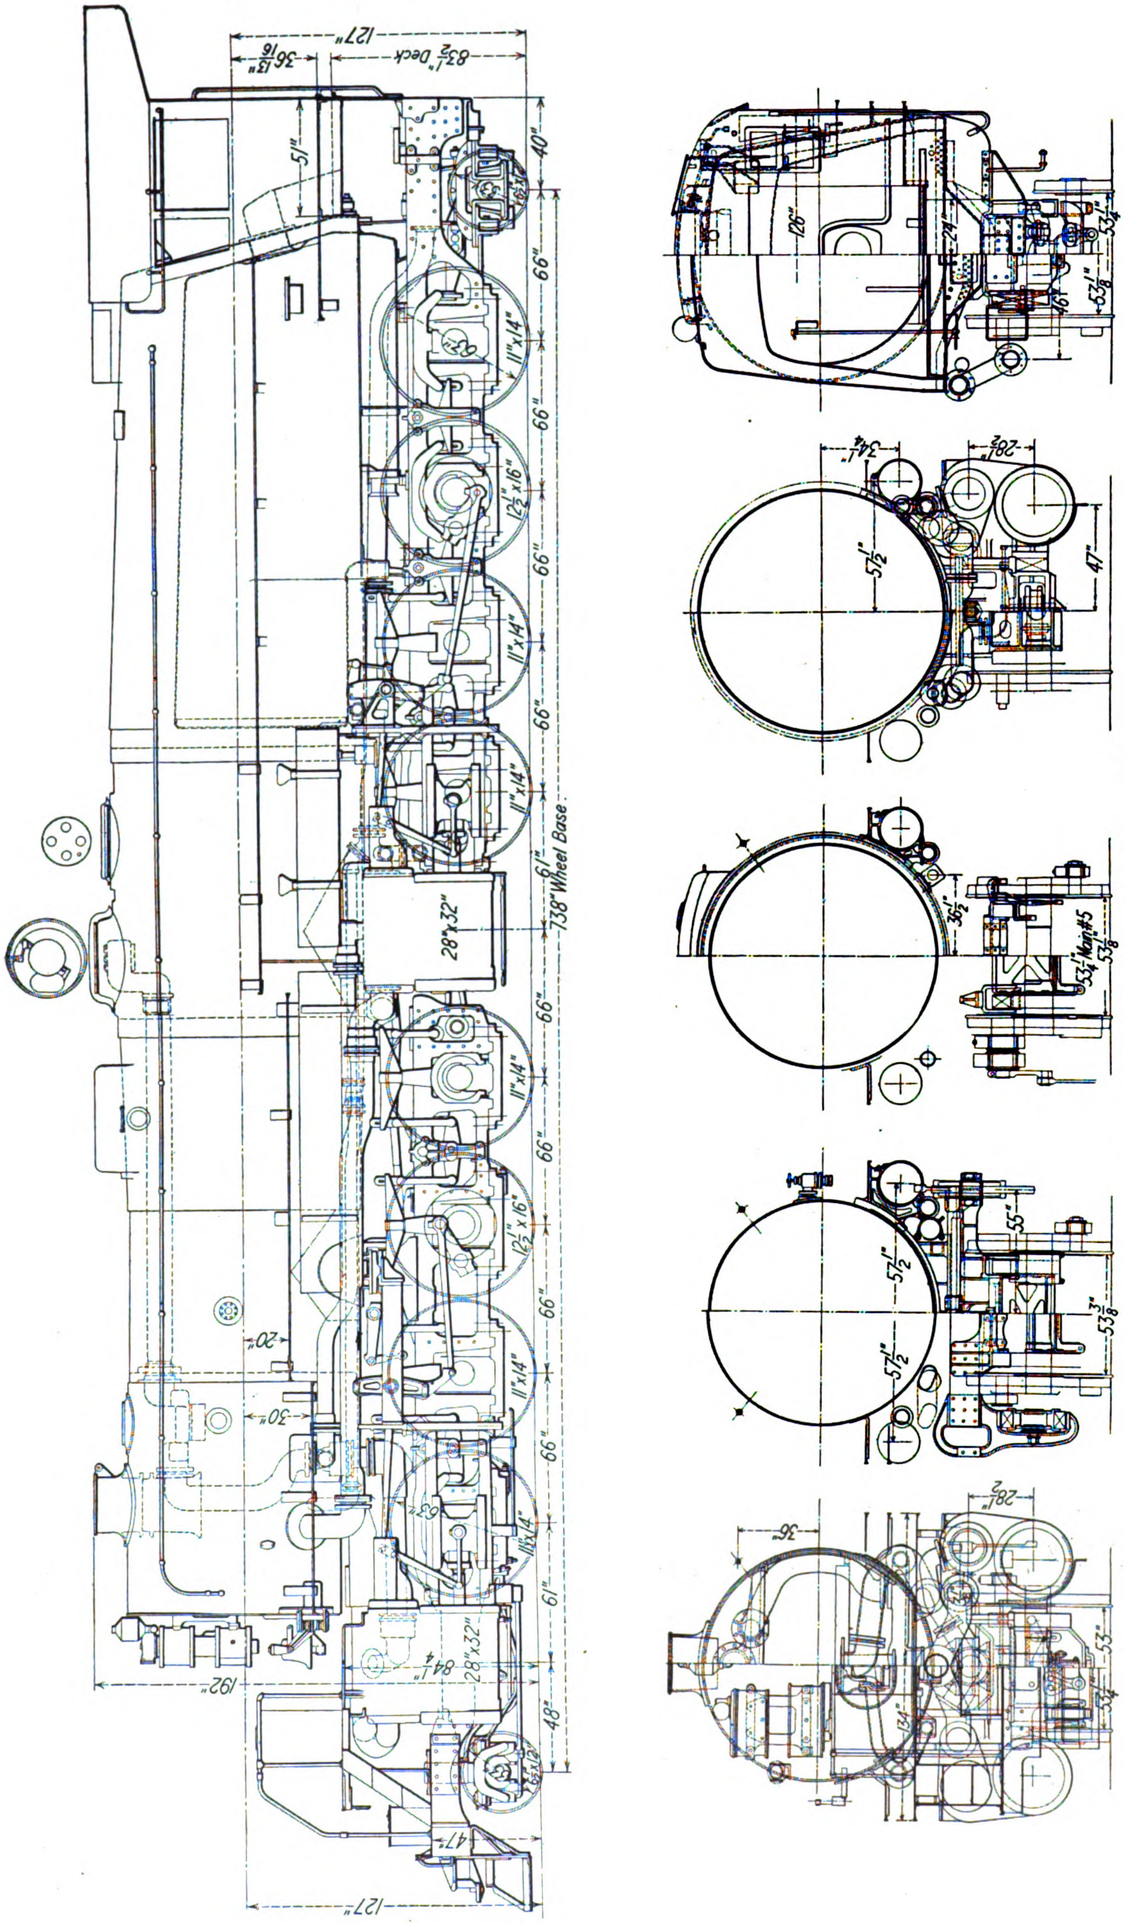
Mallet locomotives acquired by Great Northern

The Baldwin Locomotive Works, Philadelphia, Pa., recently delivered to the Great Northern four articulated locomotives of the 2-8-8-2 type. These locomotives, designated by the Great Northern as Class R-1-S, are intended for operation between Cut Bank and Whitefish, Montana, a distance of 128 miles, where the line crosses the continental divide. The ruling grade approaching the summit west-bound is one per cent, while east-bound it is 0.8 per cent with a pusher grade of 1.8 per cent, 13.8 miles long. The elevation at the summit is 5,211 ft. The sharpest curves on this section of the line are of 10 deg. although the locomotives are designed to traverse curves as sharp as 20 deg.

Since the latter part of 1923, the heavy freight traffic on this division has been handled principally by locomotives of the 2-10-2 type, which were built by the Baldwin Locomotive Works. These locomotives develop a tractive force of 87,100 lb. Four of them, which are equipped with boosters, giving a maximum starting tractive force of nearly 100,000 lb., are used as pushers on the 1.8 per



Great Northern Articulated locomotive which weighs, with tender, 916,500 lb. and develops a tractive force of 127,500 lb.



Elevation and cross-section of Great Northern Mallet locomotive

cent grade. As compared with the road engines of the 2-10-2 type, the new articulated locomotives show an increase in tractive force of nearly 47 per cent.

The largest articulated locomotives heretofore used by the Great Northern are the 25 Mallet compounds of the 2-8-8-0 type, known as Class N-1, which were built by the Baldwin Locomotive Works in 1912. During the past year a number of these locomotives were changed to use high pressure steam in four equal sized cylinders, and the design of the new locomotives was determined after experiments had proved that a material increase in hauling capacity was thus obtained. Track conditions on the Great Northern have been much improved since the Class N-1 locomotives were constructed, and with the wheel loads now permitted it is possible to apply a boiler of sufficient capacity to insure an abundant supply of steam for the four 28-in. by 32-in. cylinders used on the Class R-1-S.

The total weight of these locomotives is 594,940 lb. of which 532,800 lb. is on the drivers, 37,550 lb. on the front truck and 24,590 lb. on the trailing truck. The diameter and stroke of the cylinders are 28-in. by 32-in.; the diameter of the driving wheels is 63 in. With 210 lb. steam pressure and 65 per cent cut-off, a tractive force of 127,500 lb. is developed.

Boiler and equipment

In accordance with the usual practice on this road, the boiler of Class R-1-S is of the Belpaire type. The barrel has a conical connection, and is 100 in. in diameter at the front end, the maximum diameter being 109 in. It is fed by one Sellers non-lifting injector placed on the left side, and by one Elesco exhaust steam injector on the right side. The combustion chamber has a length of 72 in. and the tubes are 24 ft. long. The locomotives, as built, are equipped for oil burning, but the design is so worked out that they can subsequently, if desired, be equipped to burn coal and fitted with arches and mechanical stokers. At present no arch tubes are applied, but a brick wall is placed across the throat of the combustion chamber.

Flexible staybolts are applied in the breaking zones in the sides of the firebox. Hollow stays are used in the back head and back of the brick work and there is a complete installation of flexible bolts in the firebox throat and the combustion chamber.

The main dome is on the third boiler ring, and back of it on the same ring, is a man-hole opening fitted with a depressed cover in which are mounted the whistle and the four safety valves. This arrangement was necessary in order to keep within the over-all height limit.

A throttle valve of the Baldwin balanced type is placed in the main dome, and is connected with the superheater header in the smokebox by means of an internal dry pipe. The steam pipes leading from the superheater header terminate in a second header, placed transversely in the bottom of the smokebox and having connections with two outside steam pipes which lead back to the rear cylinders. The front cylinders receive their steam supply through a centrally located pipe connected to the same header, and having three ball joints. All slip and ball joints are lubricated; oil cups are used on all the packing on the locomotive.

The exhaust from the two front cylinders is conveyed to the nozzle through a pipe placed on the center line and fitted with two ball joints lubricated with oil and one slip joint lubricated with grease. The exhaust pipe from the rear cylinders is placed on the left side and it terminates in an annular opening surrounding the exhaust nozzle of the front cylinders. The steam supply for the Elesco exhaust steam injector is taken from the exhausts of both the front and rear cylinders. This injector is placed under the cab on the right-hand side.

Frame construction and running gear

The frames are 6 in. wide and are spaced 41 in. apart transversely. Special attention has been given to the design of the articulated frame connection. The vertical hinge pin is 6 in. in diameter and is held rigid in the rear cylinder saddle, being secured from turning by a tapered fit and a heavy tapered key. The saddle is bushed and the pin is case-hardened. By holding the pin rigid the wear is taken by the bushed connecting bar, which can be easily rebushed and thus the slack between the two units can be kept at a minimum. Both the vertical and horizontal hinge pins are internally lubricated with grease, which is applied from an easily accessible outside location.

The four cylinders are cast iron and are interchangeable, as are also the front and back pistons, crossheads and connecting rods. Corresponding crank pins, wheels and axles in the front and rear units interchange also. The steam distribution is controlled by 14-in. piston valves which are operated by the Walschaerts valve gear. A Ragonnet, Type B, power reverse mechanism is applied. The reach rod connecting the front and back reverse shafts is placed on the center line of the locomotive with its joint immediately above the articulated frame connection. In this way there is practically no distortion to the movement of the forward valves when the locomotive is traversing a curve. The valves all have 1⅞ in. steam lap and no exhaust clearance and are set with a travel of 6¾ in. and a lead of 3/16 in. The cut-off, when working in full gear, is 65 per cent.

The piston heads are steel of the solid type, fitted with bull rings and packing rings of Baldwin Locomotive Works special iron. The main crank pins are of vanadium steel, hollow bored. With the exception of the front main rod stubs, solid end stubs with floating bushings are used throughout. All the pins are lubricated by means of grease.

The boiler is supported on the front frames by means of a single bearer, located to give an even weight distribution and designed to distribute the load on the frames with a minimum frame stress. A low bearing pressure per square inch is assured by the liberal bearing area provided, and the bearer is designed to permit a rocking movement of the frames without binding. No centering device is applied, experience having proved that its use is unnecessary. The upper castings of the bearer and of the rear cylinder saddle are riveted to the boiler, the liners being placed outside the shell. The forward equalization divides between the second and third pairs of drivers, thus giving a three-point suspension for the front unit.

The front and rear trucks are in many respects similar in construction and have interchangeable wheels and axles. The front truck is center bearing and the rear truck side bearing, the bolsters in each case being suspended on heart shaped links. The transverse distance between the inside faces of the truck tires is 5¾ in., while for the driving tires, it is respectively 53, 53⅜, 53¼ and 53⅛ in. for the first, second, third and fourth pairs of drivers of each group. Flanged tires are used on all the wheels.

Arrangement of the cab

The cab is located sufficiently far back to place all flexible stay-bolts outside, where they are easily accessible. To provide clear vision for the enginemen, the front cab windows are placed in specially designed brass frames which permit the glass to extend the full width of the front panels. Steam piping immediately forward of the cab is placed under the jacket; and this, together with the downward trend of the running boards as they extend forward and the arrangement of all external fittings, gives

the engine crew as clear a vision as can be obtained in a locomotive of this size and type.

These locomotives are equipped with force feed lubricators for the front cylinders, and with flange oilers on the leading drivers of both the front and back units. A drifting valve with the handle conveniently located in the cab, and having a 2½-in. pipe connection to the steam valve stand, supplies steam to the cylinders when drifting. The main steam valve stand is placed on the roof sheet in front of the cab, and there is also an auxiliary steam manifold on the left side of the back head connected to the steam valve stand and serving the blower in the smokebox, the oil atomizer, tank heater, oil heater, cab heater, sprinkler, flange lubricator heater and the force feed lubricator heater. On the right side of the back head is an air manifold, with valves serving the bell ringer, sanders, cylinder cocks for the front unit and cylinder cocks for the back unit. This manifold also has plugged connections for the fire door, tube cleaner and whistle.

The oil burning arrangement has a number of interesting features. The damper controlling the intake of air through the fire pan is automatic in its action, opening by draft and closing by gravity. The fire door is provided with an intake riser through the deck, thus preventing cold air from being drawn into the cab. The firebox has a brick flash wall in the back and all firebox seams are protected from the direct action of the fire by seam fire brick.

In order to prevent the exhaust from the air compressors from drawing on the fire when drifting down long grades, the compressors discharge into a separate header, which provides an atmosphere exhaust.

The tender of this locomotive is carried on two Commonwealth cast steel trucks of the six-wheeled equalized type. The frame is a one-piece, Commonwealth steel casting. The tender is built with a stoker conveyor trough, in view of possibly changing to coal burning in the future. A pilot is placed at the rear end. With a capacity for 16,800 gal. of water and 5,800 gal. of oil, these tenders rank among the largest thus far built.

These locomotives have a height over all of 16 ft. 1 in. and a maximum width of 11 ft. 3 in. The length measured from the face of the engine front bumper to that of the tender rear bumper is 104 ft. 4 in. Further particulars concerning dimensions, weights and proportions are given in the following table:

Railroad	Great Northern
Type of locomotive	2-8-8-2
Service	Freight
Cylinders, diameter and stroke	4-28 in. by 32 in.
Valve gear, type	Walschaert
Valves, piston type, size	14 in.
Maximum travel	6¾ in.
Outside lap	1⅛ in.
Exhaust clearance	None
Lead in full gear	3/16 in.
Cut-off in full gear, per cent	65
Weights in working order:	
On drivers	532,800 lb.
On front truck	37,550 lb.
On trailing truck	24,590 lb.
Total engine	594,940 lb.
Tender	321,560 lb.
Wheel bases:	
Driving	43 ft. 7 in.
Rigid	16 ft. 6 in.
Total engine	58 ft. 2 in.
Total engine and tender	96 ft. 3½ in.
Wheels, diameter outside tires:	
Driving	outside, 63 in; center, 56 in.
Front truck	33 in.
Trailing truck	33 in.
Journals, diameter and length:	
Driving, main	12½ in. by 16 in.
Driving, others	11 in. by 14 in.
Front truck	6½ in. by 12 in.
Trailing truck	6½ in. by 12 in.
Boiler:	
Type	Belpaire
Steam pressure	210 in.
Fuel, kind	Oil
Diameter, first ring, inside	109 in.
Firebox, length and width	144 in. by 108 in.
Arch tubes, number and diameter	None
Combustion chamber length	72 in.
Tubes, number and diameter	310, 2¼ in.
Flues, number and diameter	68, 5½ in.
Length over tube sheets	24 ft.
Grate area	108 sq. ft.
Heating surfaces:	
Firebox and comb. chamber	432 sq. ft.
Tubes and flues	6,710 sq. ft.
Total evaporative	7,142 sq. ft.
Superheating	1,896 sq. ft.
Comb. evaporative and superheating	9,038 sq. ft.
Special equipment:	
Brick arch	No
Superheater	Yes
Feedwater heater	Yes
Stoker	No
Booster	No
Tender:	
Style	Cylindrical
Water capacity	16,800 gal.
Fuel capacity, oil	5,800 gal.
General data estimated:	
Rated tractive force, 65 per cent	127,500 lb.
Weight proportions:	
Weight on drivers ÷ total weight engine, per cent	89.5
Weight on drivers ÷ tractive force	4.09
Total weight engine ÷ comb. heat. surface	65.7
Boiler proportions:	
Tractive force ÷ comb. heat. surface	14.10
Firebox heat. surface ÷ grate area	4.00
Firebox heat. surface, per cent of evap. heat. surface	6.04
Superheat. surface, per cent of evap. heat. surface	26.5

Report on grates with restricted air openings*

THE Committee on Front Ends, Grates and Ash Pans agreed to limit its report to the results of experiments on the use of restricted air openings in grates, which it had learned were in progress on two western railroads. At this time it is to give only a general statement of the purposes of these tests and some general observations on the results thus far obtained.

On one of the roads referred to, the use of grates with restricted air openings was apparently undertaken primarily because of loss of coal through the grates. This with friable coal which does not soften and coalesce on the grates may assume serious proportions. On the other road the restricted air openings were first used in locomotives burning lignite, and the practice was resorted to chiefly because of the difficulty of maintaining the fire bed in good condition with grates of the ordinary design. It appears therefore, that in both cases restricted air openings in grates have been used largely because the coal to be burned was in some respects unusual, and the committee is of the opinion that such a practice will be justified only under special conditions and that it is not likely to become widespread.

The committee believes that for the majority of railroads and for most of the coals in use the aggregate air opening in grates should continue to be made as great as the circumstances permit. With this understanding we are glad to submit the following statements concerning the practice of restricting the grate openings.

With reference to its experiments the first of the two roads referred to makes the following statement: "We have done a great deal of experimenting with different designs of table grates compared with the standard finger grates such as are ordinarily used in locomotives. We went into this experimental work on account of the waste, due to fuel falling through the finger grate in an unburned or partially burned condition."

The remainder of the statement from this road quoted by the committee may be summarized as follows: Smokebox gas analyses made with the different table grates indicated that there was still four or five per cent of free oxygen in the flue gases so that it seemed feasible to continue to decrease the size of grate openings until the effective air opening had been reduced to about 16 per cent of the total grate area, with ¾-in. circular air open-

*Abstract of report and discussion read at the seventeenth annual convention of the International Railway Fuel Association at Chicago, May 26-29.

ings, tapering to 1 1/16 in. at the bottom of the grate bar. This grate has been found to increase materially the carbon dioxide and to reduce the free oxygen. This road states that tests indicate a saving of about six per cent as compared with finger grates.

The other road referred to is the Northern Pacific. The report quotes a letter from M. A. Daly, general fuel supervisor, with respect to experience in burning Rosebud (lignite) coal mined in Montana. This coal as fired has the following analysis:

Moisture	25.66 per cent
Volatile	28.39 per cent
Fixed carbon	38.59 per cent
Ash	7.36 per cent
Heating value	8,743 B.t.u.

This coal breaks up in burning and is very difficult to keep on the grate, the strong draft lifting it and uncovering thin spots in the fire, when using grates with ¾-in. slotted openings. The grate now used has circular openings ½ in. in diameter at the top and ⅞ in. in diameter at the bottom and gives air openings from 12 to 13½ per cent of the area of the bar, and a few per cent greater air opening when measured in relation to the total grate area. It has been found that these grates also burn such coals as Pittsburgh No. 8 from Ohio and other bituminous coals satisfactorily, as well as the lignite for which they were particularly designed, and slightly increased efficiency is expected from this grate burning these coals when accurate tests are made.

The committee states that Mr. Daly is of the opinion that the success of these grates is not to be ascribed to the reduction in the aggregate air opening, but primarily to the size of the holes through the grate which reduce the force of the jets of air drawn through the grates so that they do not disturb the particles of coal on the grate when the locomotive is working.

The report is signed by Edward C. Schmidt (University of Illinois), Chairman, M. C. M. Hatch (M. K. T.), V. L. Jones (N. Y., N. H & H.), G. H. Likert (U. P.), John P. Neff (American Arch Company), C. B. Smith (B. & M.), F. C. Thayer (Southern), G. A. Young (Purdue University) and F. Zeleny (C. B. & Q).

Discussion

This report led to a lively discussion in which there was considerable disagreement as to the fundamental soundness of going to the restricted air openings described. In the experience of the Atchison, Topeka & Santa Fe with the restricted air openings described, the important points apparently are the saving through the elimination of fire dropping into the ash pan, which formerly required cleaning three or four times over a division, and the ability to maintain a light even fire. The experience on this road has led its officers to believe that sufficient air enters the firebox through the restricted grate openings to maintain satisfactory combustion. It was stated that a saving of about 6 per cent in fuel per unit of work has been observed, although this is not the result of elaborate tests.

Considerable skepticism was voiced as to the combustion efficiency obtained with the grates having the highly restricted air openings, the discussion suggesting that the restricted openings have effected their savings by stopping a heavy loss through the grates rather than by improving combustion conditions.

The evaporative capacity of locomotive boilers

Factors determining the coefficients of the proposed formula—A practical application

By Alexander P. Poperev

Part II

WE have started from an assumption that the evaporative capacity of the locomotive boiler is determined by three factors; namely, the design of the boiler, the kind of fuel and the rate of combustion. Formula (6) shows how the evaporative capacity varies with the rate of combustion, and it remains now to tie up this formula with two other factors, namely, the design of the boiler and the kind of fuel used. In other words, our present problem will be to determine the values of the coefficients in formula (6) for any given boiler and fuel.

The complexity of this problem and the difficulties connected with it can be readily appreciated, particularly if we take into account the great variety of fuels used as well as variations in the design of boilers, on the one hand, and the scarcity of suitable experimental data, which can be used for this purpose, on the other. The latter consideration presented most of the difficulties and proved to be the greatest obstacle in extending the scope of the present work.

The method, adopted by the writer for attacking this problem, was as follows: Inspection of experimental data suitable for our purpose on the evaporative performance of the locomotive boiler has shown that while they referred to a great variety of locomotive boilers, there were only two kinds of fuel used, each of fairly uniform quality. Accordingly, all the available data were segregated into two groups, according to the fuel used. This enabled us to eliminate one variable factor, the fuel, and to analyze the effect of the design of a boiler on its evaporative performance. For this purpose the values of the equivalent rate of evaporation for every locomotive in each group were plotted against corresponding rates of combustion, and the equation of a representative curve, which would agree well with the experimental data and yet satisfy formula (6) was then determined. Thus the values of the coefficients a, b and c of formula (6) were obtained for every locomotive. As the fuel in each group of data was, for all practical purposes, of the same quality, the values of the coefficients of formula (6) for each

group could be considered in accordance with our assumption as being dependent on only one variable; namely, the design of the boiler.

In order to determine the factor representing the effect of the boiler design, the obtained values of the coefficients of formula (6) were plotted against different boiler ratios. After a number of trials it was found that a smooth curve was obtained only when the values of the coefficients were plotted against the ratio,

$$R = \frac{\text{Heating surface}}{\text{Grate area}}$$

showing thereby the existence of a definite relationship between these quantities. Therefore, this ratio has been chosen as a factor representing the effect of boiler design. This should not be entirely unexpected, if we recall that the coefficients of formula (6), as it was shown above, actually represent various heat losses in the boiler expressed in terms of the equivalent rate of evaporation. From general considerations and partly from experiment we know that there exists a certain proportionality between various heat losses and the ratio R, as naturally the heat in the boiler will be utilized the better, the greater will be the amount of heating surface with respect to the grate area and vice versa.

As some of the locomotives used in the tests had a superheater, the question arose, what value of heating surface has to be taken in the determination of the ratio R. There is no fixed relation between the evaporating and superheating surfaces and as the problem concerned primarily the determination of evaporative capacity of the locomotive boiler, with all the simplification possible, it suggested itself to determine the ratio R as

$$R = \frac{\text{evaporating heating surface (excluding superheater)}}{\text{grate area}}$$

in all cases, irrespective of whether there was a superheater or not. The trials showed, that in this way the difficulty due to the presence of the superheater could be obviated, provided that the corresponding values of the equivalent rate of evaporation are calculated on the basis of heat transferred through the evaporating heating surface only; in other words, as if the boiler had no superheater at all. Accordingly, only these values of the equivalent rate of evaporation were used, and they were denoted by Z_e, in order to distinguish them from values which are usually calculated on the basis of total heat in a pound of steam.

Once a proper factor representing the effect of the design of the boiler was established, there was little difficulty in finding an empirical equation for the relationship between the values of the coefficients in formula (6) and the ratio R. In the course of determining these equations, it has been found that boilers equipped with arches have to be segregated in a separate group, as the presence of the arch produces a marked effect on the proportion of the various heat losses. Finally all available experimental data were classified into the following groups:

1—Bituminous coal.
 a—Boilers, with arch.
 b—Boilers, without arch.
2—Semibituminous coal.
 a—Boilers, with arch.
 b—Boilers, without arch.

Unfortunately, the available experimental data referring to tests with semibituminous coal and boilers without the arch were not sufficiently complete and as a result, the corresponding equations for this group were not determined. The dimensions of the boilers, the fuel used and the references from which the corresponding experimental data used for the determination of these equations were taken are listed in Table I. It is shown in this table that the ratio R varies from 33.29 up to 79.56, which covers the entire range used in practice.

The results obtained—Values of the coefficients of formula (6) and their equations

The physical significance of the coefficient a is, as it has been shown, a heat loss due to radiation, leaks, etc.,

expressed in terms of the equivalent rate of evaporation. This kind of loss is naturally totally independent of the kind of fuel used and being calculated per unit of heating surface of a boiler, may be considered without any serious error as constant for all designs of locomotive boilers. The actual values of coefficient *a* obtained for different locomotives varied but little from each other and an average value of 0.4 was accepted as a representative value of this coefficient for any boiler or fuel. It is interesting to note, that according to Dr. Goss's[1] experiments with stationary locomotive boilers, the total heat loss at the beginning of cooling off was equal to 273,000 B.t.u. per hour, which in terms of equivalent rate of evaporation amounted to 0.231 lb. per sq. ft. per hour. During motion the average heat loss amounted to 6,000 B.t.u. per minute or 0.305 lb. per sq. ft. per hour in terms of equivalent evaporation. In other words, the value obtained for the coefficient *a* comes very near to the experimental data.

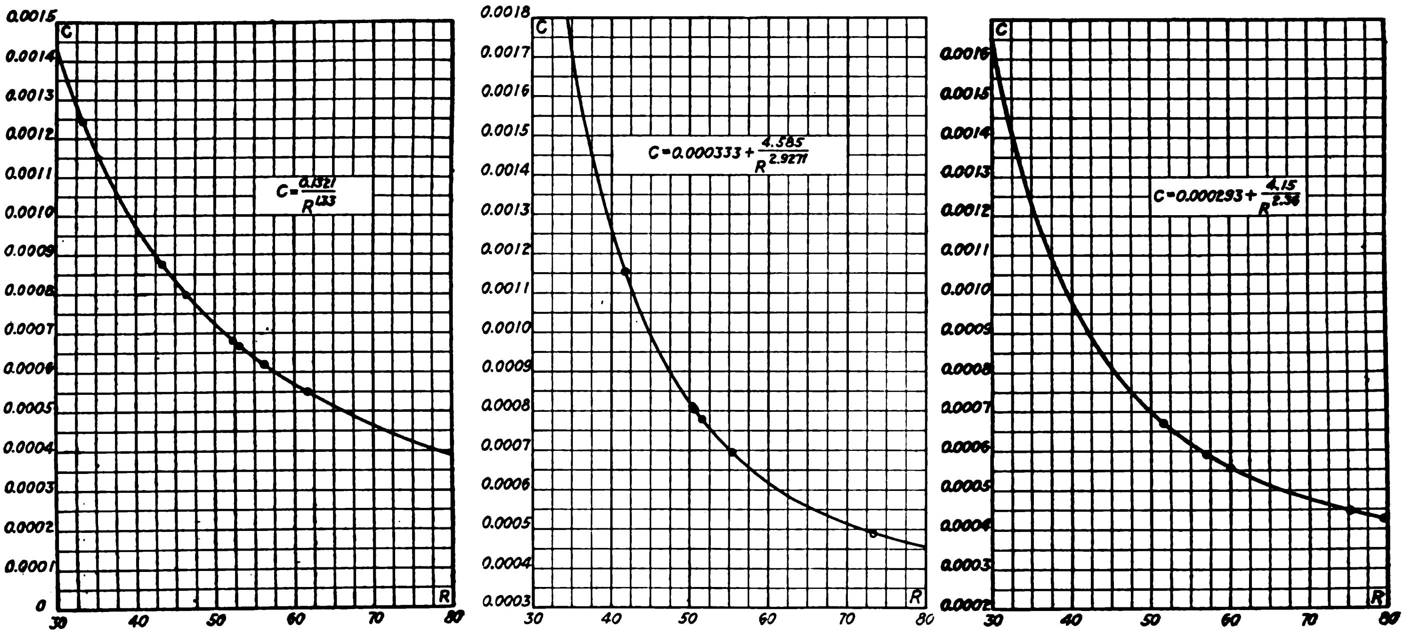

Fig. 1—Charts showing values of coefficient C.—The left is for bituminous coal and boilers having an arch; two others for semi-bituminous coal; center—for boilers without an arch; right—for boilers having an arch

It has been shown[2], that the coefficient *b* of formula (6) can be considered as consisting of two terms;

$$b = \frac{KG}{Hr} - n = \frac{K}{Rr} - n,$$

of which the first represents the theoretical value of the rate of evaporation, corresponding to the rate of combustion equal unity, and the second term, *n*, represents a certain summary loss, directly proportional to the rate of combustion. It is the relationship between this heat loss and the size and type of the boiler that we are interested in establishing because the value of $\frac{K}{Rr}$ can always be easily calculated for any given boiler and fuel. Accordingly, values of *n* were determined (from found values of coefficient *b*) for every locomotive in each group and plotted against corresponding values of *R*. The following relationships were thus established:

[1]Locomotive Performance, by Dr. W. F. Goss, pp. 186, 216.
[2]August, 1924, *Railway Mechanical Engineer*, p. 491.

Bituminous coal—for boilers having an arch:

$$(7) \quad \dots\dots\dots \quad n = \frac{0.3294}{e^{0.0363R}}$$

Semi-bituminous coal for boilers having an arch:

$$(8) \quad \dots\dots\dots \quad n = \frac{0.08368}{e^{0.00679R}}$$

Semi-bituminous coal—for boilers without an arch:

$$(9) \quad \dots\dots\dots \quad n = \frac{7.0}{R^{1.173}}$$

In equations (7) and (8), *e* is the base of the natural logarithms. Knowing the value of *n*, the value of the coefficient *b* can be calculated very easily.

The following expressions have been found to express the relationship between the values of the coefficient *c* and the ratio *R*:

Bituminous coal—for boilers having an arch:

$$(10) \quad \dots\dots\dots \quad c = \frac{0.1321}{R^{1.33}}$$

Semibituminous coal—for boilers having an arch:

$$(11) \quad \dots\dots\dots \quad c = 0.000293 + \frac{4.15}{R^{2.36}}$$

Semibituminous coal—for boilers without an arch:

$$(12) \quad \dots\dots\dots \quad c = 0.000333 + \frac{4.585}{R^{2.9271}}$$

Graphs of the above expression are shown in Figs. 1, 2 and 3.

Resulting equations for the evaporative capacity of the locomotive boiler

The resulting equations for the evaporative capacity of the locomotive boiler for different conditions can thus be presented as follows:

Bituminous coal—for boilers having an arch:

$$(13) \quad \dots\dots \quad Z_e = -0.4 + \left(\frac{K}{Rr} - \frac{0.3294}{e^{0.0363}R}\right) Y - \frac{0.1321}{R^{1.33}} Y^2$$

Semibituminous coal—for boilers having an arch:

$$(14) \quad . \quad Z_e = -0.4 + \left(\frac{K}{Rr} - \frac{0.08368}{e^{0.00679}R}\right) Y - \left(0.000293 + \frac{4.15}{R^{2.36}}\right) Y^2$$

Semibituminous coal—for boilers without an arch:

$$(15) \quad . \quad Z_e = -0.4 + \left(\frac{K}{Rr} - \frac{7.0}{R^{1.173}}\right) Y - \left(0.000333 + \frac{4.585}{R^{2.9271}}\right) Y^2$$

In all the above formulas:

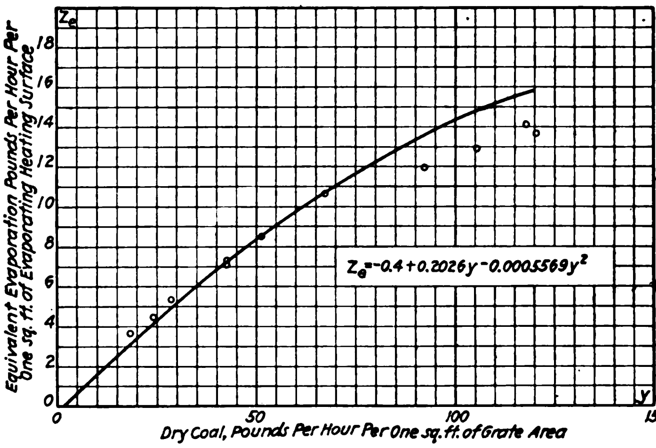
Z_e = the equivalent rate of evaporation, from and at 212 deg. F., of wet steam in lb. per sq. ft. of evaporative heating surface (excluding the superheater) per hour.
Y = the rate of combustion in pounds of dry coal per sq. ft. of grate area, per hour.
R = the ratio of evaporating heating surface (excluding the superheater) to grate area.
r = the heat of vaporization from and at 212 deg. F.
K = the heating value of 1 lb. of dry fuel in B.t.u.
e = 2.7183, the base of the natural logarithms.

One must not, of course, consider the above expressions as exact or final; the experimental data on which they are based were none too numerous and like every empirical equation, they are subject to corrections with the further accumulation of experimental data, particularly in the values of the coefficients. However, in nearly all of the nineteen locomotives which were analyzed and enumerated in Table I, they come to a rather surprising close agreement with experimental data. Lack of space prevents the showing of plots for every locomotive. Those, which are shown here, as well as in Part I of this article are fairly representative for the large majority of the plots. Only in very few cases was there a disagreement which did not exceed 15 per cent between the values determined by the above formulas, values obtained from experiment. The disagreement manifested itself however mostly at rather high rates of combustion. Considering this we must have in view a few cases, taken from the Pennsylvania tests, in which attention has been called to the fact, that there was noticed at the higher rates of combustion an insufficient air supply, and the evaporation was below normal; besides, the experimental data per se are hardly more accurate, at the best, than within 10 or 15 per cent.

It is believed, however, that even with this inaccuracy the suggested expressions will be found useful in ordinary influence of this factor in the formulas. The experiments must be complete to obtain definite results.

Diagram for the evaporative capacity of the locomotive boiler

Despite every attempt to simplify the problem as much as possible, the resulting expressions obtained are too



Curve showing the evaporative capacity of the Vauclain four-cylinder compound No. 535—Boiler dimensions and kind of fuel used is shown in Table I

complicated to be conveniently used in practice. However, a diagram, embodying these expressions can be easily constructed, by means of which all necessary calculations can be performed in the most simple manner.

The diagram, shown in Fig. 4, consists of four

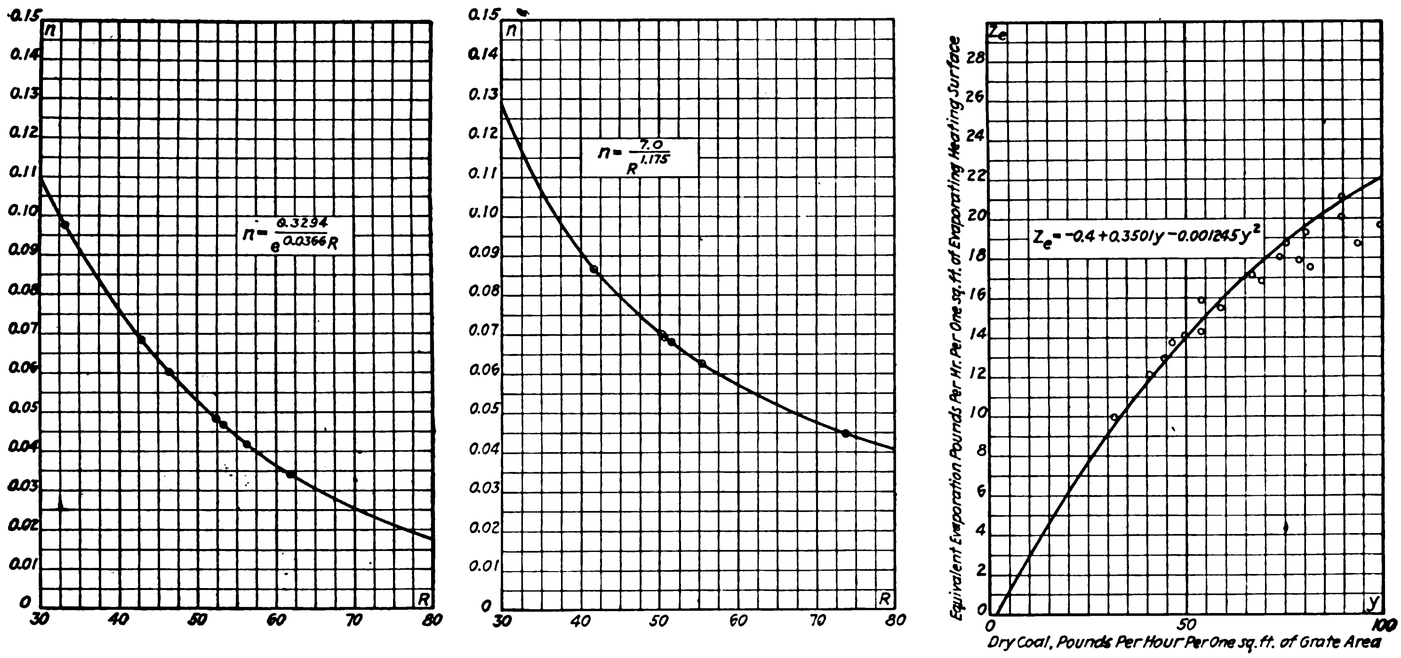


Fig. 2—First two charts show values of coefficient n: Left—for bituminous coal and boilers having an arch; Center—for semi-bituminous coal and boilers without an arch. Right—Curve showing evaporative capacity of Pennsylvania locomotive No. 318, class E 3S D

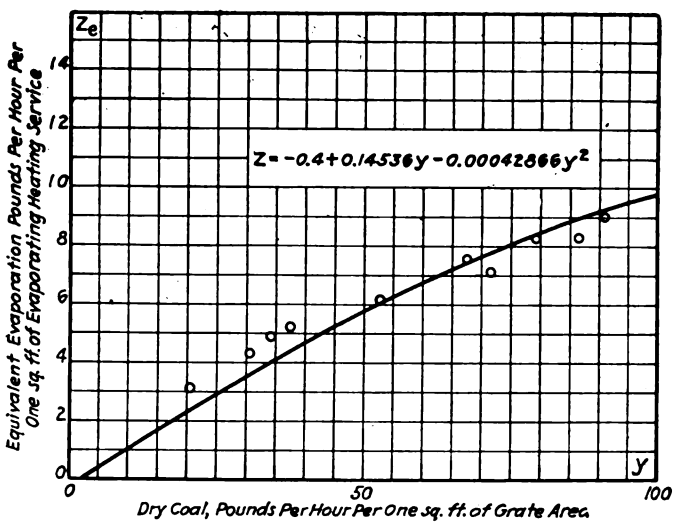
practice, as they permit one to estimate the probable evaporative capacity of the locomotive boiler with greater accuracy than with any of the other existing formulas. No doubt, with the accumulation of experimental data it will be found possible to increase the accuracy still more, particularly when experiments with a greater variety of fuels would permit one more accurately to account for the quadrants. In the upper right quadrant the values of the coefficient $b = \dfrac{K}{Rr} - n$ for different values of K are plotted as ordinates against corresponding values of R as abscissae. Now for any given value of y the quantity by, which represents the second term in formula (6), can be represented by a straight line, when referred to

*See the *Railway Mechanical Engineer* for August, 1925, page 491.

the co-ordinate axes O-B and O-P. Such lines are plotted in the upper left quadrant for different values of y, from $y = 10$ lb. per sq. ft. up to $y = 150$ lb. per sq. ft., and the result is read off on the axis O-P. In the lower right quadrant are plotted as ordinates the values of the coefficient c of the formula (6) against corresponding values of R as abscissae. Again, for every given value of y, the expression $a + cy^2$ being referred to the co-ordinate axes O-C and O-Q can be represented by a straight line. These lines are drawn in the lower left quadrant, likewise for different values of y, from $y = 10$ lb. per sq. ft. up to $y = 150$ lb. per sq. ft., and the result is read off on the axis O-Q, which, for convenience, has a double scale compared with that of the axis O-P. Thus, the construction of the diagram does not present any difficulties, particularly if we remember that for the construction of every straight line in both the left hand quadrants, it is necessary to calculate only two values of the corresponding expressions by and $-(a + cy^2)$.

The method of using the diagram will be clear from the following example. Suppose we want to find the value of Z_e for $y = 100$ lb. per sq. ft. for a boiler having an arch and having the ratio $R = \frac{H_e}{G} = \frac{3676.1}{70.03} = 52.49$, the fuel being bituminous coal having a heating value of 14,140 B.t.u. per pound of dry coal. On the axis O-R we read of the value $R = 52.49$ and from this point follow up vertically to the intersecting point q with a curve in the upper quadrant, corresponding to the heating value for the coal of 14,140 B.t.u. From this point we proceed parallel to the axis of abscissae until we intersect the straight line in the upper left hand quadrant corresponding to $y = 100$ lb. per sq. ft. at the point s. On the axis O-P we read of the value of by equal to, say, 23.0.



Curve showing the evaporative capacity of a cross-compound consolidation locomotive, shown in Table I as No. 585

Starting again from the point t on the axis O-R and proceeding this time downward, parallel to the axis of ordinates, up to the intersection point u on the curve C, and from it horizontally up to the intersection (point v) with the straight line in the lower left hand quadrant corresponding to $y = 100$ lb. per sq. ft., we read on the axis O-Q a value, say 7.2. By subtracting it from the value found before we obtain a value for Z_e corresponding to $y = 100$ lb. per sq. ft.

$$Z_e = 23.0 - 7.2 = 15.8 \text{ lb. per sq. ft. per hour.}$$

Obviously, the same simple procedure applies to finding the value Z_e for any value of y.

Other relationships derived from formula (6)

While the relationship between the rate of evaporation and the rate of combustion represents a basic relationship which fully characterizes the performance of a boiler, it is desirable sometimes to know how other factors—for instance, the efficiency of the boiler, or rate of evaporation per pound of fuel—vary with the rate of combustion. It can be easily shown that once the relationship between the rate of evaporation and the rate of combustion is established for any given conditions, all these relationships can be very easily derived from the formula (6). As an example we shall consider here the derivation of the formulas for the relationship between the rate of combustion and the efficiency of the boiler, as well as the rate of evaporation per pound of fuel.

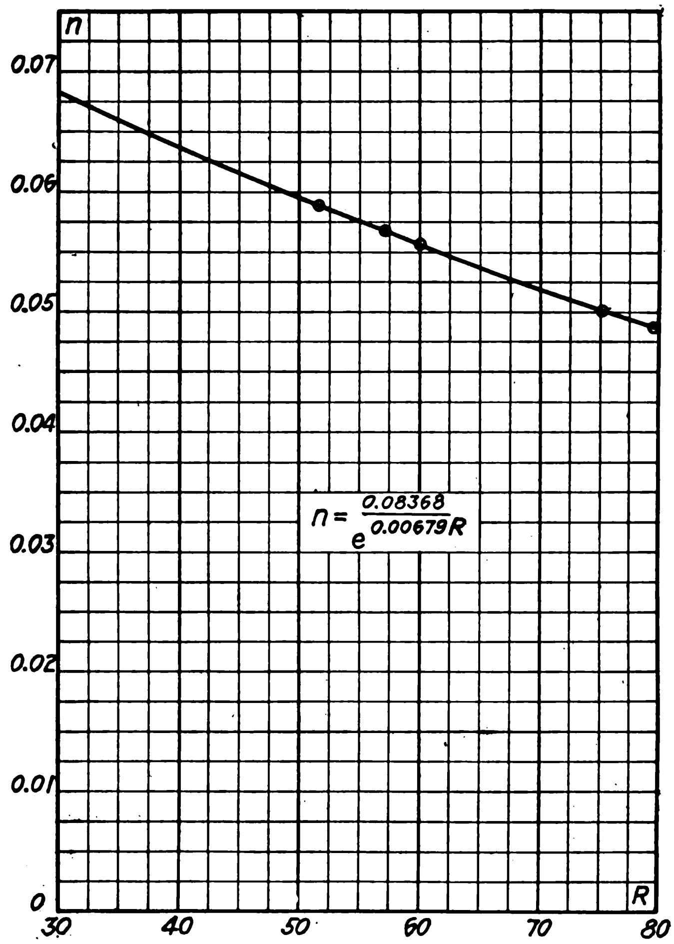


Fig. 3—Curve showing the values of the coefficient *n* for semi-bituminous coal and boilers having an arch

From the general definition of the efficiency of the boiler

$$\text{Eff.} = \frac{\text{Heat utilized}}{\text{Heat consumed}}$$

and using the same notations for the heating surface, grate area, rates of evaporation and combustion as above, we have

$$(16) \qquad \text{Eff.} = \frac{HZr}{KGy}$$

substituting in equation (16) the expression for Z according to formula (6) we have

$$\text{Eff.} = \frac{Hr}{KG}\left(\frac{-a + by - cy^2}{y}\right)$$

$$= \frac{Hr}{KG}\left(-\frac{a}{y} + b - cy\right)$$

For any given boiler and fuel the factor $\frac{Hr}{KG} = \frac{Rr}{K}$ is constant and therefore we can write

$$\text{(17)} \quad \text{Eff.} = -\frac{p}{y} + q - sy$$

where $p = \frac{Hr}{KG} a$; $q = \frac{Hr}{KG} b$, and $s = \frac{Hr}{KG} c$ are constants for a given boiler and fuel.

$$\text{(18)} \quad y_{\text{max. eff.}} = \sqrt{\frac{p}{s}}$$

Substituting this in (17) we obtain the maximum value of the efficiency of the boiler as

$$\text{(19)} \quad \text{Eff.}_{\text{max.}} = q - 2\sqrt{ps}$$

From formula (6) it is also very easy to derive, in the same way as above, an expression for the relationship between the rate of evaporation per pound of fuel and the rate of combustion. The rate of evaporation per

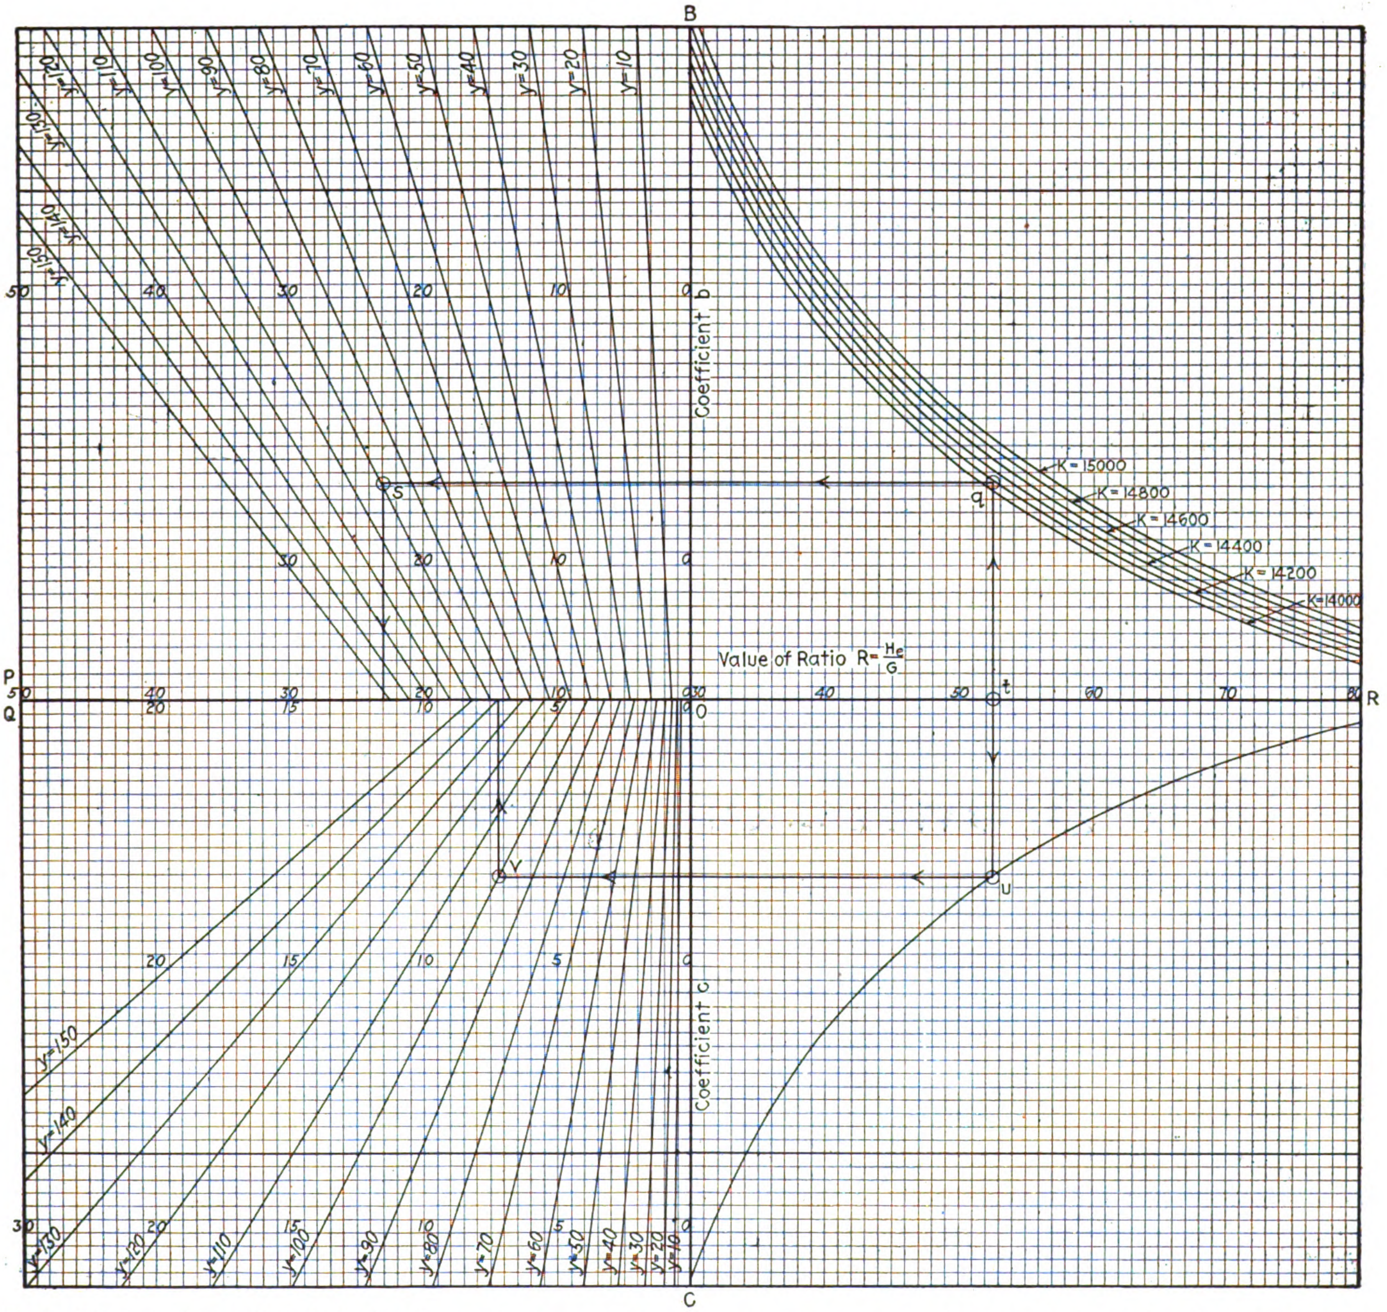

Fig. 4—Diagram for use in calculating the evaporative capacity of locomotive boilers having an arch and fired with bituminous coal

The formula (17) represents the expression of the relationship between the efficiency of a boiler and the rate of combustion and is the equation of a hyperbola. It permits us to determine the maximum value of the efficiency of the boiler, as well as the rate of combustion at which it occurs.

By differentiating formula (17) we obtain the value of the rate of combustion corresponding to a maximum value of the efficiency of the boiler

pound of fuel evidently can be expressed in the following way

$$\text{(20)} \quad f = \frac{ZH}{Gy} = \frac{ZR}{y}$$

Substituting the expression for Z from formula (6), we have

$$f = \frac{ZR}{y} = \frac{(-a + by - cy^2)R}{y}$$

and as $R = \frac{H}{G}$ is constant for a given boiler and fuel, we have

$$f = \frac{-aR}{y} + bR - cRy =$$

$$(21) \quad = -\frac{m}{y} + t - vy$$

where

$$m = aR;\ t = bR, \text{ and } v = cR$$

are constants for a given boiler and fuel.

The maximum value of the rate of evaporation per

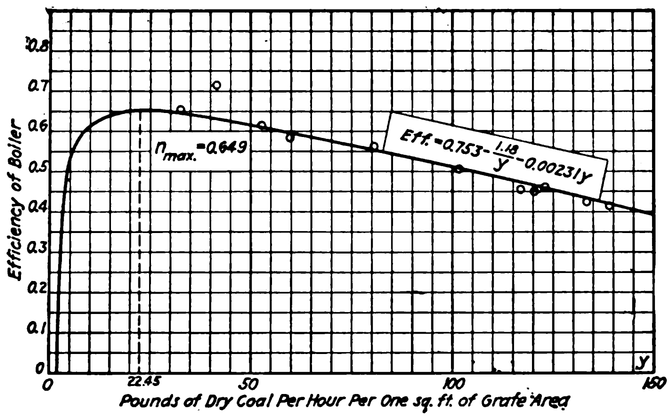

Fig. 5—Curve showing the relationship between the boiler efficiency and rate of combustion—Data taken from Pennsylvania R. R. Tests

pound of fuel will be found in a similar manner as follows:

$$(22) \quad f_{max.} = t - 2\sqrt{mv}$$

and the corresponding rate of combustion

$$(23) \quad y \text{ f equals max.} = \sqrt{\frac{m}{u}}$$

Figs. 5 and 6 illustrate the application of the above expressions to experimental data. As it can be seen from the plots, the maximum of both the efficiency and the rate of evaporation per pound of fuel occurs at rather low rates of combustion, which are not only outside of

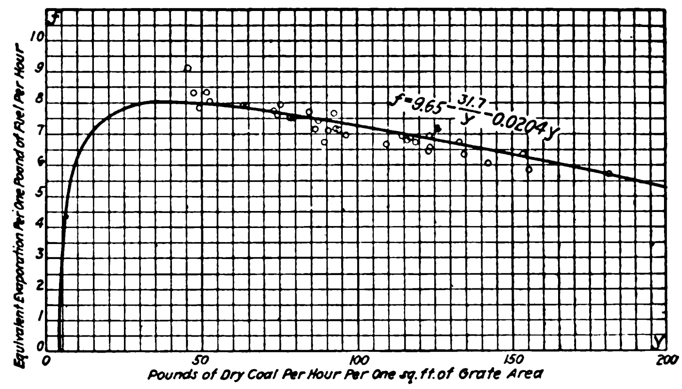

Fig. 6—Curve showing the relationship between the rate of evaporation per pound of fuel and the rate of combustion—Data taken from Dr. Goss' tests

the usual service range, but also usually outside of the experimental range. To this fact can be attributed many wrong conclusions in regard to the nature of these relationship between the rate of evaporation and the rate of combustion. On the contrary, by applying the same analysis to expressions (17) and (21), we fail to find any similar contradictions, which fact can be considered as an additional proof that the basic expression (6), from which these formulas are derived, is correct.

"Bill Brown" or "Top Sergeant" —which?

Our readers, judging from the letters to the editor, are taking a keen interest in this controversy

NATURALLY there are a great many differences of opinion as to the duties and responsibilities of foremen and supervisory officers. The first prize article in the *Railway Mechanical Engineer* competition on the opportunities and responsibilities of the foreman, written by "Bill Brown" was published in the June *Railway Mechanical Engineer;* three communications concerning it appeared in the August number, page 492. Two of the writers backed up "Bill Brown" and enlarged upon some of his suggestions. "Top Sergeant," however, drastically criticized him.

Shortly after the distribution of the August number we began to receive communications, the first three more or less unreservedly backing up "Bill Brown" and taking issue with "Top Sergeant." The fact that these letters came from such widely scattered sections as Michigan, Texas and Ohio made it look as if there was nothing to the controversy and that "Bill Brown" would walk away with all the honors. Later mails, however, brought letters of a very different sort, either strongly supporting the position of "Top Sergeant" or criticizing "Bill Brown." A selection from these communications follows. Which side do you agree with?

"Top Sergeant" a supreme egotist

Galveston, Tex.

To the editor:

The letter on page 492 of your August issue may perhaps be somewhat of a surprise to those higher railway officers who may chance to read it.

It is not often that a person of the calibre of "Top Sergeant" has either the intelligence or the audacity to set down his candid opinions in black and white. Unfortunately, however, his kind are only too numerous in minor supervisory positions in the railway service, and his remarks should be earnestly recommended to the careful perusal and consideration of those executives who are constantly bewailing the lack of "loyalty and co-operation" on the part of their employees.

"Top Sergeant" betrays his supreme egotism in his

attitude toward the railway trade journals, although he seems able to spare sufficient of his valuable time to keep posted on the work of his favorite cartoonists. In view of his extraordinary complete knowledge of railway mechanical engineering, one wonders why he chooses to remain in a subordinate position rather than engage in more remunerative consulting practice where he will have sufficient time to study and read literature that will tend to broaden his mind and dispel his pessimistic views of his fellowmen.

Were it not for the fact that he is deadly earnest, "Top Sergeant's" letter, which is but the pathetic effusion of a small and reactionary mind, would deserve a position on the humorous page.

An ex-apprentice boy,
Alfred M. Hallington.

The foreman—a superman?

Railroad Shop.

To the editor:

"Bill Brown," the author of the prize article on "The Foreman and His Responsibility" is surely an optimist and has kidded himself into looking at the bright side of the picture. Your editorial in the June number indicated that he was a successful shop superintendent. I wonder whether his position is not such that he is too far above the department foremen and does not understand all of the difficulties that they are up against in these days.

I have been a foreman in the machine shop for many years. Twenty years ago we did not have any of these high-fangled notions about dealing with the men and we managed to get along pretty well. I have 40 men under me and it keeps me mighty busy seeing that they are on the job and that the finished material gets to the erecting side in time not to delay the locomotives. My shoe bill is a heavy one, because I have to cover a lot of ground every day and there is little time or opportunity for going into the fine points of dealing with the workers. The grievance committee is going to keep busy anyway and it is a waste of time for me to worry much about the boys, whose leaders are working overtime to look after their interests. I have all I can do to keep things moving.

Another thing—it would appear that some sort of a superman is required to fill the foreman's position. You want a man to be a master craftsman, to carry all the responsibilities of getting output and dealing with other departments, and on top of this to be an expert on management—a regular operating vice-president. And what do we get out of it? A lot of responsibility and worry and a little more money than an ordinary mechanic. We have no union looking after our welfare and interests and we are even "docked" for being sick or taking a vacation.

You will probably not dare to publish this, but why side-step the real issue? If you are going to try to start something, why not come clean and lay all the cards on the table, face up? Please consider as confidential my real name and location.

"Bill Black."

"Top Sergeant" cold-blooded

Michigan.

To the editor:

The commentary of the "Top Sergeant" in the August *Railway Mechanical Engineer* discloses that there still exists a railroad supervisor lacking in that primary attribute to the successful handling of men and problems—"latitude and thought."

We are no longer in the era of "constituted authority" which was the law of the masters, but in a community of interest where every man feels a sense of responsibility to both the company and his fellowmen. The masters of finance and industry have themselves become reconciled to this inevitable fact. Public opinion is its pathfinder; it is founded on the teaching of Christ—justice, sympathy and kindness. Discipline, however, need not be compromised. This we can administer without entailing sacrifice. These sentiments appeal to decency and the hearts of men and make for loyalty and happiness, and the germ when fertilized will permeate the atmosphere, infecting those in all departments and everyone will thereby profit.

The inference of "Top Sergeant" that the army countenances the practice he advocates is folly. As an officer of the Engineers, U. S. A., where discipline is a primary factor, I never witnessed such cold blooded treatment of men. If a "Top Kick" of mine had attempted to exert his will by coercion, I would have immediately "busted" him and put him in the ranks.

A measure of a man's ability to forge ahead is directly proportioned to his willingness and ability to study, accept and assimilate new laws and ideas. It isn't so much what he knows, as it is how he came to know what he knows. In the case of the "Top Kick" he accepts no new ideas from any source—management, salesmen, mankind, or otherwise. How supreme and secure he must feel in his limited domain. It is inconceivable to me that a man could be inspired to take such an attitude toward his fellowmen. It tinges with the deliberations of one soured on labor, management, self and mankind generally.

Captain Blood.

Backs up "Top Sergeant"

New Jersey.

To the editor:

I am very much interested in the discussion which "Bill Brown's" article has stirred up and wish to take this occasion to say my hat is off to the "Top Sergeant."

Here in my opinion as a railroad shop foreman who *knows* how to handle his men and get a real day's work out of every one of them. I will bet the cigars any time that "Top Sergeant" can take "Bill Brown's" gang and not only get greater outputs but also make such a favorable impression upon the men that if they were given their choice they would prefer to stay in "Top Sergeant's" gang.

No other industry or vocation has ever produced a finer body of men than our American railroads, but up to the present time of writing not one department has yet reached that mollycoddle stage where the men expect to be petted and coaxed into doing their day's work. The supervisor who has the courage to say: "By G—! I want it done this way and right away," never fails to get the cooperation which produces the desired output.

I fully agree with "Top Sergeant" that there is altogether too much of this brotherly love stuff being spilled. It may work out all right in fiction or the movies but in actual practice you will find it a pretty tough job to keep down the cost of production after you once start singing sentimental lullabys to your men. I also believe as the "Top Sergeant" that "Bill Brown" has missed his vocation and should be addressing audiences from the pulpit and not from a work bench on the shop floor.

Mr. Editor, if you really wish to learn something about how much sentiment there is in the human nature that a shop foreman has to contend with, just make arrangements with some railroad to temporarily masquerade yourself in this capacity and address your prospective gang in the manner "Bill Brown" advocates. I warn

you right now to be mentally prepared for the biggest razzing you ever got in your life.

It does not require much of an imagination to picture the delightful atmosphere of congeniality that must prevail in "Bill Brown's" department—what a wonderful improvement over the Garden of Eden it must be—where new workmen are cordially invited to take off their hats, get acquainted and are informed to be very careful about straining themselves for a few days; where a royal welcome awaits every so-called sales engineer who has a mythical story of wonderful tool performances to relate—where operators are expected to stop their machines while retrieving some valuable nut or bolt and where the foreman has time to make a scientific study of the men's point of view and then makes allowances for the cussedness found in human nature.

It may be that the railroads are now looking for the kind of shop foreman "Bill Brown" recommends but I personally will doubt it until the day arrives when I am paid to visit other shops for observant purposes—until I have once been allowed to select a machine tool which I know my department badly needs and until there is no longer need for a foreman to scour the scrap yard for a couple of apprentice boys who prefer to consume their "Lucky Strikes" on the company's time.

F. O. Reman.

"Objects to 'Top Sergeant's" arguments

Lorain, Ohio.

To the editor:

"Bill Brown" certainly did start something as evidenced by "Top Sergeant's" comments in the August *Railway Mechanical Engineer,* page 493. It is good to get the viewpoint of men, and without quarreling with their ideas we may at least try to prove or contest the soundness or practicability of their methods in dealing with employees or other affairs in their shops.

"Top Sergeant," I have read carefully your comments. You may be a top sergeant for all I know or care, but from a mere shopman's point of view, "granted that your opinions express your methods," you belong to a class of supervisors which is rapidly disappearing. Adopting the attitude of, "I am Monarch of all I survey; there is none my power to dispute," may be to you the essence of glory, but to the man in the shop it is ridiculous.

Your first contention, Why should a shopman play in the town band? Well, why don't you deny him the right to be a church member or an attendant at Sunday school? There would be just as much sense to it.

Second, calling his men together for a talk. That one item, proven by experience, has done more for production and general welfare than all the "drivers" in the world got out of their men.

Third, reading the railway journals. Why, my dear old top, your very words show how necessary it is that you get those bundles of journals out of their covers. Read, learn and digest!

Fourth, new employees. Did you ever stop to consider that no matter how good and experienced the new man may be, it takes a little time for him to accustom himself to his new surroundings, and the best mechanic that ever lived would need more than twenty minutes to prove his ability to a "hard-boiled" guy?

Fifth, new tools. Sure, you are not reading the journals and their advertisements, so you can't very well know, but lots of us know that the shop tools now being sold are far in advance of some sold two years ago.

Sixth, sales engineers. Have not had any experience with them, so cannot express any opinion.

Seventh, conservation of material. For this we agree as one of the best ideas put forward by the railroads, but, "Serge," if "Bill" dropped the only one inch nut he had, would you insist that he get an order for another instead of picking that one up?

Eighth, relationship to foremen of other departments. No, it is not Sunday school stuff, but good business sense. You can have competition between the different departments without bucking one another.

Ninth, attitude towards apprentices. At the recent centennial celebration of Akron, Ohio, among the exhibits were working models of both steam and electrical driven locomotives, complete to the minutest detail, the building of which, we were told, was done entirely by the apprentices of different railroads. Such work could not have been done by apprentices that were treated "rough" as you advocate. The August *Railway Mechanical Engineer,* page 511, contains a report of work done by apprentices of the Kansas City Southern, also showing their photographs. Do they look like a lot of dumb-driven cattle, as evidently you would have them?

"Top Sergeant," your comments are not in line with present-day tendencies, which are far superior to those of days gone by. Again, let me ask you to read your journals; come out from behind the clouds and into the light of day.

Joseph Smith,
Boilermaker, Baltimore & Ohio.

Slave-drivers not wanted

Bristol, Va.

To the editor:

"Top Sergeant's" viewpoint and treatment of the men under him are the principal causes of most of this dissatisfaction and unrest among workingmen today.

No man in authority who is clothed in his right mind wants a large labor turnover. Yet how can a man such as "Top Sergeant" expect any man to want to work for him? Everyone, with the exception of a few "Top Sergeants," has agreed that the contented workman is the best workman. A man cannot be contented working for a sour, fault-finding, get-to-hell foreman.

A foreman of the "Top Sergeant" variety is out of place in the railroad shop of today. The few that are left should be relegated to the corn and cotton fields, and to the construction camps, there to end their days viewing the business end of a mule in their daily toil, where they can vent their spleen to their heart's content. Their mouthings will be lost on the mule and will harm no one but themselves.

Although I am not in the mechanical department, I am glad that I work for a railroad where the management believes in treating the employees as human beings.

Buck Private.

H. J. Forster, secretary of the American Railway Association, announces that the modifications of car service Rule 11, set forth in his circular No. 2524 have been adopted by the association, as shown by the letter ballot which he recently recorded. This rule provides for marking freight cars with both nominal capacity and load limit, and for showing the cubical capacity with the inside dimensions.

Bulletin No. 9 has been issued by the Railway & Locomotive Historical Society, 6 Orkney Road, Brookline, Mass. The principal article is a 12-page sketch of the history of the Portland Company, Portland, Maine, as a former prominent builder of locomotives. This company, still flourishing in other lines, has built no locomotives since 1907. In 1852 it built the first locomotives for the Panama Railroad, and in 1882-83 built 100 for the Northern Pacific. Another bit of history contained in this pamphlet says that the New York & Erie, in 1856, employed 500 men, owned 203 locomotives and had a telegraph with 60 telegraph agents "so that any occurrence on the road could be instantly made known to the officers."

S. P. and U. P. acquire three-cylinder 4-10-2 locomotives

Tractive force of S. P. with booster is 95,700 *lb. and that of U. P. with no booster is* 78,000 *lb.*

RECENTLY the American Locomotive Company, New York, delivered to the Southern Pacific 16 three-cylinder locomotives of the 4-10-2 type and one of the same type to the Union Pacific. These locomotives have a new wheel arrangement which is a development from the 2-10-2 type in which the two-wheel leading truck has been replaced by a four-wheel truck.

The Southern Pacific locomotives, which will be known on that road as the Southern Pacific type, are used for hauling passenger and freight trains over the Sierra Nevada mountains where the maximum grade is 2.2 per cent. The Union Pacific locomotive, which will be known as the Union Pacific Overland type, has been operated for some time on the western end of the road and its performance is also to be carefully observed on all the other lines of the system: namely, the Los Angeles & Salt Lake, Oregon Short Line and the Oregon-Washington Railroad & Navigation Company.

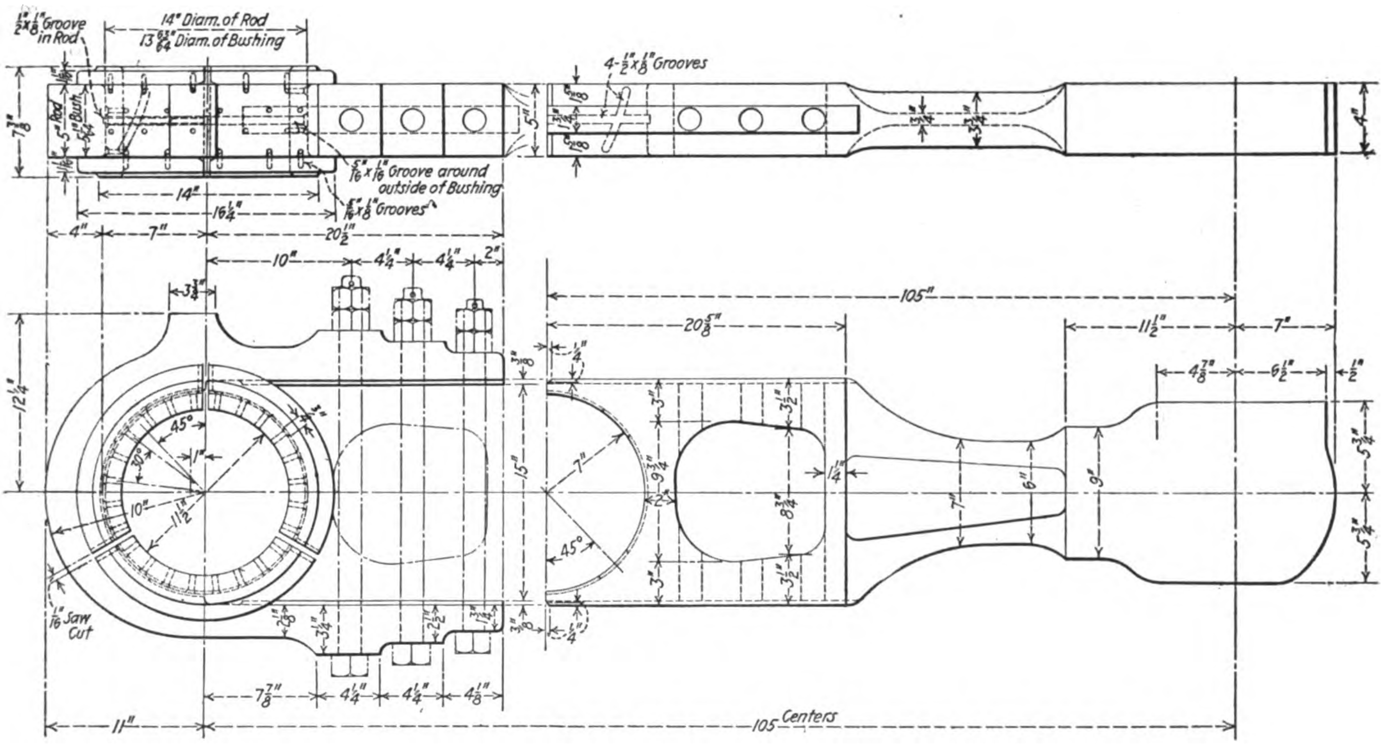
The Southern Pacific locomotives weigh 442,000 lb., of which 316,000 lb. is on the drivers, 65,500 lb. on the front truck and 60,500 lb. on the rear truck. They carry 225 lb. boiler pressure; the cylinders are 25 in. in diameter, the strokes being 32 in. outside and 28 in. inside, and the driving wheels are 63½ in. in diameter. With a maximum cut-off of 70 per cent, they develop a tractive force of 83,500 lb., which is increased to 95,700 lb. by the trailer booster. These are the most powerful non-articulated locomotives yet built. They burn oil and are equipped with Worthington feedwater heaters.

The Union Pacific locomotive weighs 405,000 lb., of which 288,500 lb. is on the drivers, 60,000 lb. on the front truck and 56,500 lb. on the rear truck. It carries 210 lb. boiler pressure and, like the Southern Pacific locomotives, the cylinders are 25 in. in diameter. The stroke of the outside cylinders, however, is 30 in., while that of the inside cylinder is the same as on the Southern Pacific locomotives. The driving wheels are 63 in. in diameter. With a maximum cut-off of 85 per cent a tractive force of 78,000 lb. is developed. Semi-bituminous coal is used as a fuel and is fired with an Elvin stoker.

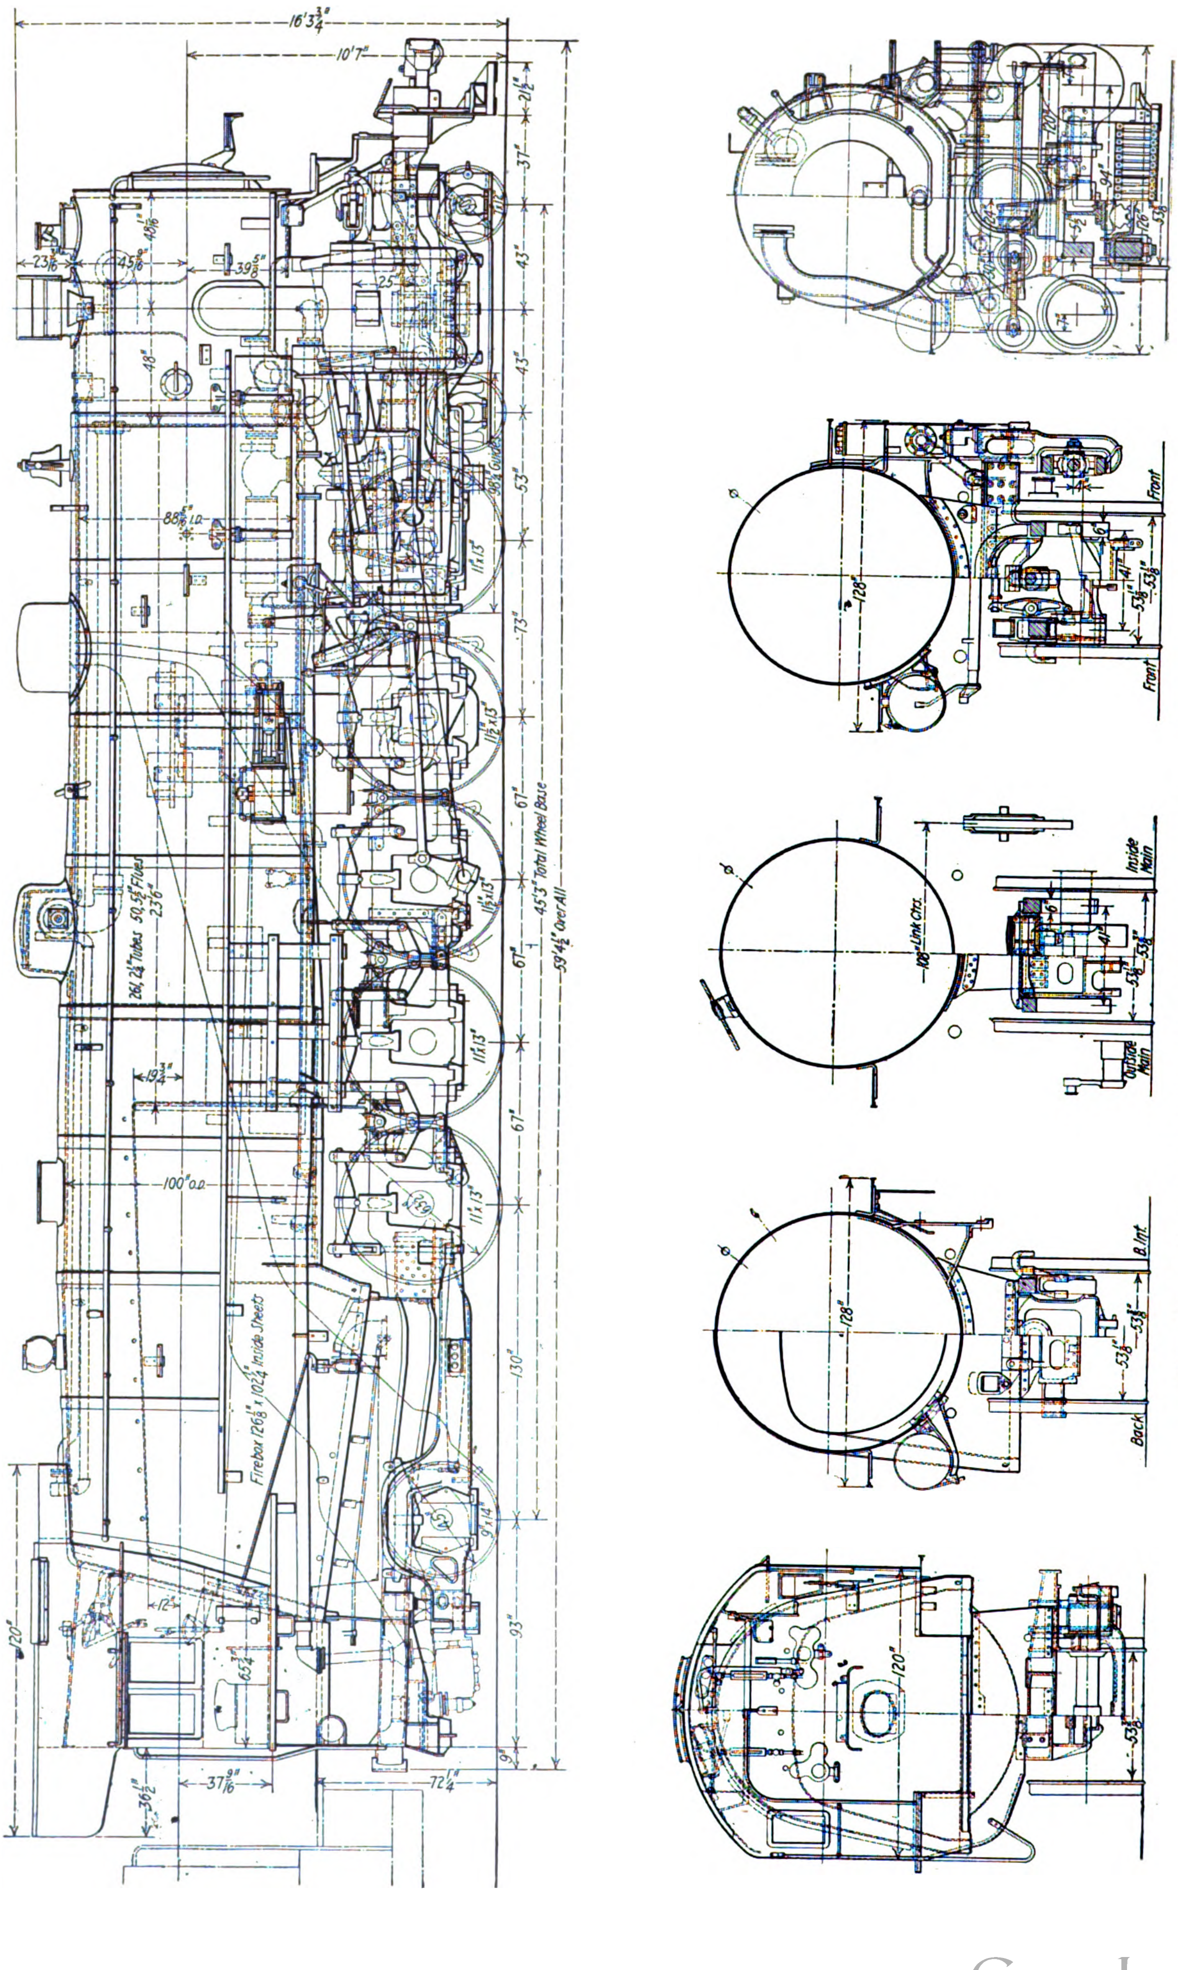
Boiler equipment

The boilers of these locomotives do not differ materially from the usual type of design. The overall length of the Union Pacific boiler is 49 ft. 7-7/16 in., while that of the Southern Pacific is 49 ft. 1¾ in. The other general dimensions of the Union Pacific boiler are slightly smaller than those of the Southern Pacific. The boilers of the locomotives of both companies are equipped with 50-unit Type superheaters.

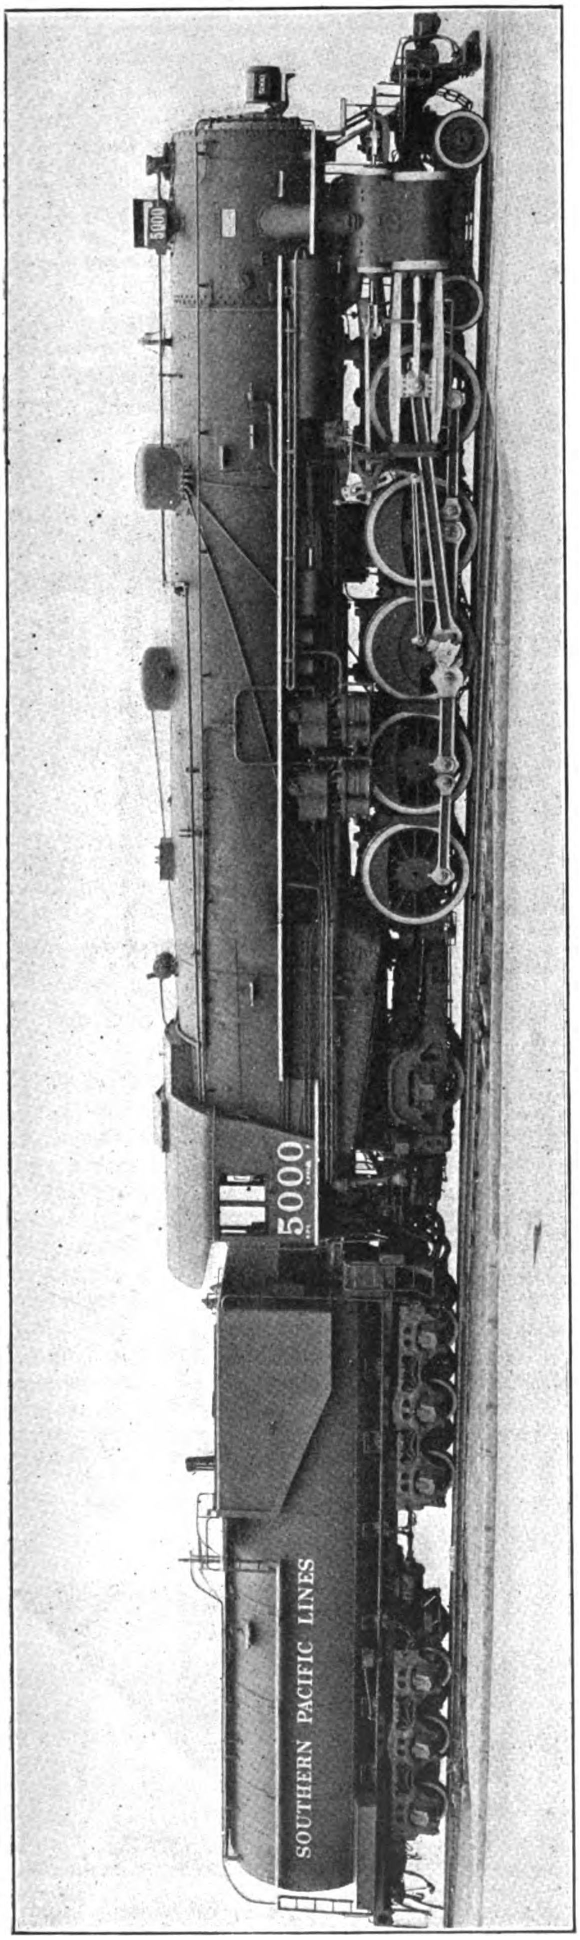
In the Southern Pacific locomotives the Bradford front end throttle is used which is located in the superheater smokebox between the superheater and the main steam cylinders. This provides superheated steam for operating auxiliaries, such as the air compressors, feedwater heater, headlight generator, oil atomizer and the blower. Two Westinghouse cross-compound air compressors are mounted on the right side of the locomotive beneath the



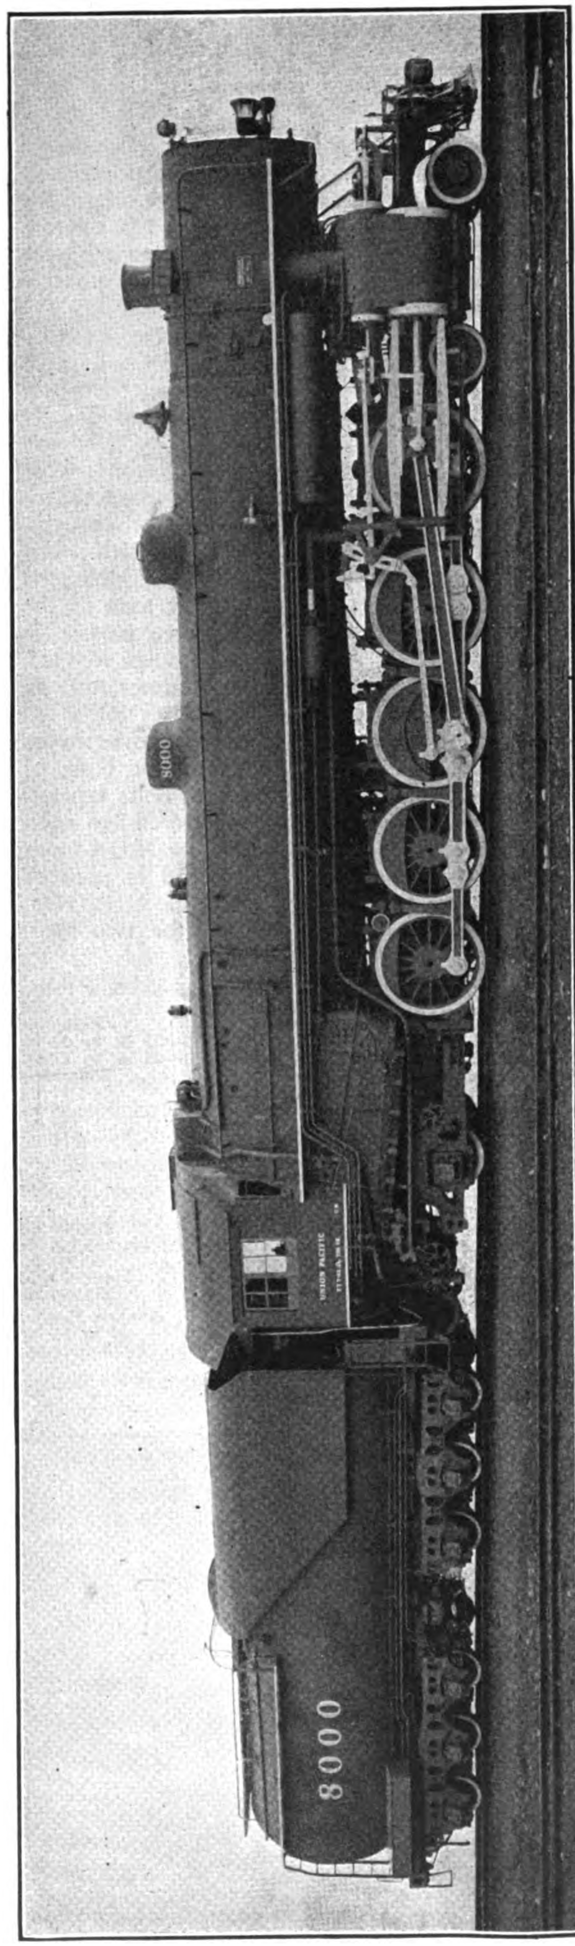
Middle main driving rod designed with an adjustable front end with rotor bushings and a strap back end with floating bushings



Elevation and cross sections of the 4-10-2 Type Southern Pacific locomotive



Southern Pacific, three cylinder, 4-10-2 Type locomotive which develops a tractive force of 83,500 lb. at 70 per cent cut off and 95,700 lb. with the booster, making it a powerful non-articulated locomotive



Union Pacific, three cylinder 4-10-2 type locomotive which develops a tractive force of 78,000 lb. at 85 per cent cut-off and 210 lb. boiler pressure—Total weight of locomotive, 405,000 lb. and with tender 647,500 lb.

running board, while on the Union Pacific the same size New York air compressors are mounted on the left side of the locomotive.

Running gear

Steam distribution is controlled by the usual outside valve gear. The valve stems of the two outside steam chests are extended and are connected just ahead of the chests by the same arrangement of levers used to operate the valve for the third cylinder on the three-cylinder locomotives previously built by the American Locomotive Company. The valve chambers of these locomotives are bushed to take 11-in. piston valves. They are operated by the Walschaert gear, controlled by the Alco Type E power reverse gear on the Southern Pacific engines and by the Franklin precision gear on the Union Pacific locomotive.

The middle main rod of a three-cylinder locomotive is rather difficult to get at for repairs. In order to reduce the wear of the bushings to a minimum, these rods are provided with an adjustable front end with rotor bushings and a strap back end with floating bushings. The back bushing, which fits over the crank axle of the second pair of drivers, is divided into three parts. It contains four rows of 5/16-in. holes, 12 holes in each row, alternately spaced. The holes are countersunk ¾ in. on the outside. This arrangement provides for equal distribution of the lubricant as the bushing moves in its fit around the pin. The strap dovetails on the body of the rod and is held in place by three 1¾-in. bolts tapered 1/16 in. in 12 in. Two nuts are put on the end of each bolt which are prevented from coming off by No. 4 taper pins, 2½ in. long. The weight of the rod is reduced by an opening through back end of the rod.

The principal dimensions and data for the two locomotives are shown in the following table:

Railroad	Union Pacific	Southern Pacific
Type of locomotive	4-10-2	4-10-2
Service	Passenger	Passenger
Cylinders, diameter and stroke	2—25 in. by 30 in. 1—25 in. by 28 in.	2—25 in. by 32 in. 1—25 in. by 28 in.
Valve gear, type	Walschaert	Walschaert
Valves, piston type, size	11 in.	11 in.
Maximum travel	6¼ in.	6 in.
Outside lap	1⅛ in.	1½ in.
Exhaust clearance	None	1/16 in.
Lead in full gear	3/16 in.	3/16 in.
Cut-off in full gear, per cent	85	70
Weights in working order:		
On drivers	288,500 lb.	316,000 lb.
On front truck	60,000 lb.	65,500 lb.
On trailing truck	56,500 lb.	60,500 lb.
Total engine	405,000 lb.	442,000 lb.
Tender	242,500 lb.	244,000 lb.
Wheel bases:	Union Pacific	Southern Pacific
Driving	22 ft. 6 in.	22 ft. 10 in.

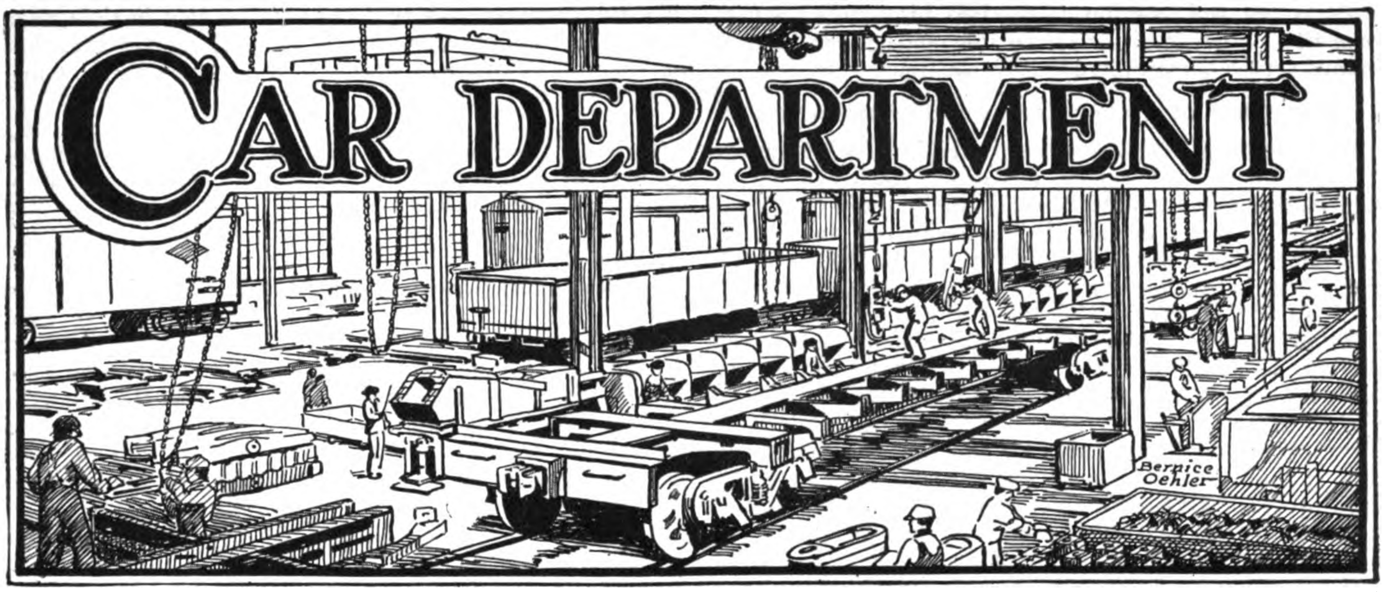
Now is the time to check up on terminal conditions and see what should be done to get ready for winter



Freight car maintenance problems*

Need of improvements in design in order to reduce repair costs—Modern shops and equipment should be provided

By C. G. Juneau
Master car builder, Chicago, Minneapolis & St. Paul, Milwaukee, Wis.

UNDOUBTEDLY, the greatest problem today in connection with freight car maintenance revolves on the constant endeavor of the railroads to obtain the maximum use of the car unit. The utilization of cars is the product of their loading and their movement. Successful attempts are continually being made to load each car with greater tonnage and to increase the distance each car is hauled per day. Again, wherever there is an opportunity to fit the trains to the traffic, this is being done so that the tonnage will be handled in fewer trains, and thus effect a saving in those transportation expenses that fluctuate with train mileage. The trend of this endeavor on the part of the railroads to obtain greater use of their cars and trains is pictured in Fig. 1.

Result of increased weight and capacity

Along with this steady increase in the utilization of the freight car, has gone a steady change in the construction and strength of the car. The all wooden car is fast disappearing and its place is being filled by the composite car and the steel car. During the past twenty years the average carrying capacity of a freight car has increased from 29.4 tons in 1903 to 43.1 tons in 1922. The light weight of cars has also increased. The all-wooden box cars acquired in the 1890's weighed from 14½ tons to 16 tons whereas the composite box cars acquired in 1919 weighed 23½ tons. Fig. 2 shows the replacement of the all-wooden freight car by the composite and the steel car. Fig. 3 shows the increase in the average carrying capacity of freight cars of the country and pictures the trend of increased light weight of cars as shown in the case of box cars.

These changes in the weight and capacity of the freight car have resulted in its increased punishment. Although freight cars have been greatly strengthened to meet the additional burdens placed upon them, and while there is really no disagreement throughout the country covering the strength requirements of these cars, the railroads do, however, continue to have bad order cars in great numbers. What is actually occurring is increased punishment to freight equipment because of the lack of cushion formerly provided in train movement by reason of the wooden car disappearing. If operating methods are to proceed as in the past, there is absolutely no question but what resilience will have to be furnished through the medium of a suitably designed draft rigging, or else we may expect distinct failure of parts following a progressive cycle, depending upon considerations of relative strength factors.

Furthermore, while the freight car as a whole has been designed and constructed to meet modern operating conditions, many of its parts are not equal to the tasks imposed. The draft gear seems to be about the weakest part of most cars, when, as aforementioned, it must be depended on to lessen the punishment received by the car. Very little has been done to improve the foundation brake rigging, and air brake apparatus on the modern car is compared to the old unit, and yet experience shows the air brakes are responsible for approximately one-fourth of the transportation delay to cars made in bad order in train yards and running repair tracks. Rail-

* Contributed by the Railroad Division at the Spring Meeting, Milwaukee, Wis., May 18 to 21, 1925, of the American Society of Mechanical Engineers.

roads cannot well continue accepting this kind of a performance if they desire to keep the modern car in continuous service a maximum amount of time.

Importance of proper design and construction

The design and construction of freight cars was never of more importance than it is today. Each acquisition of new equipment should be made the subject of special study by the mechanical and transportation officers to determine; first, the actual necessity for the cars; second, the size and capacity which will give the greatest net returns to the company, and third, the type of car. A thorough study of the design should be made before any cars are built. It is undoubtedly true that maintenance expenses are considerably increased due to failure to take everything into consideration when preparing the designs. The only way to insure that new cars when acquired will be a credit to the mechanical department, is to keep designs of each type constantly under way. Each detail must be critically analyzed, compared with existing types and an endeavor made to eliminate its defects. A comparison of the final result with the original will usually show a surprising number of changes, and will convince any one of the necessity of giving long and painstaking attention to every new design.

Few cars designed today can be criticized as lacking in strength in the essential parts, but it is also important that cars should be light, so they can consistently be made easy to repair, and well protected against corrosion. Few cars meet all these requirements, and their failure to do so has led to severe criticism of car design from a maintenance and operating standpoint.

In the matter of designing and constructing a modern car, the details of material, as previously mentioned, cannot be judged entirely from strength requirements. The question of deterioration over a period of years needs to be given serious thought. If a roof becomes defective in one-half the time that the rest of the principal portions of the car require attention, and has to be repaired, the car is held out of service. This emphasizes the need of studying the parts in relation to their cycles of renewals, so that they may be grouped and consequently reduce the days detained on the repair tracks.

Sources of deterioration of freight cars

One of the greatest sources of deterioration of freight cars, irrespective of the material or construction, is corrosion or decay, which continuously exerts its destructive influence whether the equipment is in service or not. In the case of wood parts there are very few renewals which are not directly caused or at least greatly hastened by decay. A close analysis of failures which appear to be purely mechanical will generally disclose the gradual destruction of the piece by decay as the original source of weakness. The matter, therefore, of preventing the destruction of material, by chemical action in the case of metal and by the propagation and growth of the destroying fungi in the case of wood, is worthy of considerable study.

A car must also be considered from the standpoint of items effected by friction or transportation such as wheels, brake shoes, draft rigging, couplers and the trucks as a whole. The wear and failure of these parts constantly increases with the greater utilization obtained from the modern car. To withstand this greater hardship it is essential that proper designs and proper material be employed in each case. The use of correct metals and alloys requires a more thorough study. Certainly we never should use a brittle steel for parts subject to great shocks, or soft iron for parts subject to much friction, yet this has been done, resulting in failures. Sills, framing members, etc., are subject to strains that in time wear them out. These parts must be of such construction that shocks and vibrations incident to the service will not impair their efficiency.

Consideration should be given to building a car strong enough to meet general requirements and yet so put together, materials and otherwise, as not to be unduly heavy. In other words, cars should be designed to have a high ratio of load to total weight. This is important because dead weight is a factor in train movement. A five year average of the freight trains handled on one western road showed that for each net ton of revenue freight carried, the train hauled 1.2 tons of dead weight, exclusive of locomotive and tender. Approximately, 66 per cent of the cars hauled were loaded. It is a well-known fact that automobile manufacturers have made successful attempts to reduce the weight of automobiles, yet retaining or increasing their loading capacity. Certainly this matter needs very serious study on the part of car designers.

It is not a good policy to sacrifice materially the design of a car to accommodate details. Standards, however, are unquestionably excellent. At the present time details that will absolutely interchange between all different cars are too few. As long as cars are built for some particular service we may expect to have a difference in construction due to the commodity to be transported. The present tendency is toward refinement in car design and if it

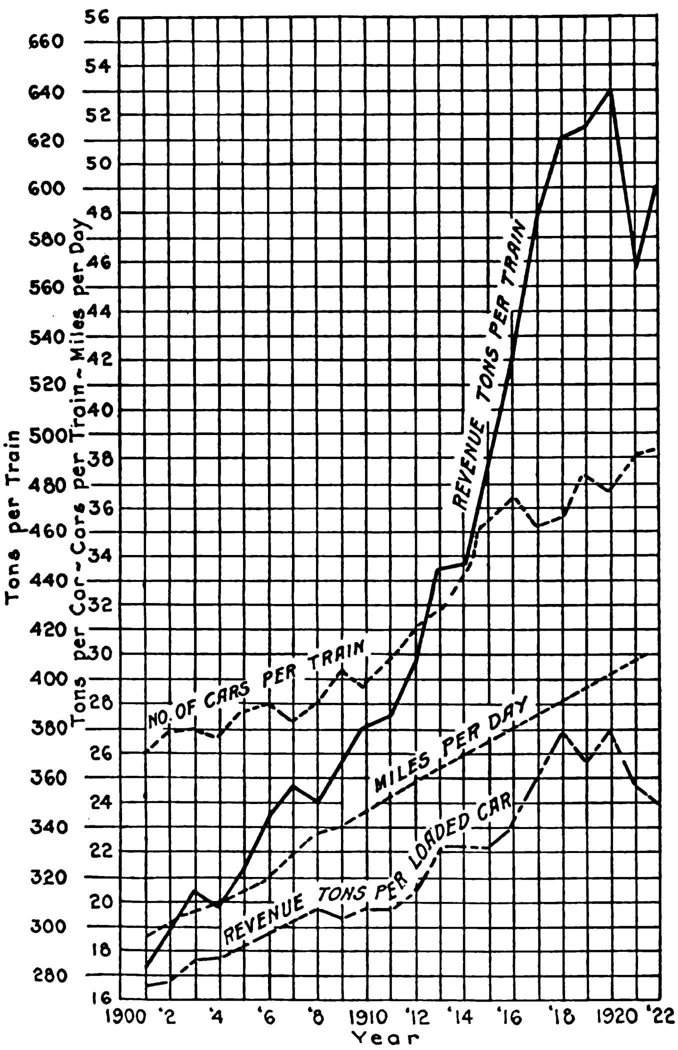


Fig. 1—Chart showing the increase in freight car utilization since 1900

continues, equipment built a few years hence will probably be radically different from what is considered standard practice today. Already a remarkable number and variety of new designs of cars have been introduced.

In the matter of maintaining freight cars it must be continually kept in mind that cars that can be kept in continuous service with a minimum cost of maintenance

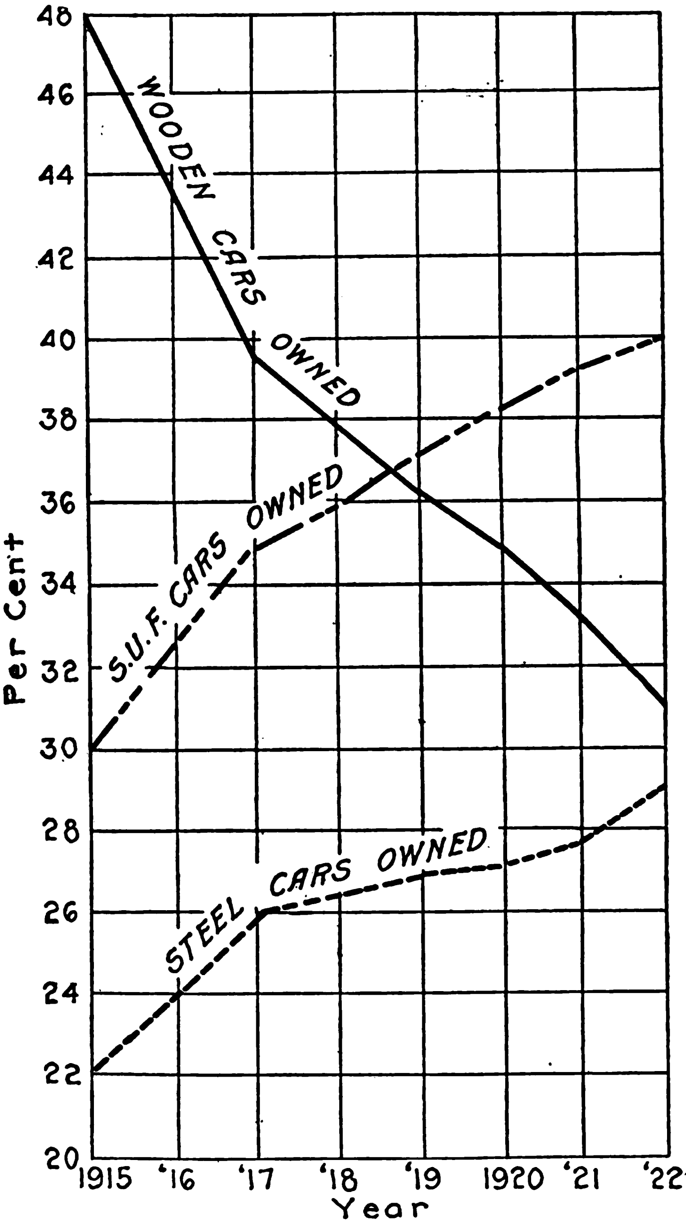

Fig. 2—Chart showing the replacement of wooden freight cars by those of composite and all-steel construction since 1915

and which are sufficiently efficient to protect the lading in transit, mean dollars and cents to the railways. One road found that during a five years' period the cars on its line averaged between 25 to 56 days per year in bad order; also that the frequency of repairs averaged between 22 to 34 times per year. In other words a defect occurred for about every 500 miles the car moved.

Freight cars subject to many defects

Freight cars are subject to many defects which make them unfit to operate. Some are of little consequence; others require considerable time and labor to repair. In general, freight car repairs are governed by frequent renewal of certain parts and infrequent renewal of other parts. Freight car repairs are roughly divided into two classes: light and heavy. Light repairs consist of work done to offset current wear, breakages and loss of parts accruing from ordinary handling and movements of cars day by day. Heavy repairs accrue, generally speaking, from three different sources: wrecks, ordinary wear and tear as accumulated over a period of years, natural deterioration, and obsolescence.

To a certain extent, the problem of handling light repairs is readily dealt with; that is, given a reasonably adequate supply of tools, material and standard parts, and a certain force of men, that part of the maintenance problem will take care of itself and cars will be switched on and off of the rip track daily without much fluctuation. It has generally been found that six light repair cars are repaired during the day to every one left over at the end of the day, and it is this feature of the work which results mostly in an increase or decrease in the bad order car situation.

The situation with respect to heavy car repairs is entirely different. Repairs to cars due to wrecks and accumulated ordinary wear and tear are usually accomplished by replacements in kind, but more extensive work is required to overcome obsolescence as in this case it becomes necessary to strengthen and remodel the cars to overcome inherent weakness in design and construction. These cars remain a comparatively long time out of service and require a comparatively large expenditure to place them in proper condition. It is in the handling of heavy car repairs therefore, that the greatest opportunities exist to produce economies and reduce the time that the cars are held out of service.

Studies made of maintenance policies and work done in repairs over long periods, particularly in relation to the life of equipment, indicate that under conditions prevailing for the last thirty years, freight cars have been given heavy repairs by owners on an average of once every eight years. In other words, at the end of the eighth year the car, if normally maintained in the meantime so far as wearing parts are concerned, would require heavy repairs, which would again make is good for another cycle of about eight years, after which it would be again given heavy repairs for another eight years of service if found to be of proper design, or would run with a limit of repairs until worn out. In this case, the life would be extended to approximately twenty-four years or more, with a few years added to the life of the car where it was permitted to run in some minor service until entirely worn out. If, at the end of the second cycle, the car was found not worth repairing, it would be run about four years longer until worn out. In actual practice there is considerable variation of these figures so that studies have developed that the average life of equipment has been approximately twenty years, particularly the body, there being a factor of safety required in the trucks which made them serviceable for about five years longer than the body. Practically all freight cars in the country have been depreciated on the basis of a twenty year life for the body and twenty-five years for the trucks, as set up by the Interstate Commerce Commission for valuation purposes.

Frequency of heavy repairs

There is no specific record of the average frequency of rebuilding or heavy repair work by classes of cars. The general data indicates an average period between heavy repairs to box cars of about nine years for those equipped with modern steel underframes and about eight years for those with wooden underframes and relative construction. Modern refrigerator cars will require about seven years between heavy repairs because of the necessity of going over the insulating feature as well as overcoming structural deterioration. Stock cars will run about nine years

due to their light construction. Coal cars will run from nine to ten years whether all steel or composite. Steel floor sheets usually last about eight years and the side sheets about nine years, so that if false floors are used for a while, the cars can be run about nine years. This has been experienced with the character of metal used in the past, which has been unable to withstand sulphuric acid coming from the coal.

The wisdom of having freight cars in good condition cannot be doubted, and the expense of maintenance is justified, particularly where the general condition of equipment is such as to require heavy work to overcome what we might call inherent obsolescence. In other words, where the proper cycle of heavy repairs as previously explained, has not been maintained in due course, there develops a degree of deferred maintenance, and to a certain extent, obsolescence, which must be overcome sooner or later.

In order to maintain a normal situation as to design, construction and obsolescence, the average age of equipment should be carefully noted at all times, as this reflects whether or not old equipment is being retired as due, and replaced with new or rebuilt equipment. It has been customary to assume an average life of twenty years for freight cars. Assuming that a road has an ownership of 100,000 cars normally at all times, then from year to year it should retire or rebuild an average of 1/20 of 100,000 or 5,000 cars, and should acquire new equipment each year equal to the number actually retired and not replaced with rebuilt equipment.

It will be noted that a road has the choice of two policies in maintaining its equipment to overcome inherent weaknesses. It can retain its equipment for a longer period by overhauling and improving existing cars, or it can retire and replace the cars with new equipment at a more rapid rate. The policy to be followed depends upon many considerations, such as finance, operating expenses, and the extent of obsolescence.

Appropriations for freight car maintenance

The matter of appropriations for freight car maintenance deserves special study. Operating revenues have many mouths to feed and when heavy retrenchments in operating expenses become necessary it is to a certain extent inevitable that the maintenance departments bear more than their proportion of such retrenchments because maintenance work can be temporarily deferred without immediately destroying the effectiveness of the transportation machine. However, injudicious savings in maintenance results in actual loss to a road through increased transportation costs and, therefore, it should be determined where economy ends and loss starts in the retrenchment of maintenance expenses. An ideal condition would be to have the repair work equalized over the twelve months' period by arbitrary charges against income in the months of great business for credit and used during periods of revenue depression.

It is costly to make repairs to cars without proper repair facilities and equipment, and conditions become worse as the weight and capacity of cars increase. It is, of course, out of the question to provide numerous costly machines and tools where only a few cars are handled, but some repair tracks that turn out as many as 100 cars a day, have hardly no equipment for expediting the work.

The labor cost of repairs made on large repair tracks is usually much too high. Careful planning of major operations, and the judicious expenditure for facilities will do much to correct this condition. This problem again is a financial one and a road has the choice of three policies to pursue; first, resort to man-power due to inadequate facilities; second, add a few machines or tools each month so as to gradually reduce the repair expenses, and, third, spend a considerable sum immediately to equip the shops and repair tracks with the needed facilities. Obviously the policy to be pursued will depend upon the road's finances though no road can long afford to pursue the first policy for the lack of repair facilities decreases net earnings. Capital account expenditures cannot be made to better advantage at this time in any direction by the railroads than through provisions for modern repair shops and equipment. In the past the amount of money expended by the railroads for logical repair shop facilities has been lamentably out of proportion with the amount of money expended for cars and locomotives, resulting

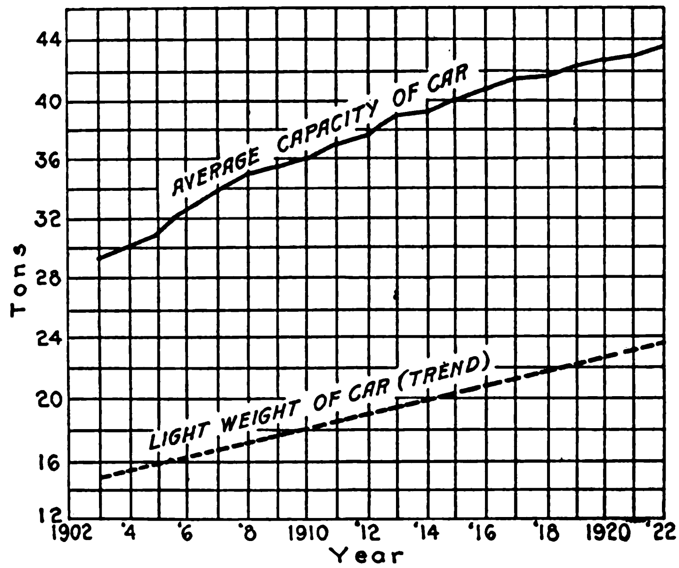

Fig. 3—Chart showing the increase in capacity and light weight of freight cars since 1902

in inadequate facilities for needed repair and modernizing work. The conclusion is that every advance in the art of car design should be met with a corresponding advance in the facilities for maintenance.

There is every reason to believe that the traffic on railroads in this country will increase as rapidly in the future as it has in the past, and that the locomotives and cars will continue to grow larger. Bigger power is demanded at all times and yet to haul a maximum train not only requires strengthening of freight cars, but roadways, bridges, engine houses, shop facilities and tools. It must be remembered, that when the freight cars are not used to the fullest degree they present a corresponding loss in all these elements, such as makes these extreme and uneven developments oftentimes show a poor net result.

Every freight car involves not only the cost of maintenance, but interest on the investment and current depreciating charges, both factors being higher because of increased investment cost. The object of the design of cars and the installation of facilities to make the maintenance cost relatively low, should be to increase the days of service by decreasing the days of detention in bad order because the greater present day cost of maintenance, interest and depreciation charges imposes upon proper railway management the requirement of greater availability for constant use.

In 1924 the Northern Pacific carried 3,607,987 revenue passengers. The average distance carried was 114 miles, and the average fare collected was $3.65. The company paid out in taxes that year $8,500,000. Therefore it required the entire gross amount received from the first 2,328,767 revenue passengers to pay the 1924 tax bill.

Air Brake Association Convention

THE following are abstracts or summaries of several papers, reports and discussions given at the thirty-second annual convention of the Air Brake Association. A brief account of the early proceedings of the opening session appeared on page 371 of the June *Railway Mechanical Engineer* and abstracts of a number of papers and reports were published on page 471 of the July issue, in which space was not available for the inclusion of those given here.

What are you specifying and getting in foundation rigging?

This report called attention to the common practice of assuming that if the piston travel (with the brakes applied) is of the proper amount and the brake shoes are of sufficient thickness to indicate lasting until the car reaches the next inspection point, or its destination, the car is in suitable condition to proceed as far as the brake conditions are concerned. Modern cars have, however, reached the stage where brake rigging is to a considerable extent hidden from view so that the time required for inspection for clearances and freedom from movable parts striking or binding, is well nigh prohibitive in trains en route, and is practicable only on the repair tracks or at lay-over points. It is therefore essential that all assurance possible be provided against such troubles by the design of the equipment and specifications to cover this design when the cars are built or reconstructed.

The report contained recommendations for the testing of air brakes on cars having both one and two brake cylinders and concluded with the following comment: "Improvement in car design seems to receive due attention in the way of applying all new features and developments that tend toward greater strength and wider ranges of utility until there is little room left on the cars for the proper installation of brakes. In view of the fact that brakes are first among the factors for safety and economy, it is suggested that when making up the design for cars it is highly consistent to provide ample room for the proper installation and operation of efficient brake equipment. This is equally important when getting up specifications for new cars or remodeling old equipment. The saving in cost of maintenance a few years later will have yielded large returns."

This report was contributed by the Northwest Air Brake Club through its committee, including Mark Purcell, Northern Pacific; James Elder, C. M. & St. P., and C. C. Ferguson, Great Northern.

Discussion

In discussing this report one member suggested that brake beam release springs are not always necessary and that half shoes be used in testing instead of removing the shoes entirely on one pair of wheels as recommended in the report. Mr. Purcell, in reply, pointed out that the removal of the shoes gives the maximum angularity of equalizers and indicates the probability of their striking parts of the car or truck and thus throwing all the braking duty on one pair of wheels, or two pairs in the case of a six-wheel truck.

To minimize the rapid wear of foundation brake gear and the development of slack it was suggested that the Committee on Recommended Practice establish a limit of at least 1/32 in. of case hardening on all brake rod and lever pins and bushings.

Report on recommended practice

The changes in practice recommended by this committee were accepted with a few exceptions. Paragraph A under air compressors was changed to read, *"Intermediate* valves should also be placed in the steam supply branch to each compressor so either can be stopped for any purpose." Throughout the entire report where the word "re-bored" was used in connection with cylinders, the words *"re-bored, or ground"* were substituted to comply with modern methods.

Under main reservoirs the association voted that a ½-in. drain cock *and Street ell* be located at the lowest point of each reservoir. Paragraph C under triple valves requiring that the ring opening positions be marked on the piston and the ring re-applied in the same position was referred back to the committee. Owing to the objections of some roads to the use of gasoline for cleaning triple valve parts and possibly creating a fire hazard, it was recommended that gasoline *or suitable cleaning compound* be used to clean all internal parts of the valves. Strong objection was made by some of the members to the use of any oil whatever in triple valves and consequently in Section K under triple valves the word *"graphite"* was substituted for "anti-friction oil."

Triple valve slide valve leakage indicator

In testing triple valves the leakage test provides that the exhaust port of the triple valve be coated with soapsuds to ascertain the amount of leakage when the slide valve is in emergency position and again when the slide valve is in release position. No limit is fixed as to the amount of leakage, so that the amount permissible is largely dependent upon the judgment of the individual test rack operator. Even if all individuals judged the amount of leakage uniformly there is a variation with the soapsuds that is independent of the operator. It has been found in testing a triple valve with one solution of soapsuds that the bubble will burst in five seconds, while another solution will hold a bubble for 18 seconds on the same valve. In addition, the temperature of the solution has a bearing upon how long the bubbles can be held.

A device lately developed, known as the triple valve slide valve leakage indicator corrects this situation and insures that all operators will judge slide valve leakage on the same basis which will permit positive condemning of triple valves when the leakage has passed a permissible value.

The principle of the slide valve leakage indicator is to cause the leakage from the slide valve passing into the triple valve exhaust to enter a chamber above a reservoir containing water. Pressure is therefore built up in this chamber which forces the water from the reservoir into a column adjacent thereto. It will be evident that the more the slide valve leaks the more rapidly will pressure be developed in the chamber above the water and the more quickly the water will rise in the water column. The rate at which the water rises in the water column is measured and this is taken as a basis for determining whether triple valves are in the proper condition.

The indicator is simple in construction but without a test code cannot be used. The following therefore covers

the test code to be used with this device. With the triple valve in the emergency position, time should be taken from the second to the third graduation and must not be less than the following: New—seven seconds; cleaned —five seconds.

In release position, the time should be taken from the second to the fourth graduations and must not be less than the following: New—ten seconds; cleaned—four seconds.

In the graduating valve tests, the time should be taken from the second to the third graduation and must not be less than the following: New—eleven seconds; cleaned —five seconds.

This report was submitted by the Manhattan Air Brake Club which is now conducting tests with the slide valve indicator, the results of which will probably be available for presentation before the convention next year.

Discussion

Several members spoke highly of this device and said that as a result of somewhat extensive use they considered it one of the most valuable adjuncts of the triple valve test rack that has been developed in recent years. The indicator is apparently not more liberal than the soap bubble test but assures a greater uniformity in the valves. In any event, reliance must be placed on the honesty of the operator since with the indicator he can permit air to leak past the rubber application end and thus give a false indication. The general feeling was, however, that the indicator will give highly accurate and uniform results.

Report on passenger train handling

In the main, this report was intended to clarify several points brought out in the report last year. After devoting some attention to the possibilities of graduated release and six different methods of making brake pipe reductions, the effect of pressure on triple valve movements was considered.

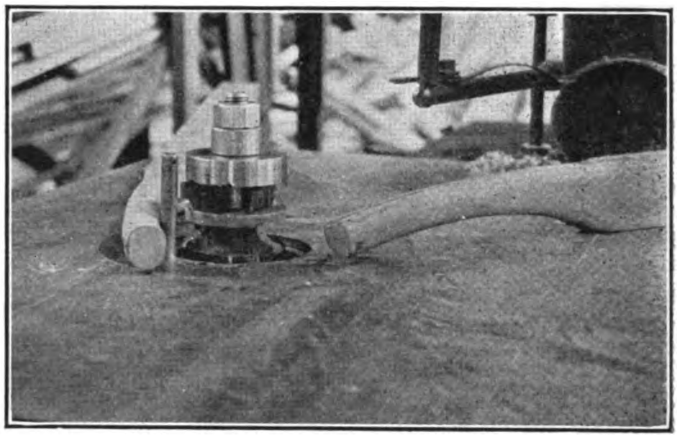
The report closed with a consideration of the relative advantages of the clasp brake as compared to the single shoe. These advantages were summarized as follows:

1.—Normal cylinder pressure per pound of brake pipe reduction.
2.—Shorter stops in emergency due to reduced brake shoe duty.
3.—Reduced brake shoe wear.
4.—Reduced brake shoe and truck maintenance.
5.—Less brake shoe dragging and reduced train resistances.
6.—Longer trains handled with less loss of time, using the same motive power equipment.
7.—Smoother stops.
8.—Fewer slid flat wheels due to shocks, stuck brakes and the transfer of load from one pair of wheels to another.
9.—Fewer hot journal bearings.

The report on passenger train handling was contributed this year by the Central Air Brake Club through its committee, consisting of James Elder, C. M. & St. P.; W. J. Devine, C. & N. W.; and L. M. Carlson, Westinghouse Air Brake Company

Device for forming handles on a wood shaper

THE usual method of forming the hand grips on wooden handles, such as used on hand trucks, is to mark out the general contour of the handles by means of a templet and then carve out the grips to shape by hand. This method requires considerable time and the finished handle is not as smooth as one turned out by the device shown in the illustration. It consists of two sets of forming tools separated by a collar. The two sets of tools, which are made from ordinary tool steel, are ground so as to form the finished contour of the handle.



Two sets of cutters quickly form the contour of the handle

The device is fastened on the spindle of a wood shaper. The handles are laid off to a templet and then quickly finished by the rapidly revolving cutters.

Decisions of the Arbitration Committee

(The Arbitration Committee of the A.R.A. Mechanical Division is called upon to render decisions on a large number of questions and controversies which are submitted from time to time. As these matters are of interest not only to railroad officers but also to car inspectors and others, the Railway Mechanical Engineer will print abstracts of decisions as rendered.)

Wheels changed on account of owner's defect and the application of journal bearings within the thirty day period

On May 28, 1923, the Carolina, Clinchfield & Ohio applied to C. I. & L. car No. 18119, one pair of second-hand wheels and journals R. & L. No. 1, on account of a chipped rim on one wheel, the other being second hand. The old journal bearings were reapplied, as the billing repair card did not show the application of new bearings. On May 30, 1923, at a different point on the C. C. & O. system 136 miles from the point where the wheels were changed, one new solid 9-in. brass was applied to the same car at the R. No. 1 journal to replace a worn out brass. A charge of $2.06 was made against the C. I. & L. The car owner declined the charge for this journal bearing, contending that no charge should have been made for a subsequent application of a journal bearing when applied within 30 days of the initial application at the same journal location, on the same road and the same trip, as outlined in Rule 99, irrespective of whether the wheels were exchanged for owner's or delivering line defects. The C. C. & O. maintained that Rule 99 did not substantiate the claim of the car owner in that the brass removed and replaced at the time the wheels were changed on account of the owner's defects, does not constitute the initial application of the brass, and stated further that the repairing line had the privilege to decide whether or not there was sufficient service in the material to warrant renewing or replacing of the brass.

In rendering its decision, the Arbitration Committee

stated that: "The wheels were changed on account of owner's defects, and as only one journal bearing was charged within the 30 day period, the charge in this case against the owner is proper."—*Case No.* 1330, *Chicago, Indianapolis & Louisville vs. Carolina, Clinchfield & Ohio.*

Another case under Rule 32

T.A.R.X. car No. 25 was delivered by the Okmulgee Northern Railway to the plant of the Allied Refining Company on September 30, with two draft sills bent; one end sill broken; one end sill cover plate bent; one buffer casting broken; one pin lifter casting missing; one wrong draft gear Cardwell G-11-X, in place of a Miner friction gear; one wrong carrier iron; two wrong draft lugs; 18 lug bolts, which should have been rivets, and one common pin lifter which should have been full length. A defect card was demanded by the car owner in accordance with A. R. A. Rule No. 4, interpretation No. 1. The handling line refused to issue a defect card, claiming that the damages were not handling line defects, and contending that the defects were not caused by collision or impact other than that which occurred in regular switching, but by an ordinary draw bar failure, as there was no evidence that the car had been damaged due to any of the causes described in A. R. A. Rule 32. The car owner contended that the defect card should have been issued at the time of delivery according to A. R. A. Rule No. 4 which provides that the basis for responsibility should be placed according to the judgment of the receiving line under A. R. A. Rule 88. The car owner further contended that there was conclusive evidence to show that the damage to the draft gear was the result of unfair usage to the car.

In the decision the Arbitration Committee stated that: "The contention of the Okmulgee Northern Railway is sustained. The defects do not indicate delivering line responsibility. If the wrong repairs were not made by the Okmulgee Northern Railway it is not responsible for them."—*Case No.* 1329, *Okmulgee Northern Railway Company vs. Allied Refining Company.*

Proper application of temporary transverse tie rods

The Philadelphia & Reading presented bills to the Buffalo, Rochester & Pittsburgh for the application of temporary transverse tie rods to a number of B. R. & P. cars, during the months of February and March, 1923, according to Rule 21. The P. & R. stated that the temporary repairs were made because when the cars were delivered to its lines by the New York Central, in accordance with A. R. A. Rule No. 2, they exceeded its clearance limits on account of bulged sides. The temporary transverse tie rods were applied to put the cars in condition for safe movement over its line. Where the side sheets were worn or rusted, to such an extent that threaded rods could not be used, a clamp or hook end was necessary over the top angle. The P. & R. maintained that this application was proper and Rule 9 did not require the manner of application to be shown on the repair card. The car owner contended that from the manner in which the repairs were made that they were only temporary and were not chargeable against the car owner in accordance with Item *B*, Rule 21.

In rendering its decision, the Arbitration Committee stated that, "The application of transverse tie rods, according to Rule 107, Item 262, contemplates the use of rods properly secured with nuts, including necessary washers or plates at both ends. The application of the hook rods does not justify a charge against the car owner, it being considered as no repairs."—*Case No.* 1332, *Philadelphia & Reading vs. Buffalo, Rochester & Pittsburgh.*

Gondola car rebuilt in forty-five man-hours

D. & H. holds third repair contest—Three teams compete for silver cup and cash prizes

On Thursday, May 21, 1925, the car department of the Delaware & Hudson Company held the third of a series of car building contests at Carbondale, Pa. The problem on this occasion was the rebuilding of a Delaware & Hudson standard tandem twin-hopper bottom gondola car of 85,000 lb. capacity. The work consisted of assembling the trucks and rebuilding the steel underframe and wooden superstructure. Three teams of 16 men each, eight of which were wood workers and eight steel workers, competed. These teams represented the major car repair shops on the Saratoga, Susquehanna and Pennsylvania divisions, where work of this character is a routine performance.

The cars built in this contest are equipped with steel underframes and have wood flooring and super-structure, including the side stakes. The hoppers, with the exception of the side slope sheet are also of wood construction. An idea of the size and type of the car may be obtained from the illustration showing the car rebuilt by the winning team after it had been completed and placed in service. The distance over the striking castings is 38 ft. 1 in. and the distance between truck centers is 27 ft. 5½ in. The inside dimensions of the car body is 36 ft. by 8 ft. 6½ in., the distance from the top of the floor to the top of the side being 51¼ in. The large amount of wood construction performed upon the car was an excellent test for the wood working gang, which in the case of the Susquehanna division, which won the contest, completed its work in 25 man-hours; the steel workers completing their task in a little less than 17 man-hours.

The rebuilding of the car required the driving of 847 button-head rivets and the applying of 1,015 bolts of various sizes. The painting of the car required two gallons of red lead for the underframe, 3½ gallons of black paint for the truck and frame, three gallons of metallic freight car paint and one pound of white lead. The car is equipped with Wine hopper door appliances and side and end ladders, Miner draft side castings and Harvey draft springs. The trucks are of the archbar

type having cast steel truck bolsters and Schaeffer bottom connecting rods, brake hangers and truck levers.

The contest was started at 8 a. m. and continued uninterrupted, with the exception of an allowance of ten minutes after the completion of the steel work in order to make the necessary preparations for the wood work, until the car was completely built.

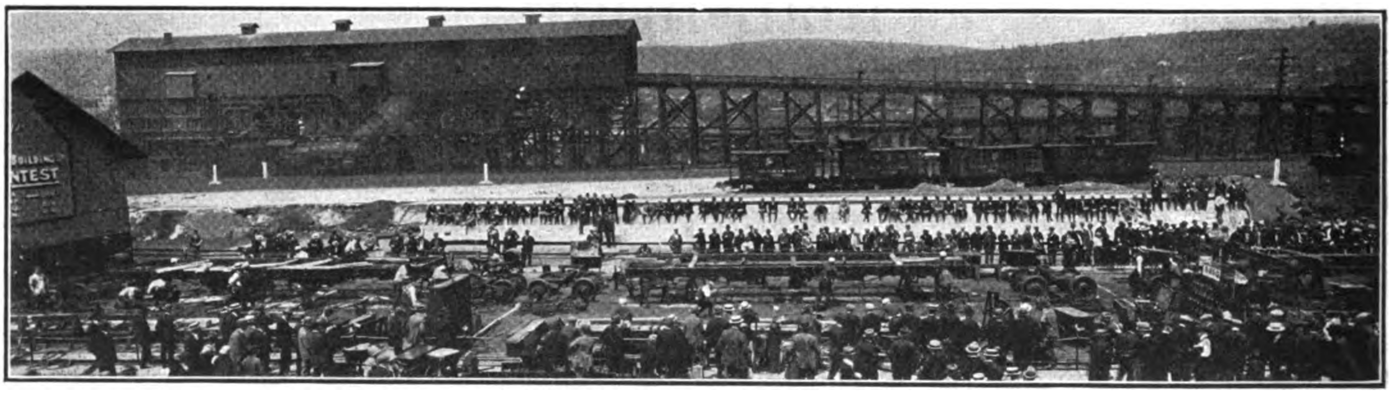
From the standpoint of the observer, the contest was of exceptional interest. No two of the three teams performed the work alike, or had the material arranged in the same manner. The team representing the Pennsylvania division assembled the underframe and then applied the draft gear and couplers. While this work was in progress, the work of rebuilding the trucks was completed. The next operation was to apply the steps, hand holds and uncoupling levers to the underframe, after which the car was turned over to the wood workers. This gang first applied the side sills, then the hoppers, floor and the ends and sides. After the various planks were placed in position for bolting, the trucks were run under the car and the work of applying and tightening the bolts on the woodwork, safety appliances, brake rigging, hand holds on the super-structure, etc., was completed.

Just before the start of the contest

The Susquehanna division assembled the underframe and applied the side sills, hoppers and floors in the order named. While this work was being completed, the trucks were assembled and made ready to place under the car. The next job performed was the application of the draft gear and couplers and the wood workers proceeded to apply the sides and ends, steps, hand holds and uncoupling levers. Upon completion of this work, the car was raised and the trucks run under, after which the work of applying the air brake apparatus and foundation brake rigging was completed.

The team which represented the Saratoga division applied the side sills as soon as the underframe was completed, finished the hoppers, applied the draft gear and couplers, and placed the trucks under the car, the trucks being assembled while the underframe was being built. The floors, steps and hand holds were applied at practically the same time as the air brake and foundation brake rigging. As soon as the uncoupling levers had been applied, each man on the team proceeded to tighten the nuts on the bolts and finish the various miscellaneous items.

The most noticeable variation in the steel work was that the teams from Colonie and Oneonta allowed the center sill channels to lie flange down on the horses until the center castings, splice plates and diaphragms had been secured. This appeared to be the best practice. The Carbondale workers, however, kept the channels on edge, making it necessary to steady them while the various operations were in progress. Another feature of the steel work which attracted considerable attention was a home-devised lever dolly bar used by a Colonie riveter which permitted him to hold a rivet and buck it up at the same time. Numerous other kinks and unique practices which were wholly permissible in the contest, were noticeable both on the steel work as well as that of the wooden super-structure.



Scene during the recent car building contest held by the Delaware & Hudson at Carbondale, Pa., May 21, 1925

The Colonie team was the first to conclude its steel work, finishing at 9:57 a. m. Oneonta was second at 10:05 a. m. and the Carbondale team was third, finishing at 10:50 a. m. In explanation of the wide divergence of time, particularly as between that of the Carbondale team

and the other two, an agreement was made between the three divisional car foremen prior to the contest which permitted them to assign the truck work either to the steel crew or to the woodworkers. Of course, in actual practice, truck repairers will do this work but these men

Presentation of the Birkett silver cup

were omitted from the teams as were the air brake men and painters. Carbondale chose to have its steel men assemble the trucks and this plan would have worked very well but for difficulties encountered in the work of assembling. It was thought that this arrangement would effect better equalization of the men on the team for when certain men were no longer needed on the steel work, they could be used on the trucks. The Oneonta and Colonie teams left the trucks to be assembled by the woodworkers.

Differences in practices among the woodworkers were also noticed by the manner in which they handled the side sills. It was generally agreed that the Colonie team used the best method: namely, that of allowing the sills to lie flat on the horses until the stake pockets had been secured by U bolts, after which the sills were turned over and the nuts run down with an air machine. Portable scaffolding appeared to be an advantage to the Oneonta team as compared with the ladders used by its competitors when bolting the side stakes, corner bands, securing the Wine ladders and other outside appliances.

The Susquehanna division team was the first to complete the task, which required 5 hr. 20 min., making a total of 42⅔ man-hours, exclusive of the air brake work, painting and stencilling. Adding this work to the total man-hours required to build the car, the entire job of rebuilding, painting and stencilling the car required a total of 45⅓ man-hours. The time required for this team to perform the various major operations was as follows:

	Man-hours
Trucks completed	1 hr.
Steel work	16 hr. 40 min.
Wood work	25 hr.
Air brakes	1 hr. 10 min.
Painting and stenciling	1 hr. 30 min.
Total	45 hr. 20 min.

At 4 p. m., approximately one hour after the Susquehanna division had completed its work, the first car was spotted and loaded at the coal breakers at Carbondale and left that point 55 min. later, destined to Wakefield, Mass., via the Boston & Maine.

The judges were P. Alquist, master car builder, Delaware, Lackawanna & Western; W. G. Knight, mechanical superintendent, Bangor & Aroostook, and C. P. Pfeiffer, master car builder, Buffalo, Rochester & Pittsburgh. This committee inspected each car upon the completion of each major operation and also made a

The winners—Susquehanna division team

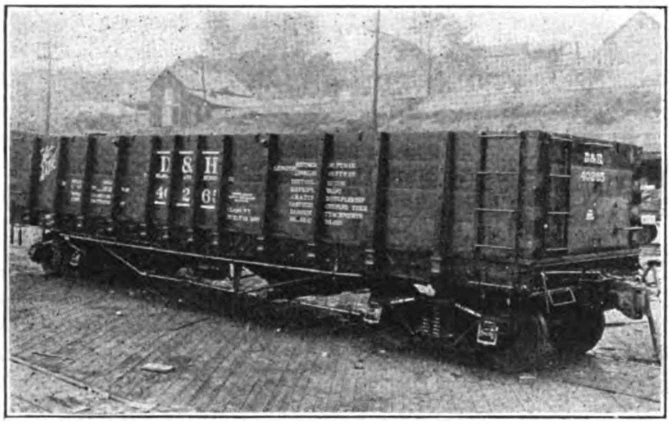
Seated (left to right): Alex. Ushtwant, Henry Neilson, Horace Landry, Fortunatus Kattansick, Percy Brush and Fred Lamb. Second row: John Knosvitch, Joseph Dilello, Lee Coburn, Warner C. Arndt, Albert Dilello and Fred Demesko. Standing: Claude E. Gregory, piecework inspector; Ross J. Comstock, foreman steel gang; Egnu Solowich, Daniel Patrick, Herman Wells, Louis Colone, Mike Truchan, Elmer Young and Rathbun J. Cook, foreman wood gang.

final inspection after the work was completed. It reported that in its opinion, the work of each team was of an equally high standard so that the status of each was fixed by the time required to complete the work. The prizes were awarded by Colonel J. T. Loree, vice-president and general manager, Delaware & Hudson, who was an interested spectator throughout the contest and complimented the winners on their excellent performance which won them the contest.

Approximately 500 persons witnessed the contest and the awarding of the Birkett silver cup to the Susquehanna division team for the second consecutive time. This cup is dedicated to the memory of the first foreman of the car department of the Delaware & Hudson. In addition to the cup award, each man on the winning team received a cash prize and a further cash prize was awarded to the Saratoga division team, which took second place.

Representatives of 23 railroads and 34 railway supply companies, as well as two inspectors from the Interstate Commerce Commission, were registered in attendance at the contest. A box lunch, prepared by the wives of the supervisors of the car department of the Pennsylvania division was served in the wood mill during the noon-hour to the guests of the Delaware & Hudson.

These contests, of which this was the third, are entered



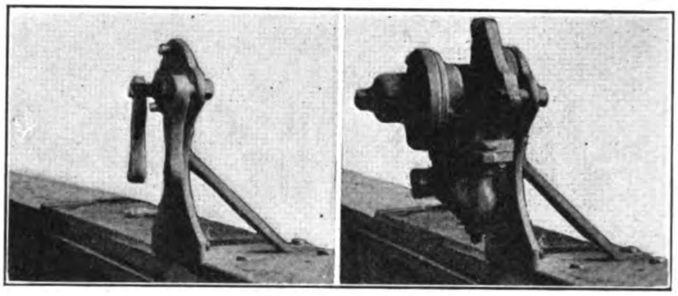
Car built by the winning team ready for service

into with a friendly spirit of rivalry and are not only interesting, but also instructive to the employees. One of the outstanding features is the material layout, which indicates in many respects efficient and economic car shop operation. The compensation of the employees in the car department is fixed on a piece-work basis and these contests afford an ideal opportunity to study that phase of car repair work. The ready accessibility of material stimulates production and the resultant increased output is reflected in the earnings of those on a piece-work basis.

The first of these contests, which was described in the January issue of the *Railway Mechanical Engineer*, was held at the Colonie shops on October 31, 1923. Five teams of six men each, selected from the major shops of the Delaware & Hudson participated, the winner of that contest being the Carbondale team which completed the task in 7 hr. 49 min. The second contest was held at the Oneonta shops of the Susquehanna division on May 8, 1924, at which time the super-structure of a 60,000-lb. capacity steel-frame box car was rebuilt and the trucks and draft gears assembled. Three teams of eight men each competed. The winner was the Susquehanna division team which performed the work in 6 hr. 30 min., or 52 man-hours.

A handy device for holding triple valves

A DEVICE for holding triple valves while they are being repaired is shown in the illustration. It is made of ¾-in. steel plate bent to 90 deg. and braced as shown. The working face of the holder is provided with two pins that fit snugly into the upper and lower bolt holes of the triple valve and two locking handles having inside



Left—Holder ready to receive triple valve; Right—Triple valve in position

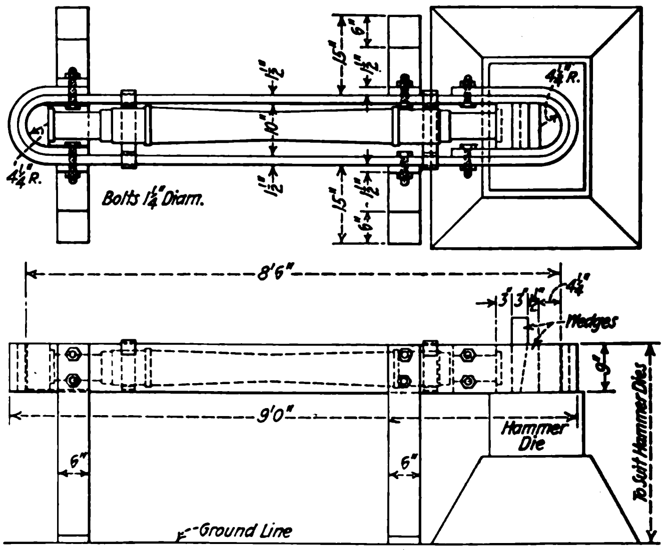
cam surfaces. The triple valve is placed on the holder by inserting the pins through the bolt holes and turning the locking handles upward. The cam surfaces serve as a wedge to hold the triple valve securely against the working face of the holder.

Tool for upsetting car axles

By F. L. Clark

Blacksmith foreman, Southern Pacific, Algiers, La.

THE reclamation of worn car axles is a perplexing problem which most all car departments have to contend with and many tools have been devised for upsetting car axles which have been more or less of a success. The tool shown in the illustration is simple in



Method of holding the axle during the drawing out and upsetting operations

construction, easy to handle and gives very good results.

The axle is first drawn out to length and then straightened in a centering machine to make it run true. Each end of the axle is then heated and upset so as to obtain

sufficient stock to make the collar after which the journal is turned on a lathe to make a new fit.

It can be seen from the following table that the axles are reclaimed until they are down past the lowest limit.

Size	Capacity in lb.	Amount center is drawn out	New size	Capacity in lb.
5½ in. by 10 in.	100,000	1¾ in.	5 in. by 9 in.	80,000
5 in. by 9 in.	80,000	1⅝ in.	4¼ in. by 8 in.	60,000
4¼ in. by 8 in.	60,000	1½ in.	3¾ in. by 7 in.	40,000

With this tool the center is drawn, each end upset and the journal turned for a new fit for $7.35 which includes labor and material, charging the axle at scrap price. Forty-five axles—90 ends— are upset in 7 hr., 20 min., which includes the trucking time to and from the shop.

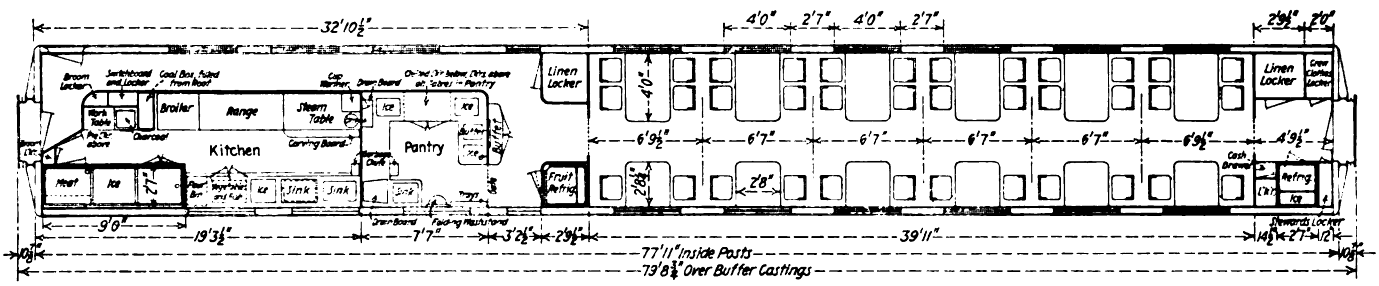
St. Paul to rebuild dining cars

THE Chicago, Milwaukee & St. Paul contemplates rebuilding its wooden dining cars with seating capacity for 30 guests, into 36 seat, steel underframe diners, and the first sample car was recently completed at the railroad company's shops, Milwaukee, Wis.

greater working room, as well as to provide locker space to make the car suitable for Coast line service. The practice on the C. M. & St. P. is to stock dining cars in Coast line trains at Chicago and Tacoma, Wash., the two terminals, and it is, therefore, necessary to take provisions for a 75-hour run. For this reason, an unusually large refrigerator is provided.

It will be noted that the refrigerator compartment near the end of the car has space for meat hooks, so that entire sides of beef can be placed in this compartment. The refrigerator is of the modern type, being iced from the roof. Other features in the kitchen and pantry are indicated on the floor plan.

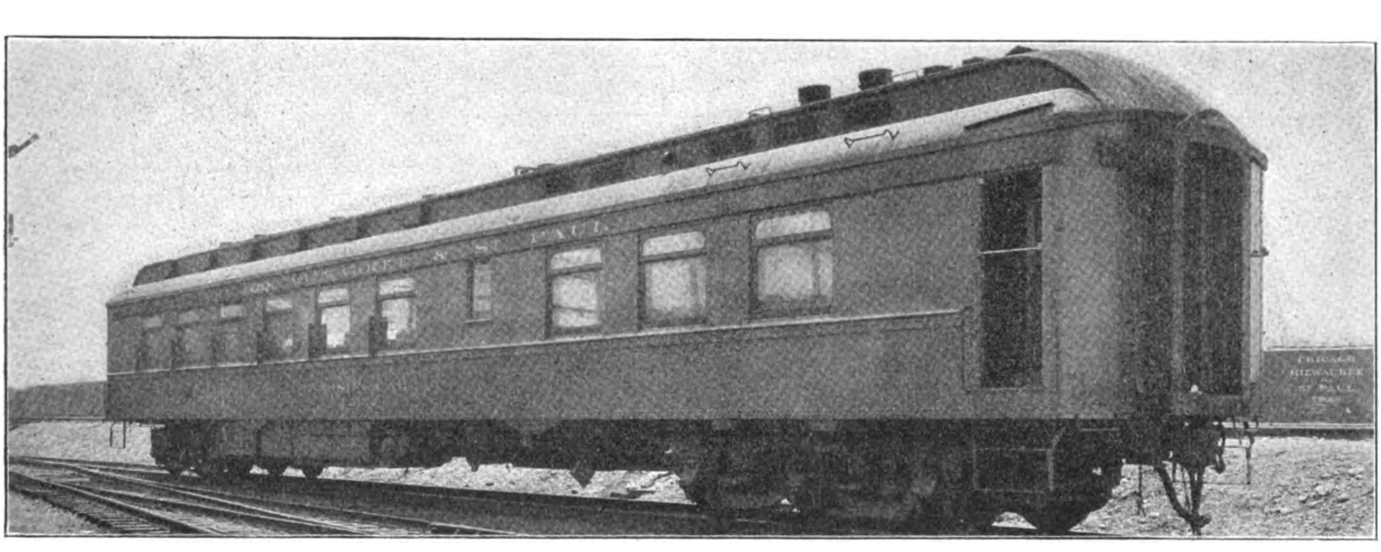
From the illustrations it will be noted that the usual standard depth of underframe is employed. In order to make provision for such an underframe, it was necessary to replace the wooden center sills with stringers and bring the steel underframe up close to the floor in order to obtain the usual clearance from top of rail to bottom of center sill. The object of making the sill of standard depth was to obtain an underframe together with the side sill construction of adequate strength to carry the



Floor plan of rebuilt C. M. & St. P. diner—Six additional seats in the dining room and unusually large kitchen space are provided

The rebuilt car is equipped with a steel platform and steel side girders of adequate strength to carry the weight of the car, equipment and passengers without the use of truss rods. The original car was of the ordinary vestibule type and in order to provide two additional tables

weight of the car body and equipment without maintaining the truss rods, originally under the wooden cars. A center sill of less depth than 26 in. in this case proved to be unsatisfactory from an engineering standpoint, when buffing stresses and direct leads were considered.



C. M. & St. P. diner recently rebuilt at Milwaukee shops—Steel underframe applied—Seating capacity increased

the end bulkheads of the car were moved out to the buffer beams, eliminating the side doors with the exception of one door at the kitchen end.

The arrangement in the kitchen and pantry is new, as additional space had to be provided in order to obtain

It will be noted that the center sills project 5¼ in. above the top surface of the cast steel double body bolster and platform casting. The reason for this offset is to avoid as far as possible alterations in the present wooden underframe, as with this construction it is only neces-

sary to remove the wooden center sills at the distance equal to the length of the steel underframe, leaving the platform intact. It will be noted that the platform casting is of the vestibule type, this arrangement permitting the

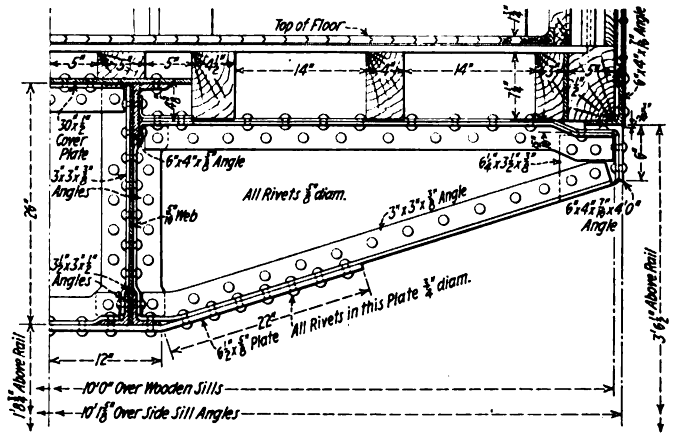
The interior view of the car creates an impression both of simplicity and of beauty

use of a standard underframe construction for both vestibule and blind end cars.

Interior finish and decoration

It will be noted that the contour and ceiling decoration is a departure from present practice, inasmuch as practically all moulding has been eliminated. The ceiling consists of a three-ply veneer covered on the underside with a ed. The ceiling lamps as well as the base of the ceiling fans have special ornamentations to match the side fixtures.

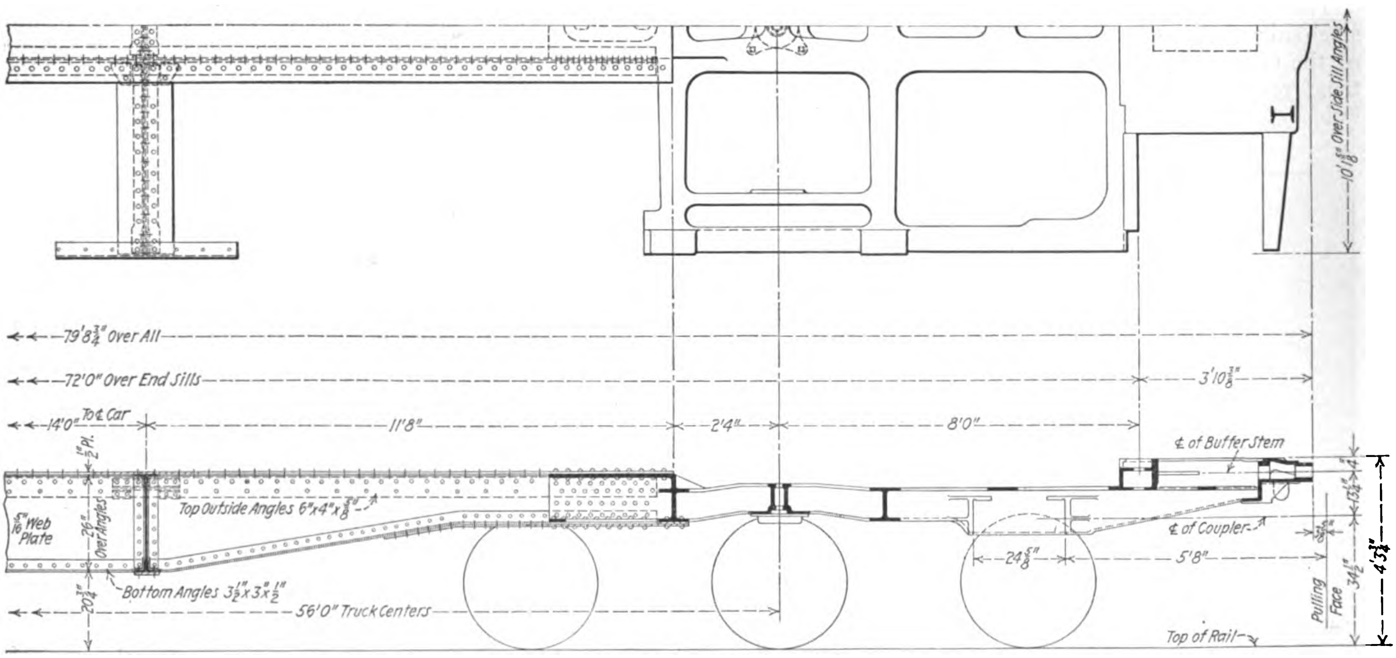
From the interior view it will be noted that the buffet is built to a height as used in dwellings. This was made



Cross-section showing arrangement necessary to accommodate the increased depth of center sill

to obtain a homelike appearance in the car. In place of the ordinary decksash, it will be noted that shutters in the form of grills are introduced in the upper deck.

Prizes of $25, $20, $15 and $10, and six prizes of $5 each are being offered by the general loss and damage prevention committee of the New York Central for the best articles containing practical suggestions for the reduction of loss and damage to perishable freight. The prizes are offered in connection with a campaign now being conducted by this road,

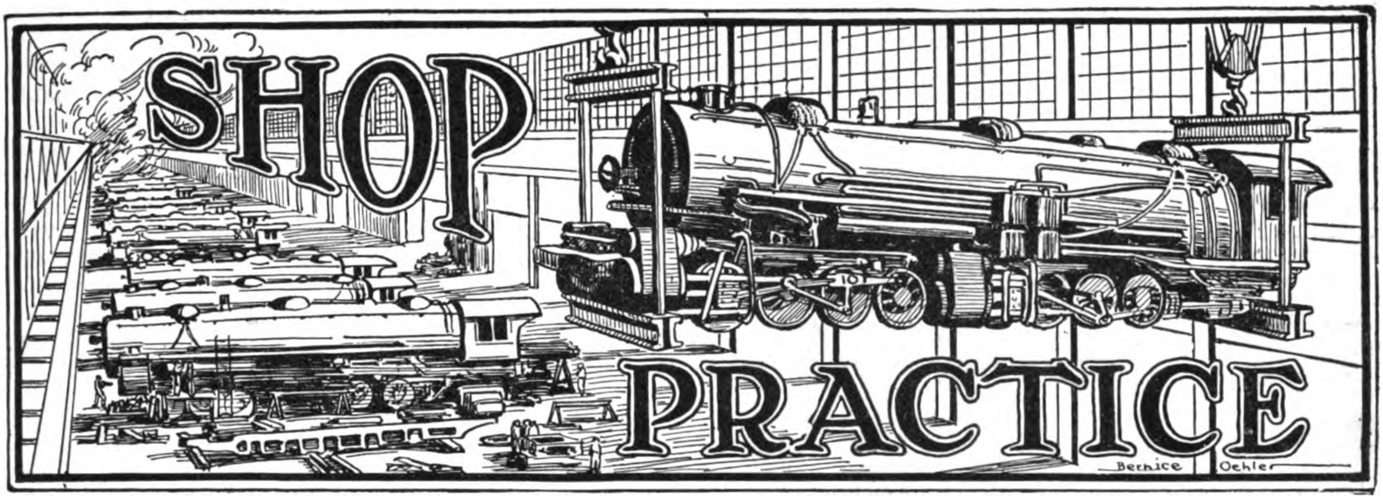


General arrangement of center sill and platform casting—Standard depth, 26 in. sill used

heavy burlap, the painting being light cream, stippled. The side finish is plain Cuban mahogany without any inlay or ornamentations.

The chairs are upholstered in black leather to match the carpet, which has a black background with a floral pattern in Chinese red. The side lights are especially designed for this car, with parchment shades, hand paint-

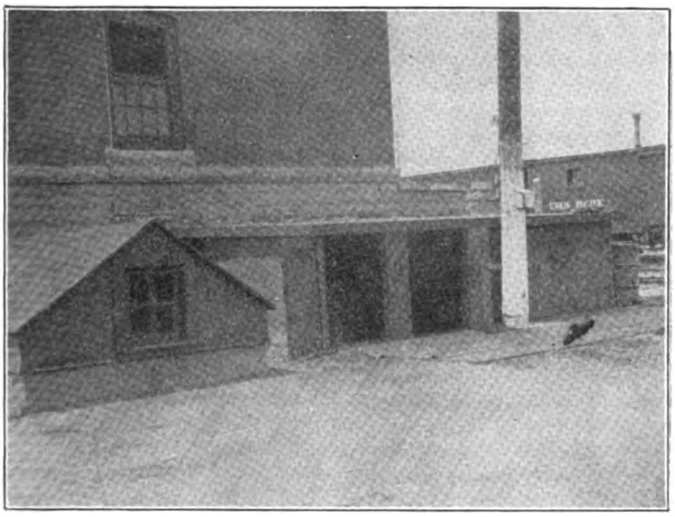
as a means of further reducing damage to perishable freight. The contest is open to all employees of the New York Central except agents at Class A, AB, B and C stations, general yardmasters and assistant general yardmasters, and supervisory officers of other departments occupying positions of similar rank. The papers submitted must contain not less than 500 words and not more than 1,000. The contest ends on August 31.



Handling locomotive supplies

Judicious location of the building containing supplies saves time, labor and material

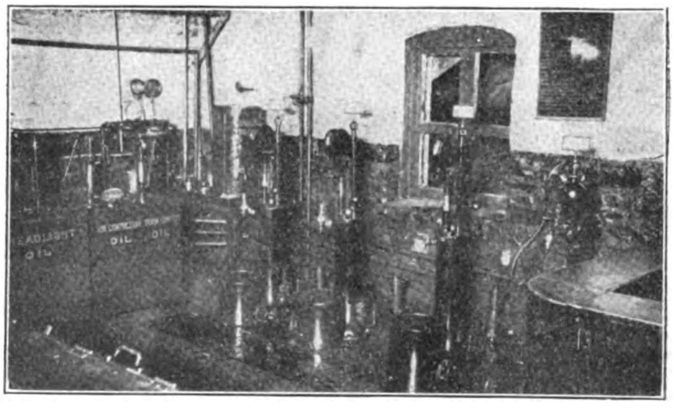
THE overall efficiency of an enginehouse in turning locomotives is dependent on the efficiency with which individual maintenance and servicing operations are performed, and one of these operations involving a magnitude of expense not always appreciated is handling engine supplies. The problem of efficiently supplying oil and other materials to engines was studied at the Union Pacific enginehouse, Cheyenne, Wyo., and a method developed which, having proved its merit, may be of suggestive value to other railroads.



Fifty-gallon oil barrels on two-wheel trucks are run into this shed from which they drain to the oil storage tanks in the supply house basement—The shed is air tight and heated in winter

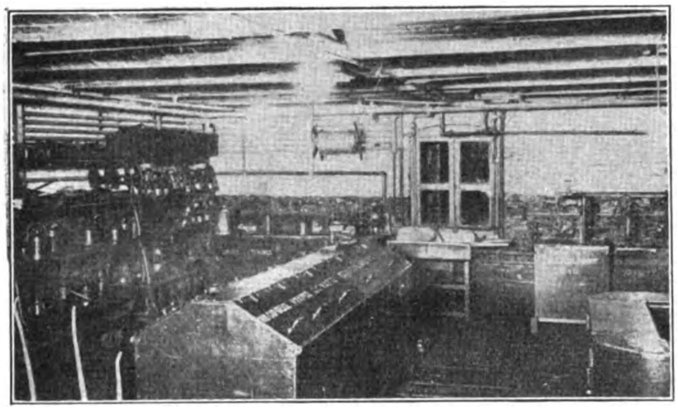
The method formerly in force at Cheyenne was to bring each day's supply of oil and materials needed for the engines from the general storehouse, located comparatively near the enginehouse but still too far away to be a convenient base of supplies. Time was lost going to and from the storehouse and it was impossible to maintain an accurate control of the materials issued. The brick building, shown in the illustrations and formerly used for waste reclamation and storage, was therefore converted into a supply house for engine oil and other materials. Being located adjacent to both the inbound and outbound tracks, it forms a convenient base for engine supplies which can be handled with much less labor than formerly. Material is saved and the entire operation of handling engine supplies is brought under the closer supervision of the enginehouse foreman with a resultant increase in effectiveness and economy.

During times of peak load 100 locomotives are handled at Cheyenne in 24 hours and by means of the new supply house conveniently located and fully equipped, it has been possible to reduce the number of men engaged in handling engine supplies to one man on each of three shifts, with a laborer on the day shift. When an engine comes to the enginehouse, the light supplies are taken off by the supply man, assisted by the hostler. When the engine is ready to be dispatched the supply man takes out valve oil, car oil, fusees, torpedoes and flags. Since the Union



Interior view of the engine supply room showing Wayne oil pumps—Lubricators are drained and the oil strained for re-use

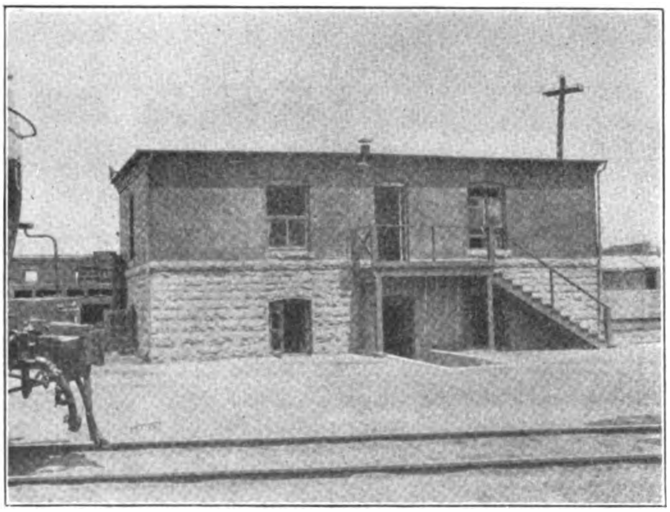
Pacific locomotives are practically all in pooled service, each locomotive carries its individual set of tools which are locked in an ingenious holding device on the front of the tender. These tools, therefore, are seldom lost, and need not be renewed except in case of breakage. The supply man also brings out to the locomotive lanterns, waste and a torch and checks the engine for the heavy supplies, including rerailers, switch chains, clinker hook, spout hook, shaker lever and knuckles. The supply man



Orderliness features the engine supply house, a place being provided for everything and everything being kept in its place—The sectional waste container is shown in the foreground

watches the dispatcher's board to see that outgoing engines are furnished with supplies in ample time to avoid delay.

The engine supplies are kept in the basement of the building, the other floor being occupied by two offices. Access to the supply room is readily had through the basement door shown in one of the illustrations. The arrangement of the interior is also clearly shown in the illustrations. Oil is furnished by means of four Wayne oil



Engine supply house reconstructed from waste reclamation and storage building at the Cheyenne enginehouse of the Union Pacific

pumps which draw from storage tanks beneath the basement floor. Oil is moved to the supply house in 50-gal. barrels on 2-wheel trucks which are run into a practically air tight shed built at one end of the supply house and piped to the storage tanks below the pumps. In winter the doors of this shed can be closed tight and, by means of steam coils on the inside, the temperature kept at a point where the oil will flow freely from the barrels to the storage tanks.

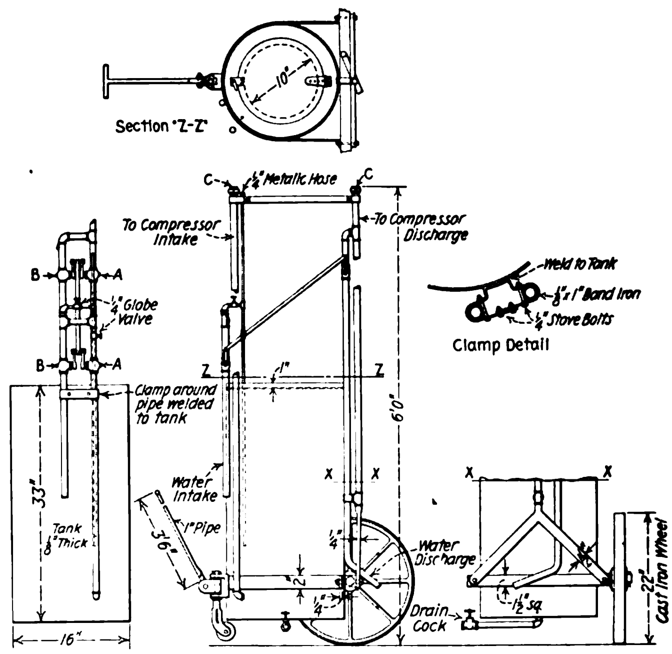
The engine supply house is kept very neat and orderly with a place provided for every item. Lanterns and torches are cleaned at the bench adjacent to the lantern storage rack. Lubricators are drained and the oil strained and re-used in order to eliminate as far as possible all waste of oil which represents just so many dollars and cents. Cellar grease is reclaimed by the regular supply men in their spare time. The grease as received at the supply house in barrels is picked over by hand to remove the dirt. It is then formed in cakes of specified standard sizes by means of dies in a pneumatic press. Thin cakes are built up to standard thickness by adding layers of the required thickness at the bottoms.

The experience of the Union Pacific with this carefully laid out and operated engine supply house indicates that the time and effort expended on it are well worth while. It makes possible considerable savings over the more common type in which the attempt is made to keep engine supplies in an old box car body, having neither room, light, nor facilities for handling any considerable amount of material.

Air compressor laundering equipment

ONE of the subjects discussed at a recent meeting of the Manhattan Air Brake Club was the method for laundering air compressors. Among the various devices proposed as giving excellent results was one used on the New York Central Lines East.

The laundering machine consists essentially of a tank



Drawing showing the construction of the air compressor laundering device

mounted on wheels and equipped with the necessary pipe and hose connections. Referring to the drawing, connections are provided to the compressor intake and discharge by means of six-foot lengths of ¾-in. metallic hose with suitable pipe fittings on either end. When circulating potash through the compressor, the cocks *A* are opened and the cocks *B* closed. When it is desired to circulate clear water through the compressor, the cocks

A are closed and the cocks *B* are opened. All pipe and fittings are ¾ in. with the exception of the steam line which is ¼ in.

The solution tank is 33 in high and 16 in. in diameter and is made of ⅛-in. steel plate. The top head is provided with an opening 10 in. in diameter which is sufficiently large for large pieces of potash to be dropped into the tank. This eliminates the necessity of having to break the potash into small pieces which is an unpleasant job, because the dust gets into the eyes of the workmen. This arrangment also eliminates the necessity of having to melt the potash into a solution before it is placed in the tank. The opening on the top of the tank is provided with a cover to prevent the solution from being splashed out on the workmen when engaged in starting the air compressor or moving the tank about the enginehouse.

The solution is kept hot by a steam connection to the compressor drain cock. Thus a connection to the shop steam line is not required. A tank of this capacity permits one charging of the solution to be used a number of times. Owing to the size of the top opening, the laundering machine may be used for cleaning parts other than the air compressor, such as feed valves, pump governors, etc.

A duel circulating system is provided for both solution and clear water. It will be noted from the drawing that the circulating pipe system is arranged in such a manner as to prevent water from getting into the solution and diluting it. A fresh water connection on the equipment affords a quicker way of circulating clear water through the air compressor than is possible when the laundering device has to be disconnected, the compressor shut off and a water connection then made at the compressor. In other words, when this device is connected to the air compressor and started, there is no need to make any further adjustments, except to turn cocks *A* and *B*, until the job of cleaning is completed.

The design of the laundering machine is such that the weight is reduced to a minimum and is balanced around the axle which permits easy handling by the workman. The wheels are 22 in. in diameter which allows the machine to be hauled readily over rails or small obstructions on the floor.

Master Blacksmiths meet at Cleveland

Many new methods are proposed and discussed—Development of welding has reduced blacksmith shop costs

THE International Railroad Master Blacksmiths' Association held its twenty-ninth annual convention at the Hotel Winton, Cleveland, Ohio, August 18-20, 1925. There were over 110 members in attendance. Two factors stood out prominently in the discussion of all of the reports, namely, the effect that the rapid development of welding has had on blacksmith shop work and the need of having proper and adequate machine tools and shop equipment. This latter factor was emphasized by trips to the plants of the Acme Machinery Company, the Ajax Manufacturing Company and the second machine tool exposition of the National Machinery Company, Tiffin, Ohio.

It was decided to hold the 1926 convention at Cleveland. The following officers were elected for the ensuing year: President, H. W. Loughridge, P. & L. E., McKees Rocks, Pa.; first vice-president, L. C. H. Weideman, C. C. C. & St. L., Beach Grove, Ind.; second vice-president, W. W. Shackford, A. C. L., Waycross, Ga.; secretary, W. J. Mayer, M. C., Detroit, Mich. Abstracts of a number of papers which were presented at this convention follow:

Jas. J. Egan (N. Y. N. H. & H.)
President

H. W. Loughridge (P. & L. E.)
First Vice-President

W. J. Mayer (M. C.)
Secretary and Treasurer

Autogenous welding

Two papers on autogenous welding were presented by E. M. Turner, A. C. L., Rocky Mount, N. C., and C. K. Abbott, L. S. W., Tyler, Texas. Autogenous welding has come into shop practice so rapidly and has

speeded up shop efficiency to such an extent that we find ourselves asking the questions: How did we get along before we had it, and what would we do now without it? Autogenous welding has probably saved the railroads more money and time in the repair and upkeep of worn and broken parts, especially that of locomotive frames, than any one process ever introduced into the railroad shop. In addition, many intricate forgings can now be made on short notice and with less expense.

It was generally conceded that both the acetylene and the electric methods each had its place and that one had advantages over the other on certain jobs. In some shops it is the practice to require all welders to make a test weld every three months and the men making the best test are the men put on the best class of work. In many shops practically all of the boiler welding is done with the electric method, as well as link motion work, while frames and cylinders are welded with oxy-acetylene with good success.

One speaker said that his road used both methods at the reclamation plant. Each job of welding and cutting is followed up by a competent welding supervisor who is requested to keep a close check on the cost of the different operations.

There was also considerable discussion as to the relative merits of thermit and oxy-acetylene welding for repairing locomotive frames. It seemed to be quite generally agreed that thermit produced better results around the pedestal jaws, but considerable pains should be taken to properly preheat the frame and also to retain the heat around the "V." The use of asbestos lagging is now recommended as satisfactory for this purpose. Allowance should also be made for expansion in both the upper and lower rails of the frame. In case the fracture is in the top rail, the lower rail should be cut to permit equal expansion. One of the speakers also recommended heating the frame on the opposite side of the locomotive and then annealing the welded portion so that both sides would be alike.

The development of the otheograph for cutting out parts of locomotive frames, chains, hooks, etc., was also commented on. Cutting out parts by this method has effected a considerable saving over the old methods of forging. In cutting iron by the use of the torch, it is not necessary to preheat, but steel should be preheated and annealed afterwards.

Carbon and high speed steel

By J. H. Hill

Blacksmith foreman, Chicago, Burlington & Quincy, Aurora, Ill.

The tool temperer should be provided with facilities to closely duplicate the different hardening and drawing heats required by various classes of tools. Compare a forge fire, radiating heat from one direction, the heating of one tool at a time and a tool temperer's eye as the best gage, to a properly constructed furnace heating slowly and evenly a number of pieces in the same time and the correct heat ascertained by a pyrometer. It can be seen that such facilities are necessary to economical and efficient duplication of the tool temperer's work.

Our products are charged with the expense and we are held accountable for the results of these tools. It thus behooves us to become informed on modern tempering equipment so we can make recommendations and use our influence to get these facilities.

Keeping the tool temperer informed as to the results of service obtained from the tools is necessary to attain high efficiency for the most modern equipment. It is in no way a self-operating device, but it will, with the co-operation of the tool foreman and the tool temperer's knowledge, give the results for which we aim.

The hardening or refining heat is of the most importance, for it is the base and a one hundred per cent tool can not be produced unless this part of the work is done correctly. There are three different methods used in ascertaining the correct hardening heat, all of which are good, and in a measure depend upon the mechanical equipment. If the furnace is equipped with a pyrometer, reduce the heat of the furnace below the hardening heat. Place the pieces in the furnace and have the thermo couple arranged so that the slightest change in the heat of the piece will instantly show on the pyrometer. Then set the regulators so that the heat is slowly advanced and when the hardening heat is reached a slight pause is noted on the pyrometer which indicates the hardening heat. Small furnaces are manufactured which are sensitive enough for this particular work.

The second method is the magnet and it is used in the following manner. Couple the magnet to a light socket or to a battery system. The magnet is balanced on a rod so that the back end is slightly heavier than the front end or magnetic point. Reduce the heat of the furnace below the hardening point. Place the piece in the furnace and set the regulators so as to obtain a slow rising heat. Then apply the magnetic point to the piece being heated. When the heat gets close to the correct hardening heat, the piece will cease to attract the magnet and the slightly heavier back end will cause it to change position, which is a notification to the operator that the hardening heat has been reached.

The third method is one that has been used for many years and is as reliable today as it ever was and is as follows. Turn a test piece one inch round and about three inches long. Then nick on one side and temper at the lowest heat which will make the piece file proof. Fracture and examine the grain which will, with practice, enable the tool dresser to determine if it has received the correct heat. It will further enable him to pass judgment on a tool that has broken in service and if the grain is right, prove that some other than incorrect hardening is the cause and thereby save breakage of future tools used for that particular purpose. The correct time required for heating has been worked out in several ways and the following general system gives the best results: The correct hardening heat of a tool, we will say, is about 1500 deg. F. The regulator of the furnace is set to maintain that heat. Then lay the tool on the floor of the furnace and move it every few minutes, noting if the spot on which it was lying is darker than the rest of the floor. If the floor is darker, the tool is not heated through, but if the spot shows the same color as the rest of the surface, it is heated through. It should be left to soak five minutes to each inch of thickness after the spot on the floor is gone.

Drawing the temper of tools made of carbon or high speed steel is done to relieve them of hardening strains, which are set up throughout the tool. The drawing heat, to be efficient, must be through the entire piece so that the core as well as the outside wall is benefited. This is also a point to be considered in examining fractures.

An epidemic of breakage occurred in the fillet of the shank of beading tools. Examination of the fracture of the tool showed the core to be file proof. The outside surface, however, could be readily touched by the file. This proved beyond doubt that the tools had been overheated in tempering and a quick drawing heat had been produced. The color on the surface had not

benefited the core. As a result we always check the drawing heat in oil.

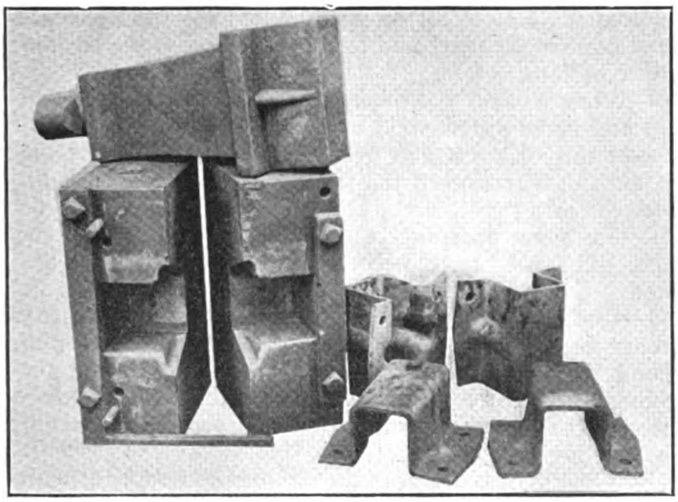
One other point on the drawing of temper that we endeavor to make is to draw at the lowest heat which will satisfactorily answer our purpose, for the lower the drawing heat the harder the tool. It is the rule rather than the exception, that the harder tool will give the best results.

We have handled a large amount of carbon and high speed steels and most always get good results by following the instructions given us by the steel men. In 1919, when it was hard to get tool steel, our tool room foreman had 12 sets of dies and punches to make for forming copper ferrules for flues. These dies had to be gotten out in a hurry and as we had no tool steel from which to make them, we made them out of scrap pieces of Nychrome steel side rods. These punches and dies when properly heat treated have made thousands of copper ferrules in the past six years and are still in good shape.

Drop forging

By F. P. Deissler
Blacksmith foreman, Bessemer & Lake Erie, Greenville, Pa.

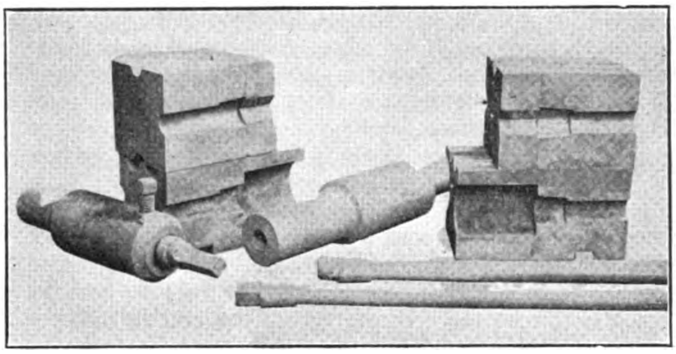
Concerns that have made a business of drop forging are, of course, better equipped with machinery and capable men to work out their dies. This is important, for if your dies are not right, you cannot get the required results. The average railroad blacksmith shop does not have drop hammers because of not having enough work to justify the installation of such a tool, but practically all have steam or power hammers of some description, or at least should have. We do considerable work that we call drop forging in our shop, but we use the pocket die method and get fair results. The dies used are not expensive and doubtless the results obtained are as good as can be done without a drop hammer.



Dies for forming stake pockets

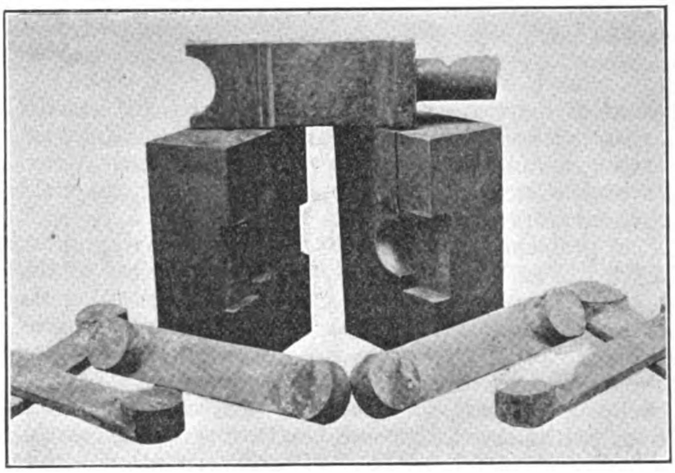
We make our own dies in the blacksmith shop, except shaping the edges and drilling. We first make a master piece of the article we want, taking a little care to get it as nearly the exact shape as possible, except in thickness which we make 3/8 in., or more, too large. We then forge two pieces of steel so as to have at least 1 1/2 in. thickness at the bottom of the impressions and enough larger than the impression so as to have at least 2 in. on all the edges. We then reheat to a good soft heat, clean all the scale from the faces and place the master piece between these two blocks and press or drive them under the hammer until the edges come close. We then take them to the machine shop and have the faces planed off so the impression will be the correct depth in each, the master piece being thicker than the finished piece.

This brings the edges of the impression to a good edge; otherwise they would draw in and leave too much opening at the edges. We then have them planed to a given size on the outer edges, placing a finished piece between so as to be sure that the impression and outside edges are correct. We then make a band, the size of the blocks and about 2 in. higher than the bottom one, so as to receive the top block which should be loose enough so as to enter freely and guide it to the proper position. The impressions should have about 1/16 in. chipped back about 1/2 in. or 3/4 in. for splash.



Dies and headers for forming taper crown bolts

For work which is done from the end of the bar, a slot can be cut in the band for an opening to receive the bar. Where the piece is made from a block this is not necessary. There is one thing to remember, that the stock should be of the proper amount and shape and good soft heats used. I believe that more failures come from these two reasons than any other. After passing the piece through this tool and allowing it to cool, the fin or splash is trimmed cold. The trimmer is a piece of hardened tool steel the shape of the piece which is being worked. This block is placed on the hammer die and the forging is driven through.



Dies for forming locomotive spring hanger ends

Discussion

Drop forging is not a game to play with for it is a difficult problem to study, especially with the idea of reducing costs. It was generally agreed that dies used

in shop forging work should be made of special steel and not from scrap material, such as old car or locomotive axles. Some scrap axles will harden, while others will not, so such material is not always dependable for making dies. Fine steel usually stands the wear pretty good but it is not as good as steel made especially for die blocks.

Drawbars and pins

By Alexander MacDougall
Blacksmith foreman, Bangor & Aroostook, Derby, Maine

We have three kinds of conections, namely: the solid bumper, wedge and spring. We find that the solid bumper and wedge are hard on the drawbars and pins. The spring bumper is applied as the locomotives go through the shop. The slack is taken up at the engine house by putting a plate between the bumper, or back of the spring. These are removed as the locomotives go through the back shop and the bar is made to the proper length. If the holes are worn oblong, they are upset to the proper size and if the metal between the hole and the end is too thin, a piece is welded on the end to make it the proper thickness. The solid bars are made of hammered iron and the pins of machinery steel. Our latest locomotives are equipped with two bars placed side by side.

For some years we have been making drawbars of ½-in. tank steel. The plates are cut the right width to leave plenty of stock around the hole, the center is cut down to 5 in. with the acetylene torch and sheer. Enough plates are used to make the bar the right thickness and a "U"-shaped yoke of 1-in. round iron is placed around the center, with a piece of 1-in. by 2-in. iron clamped across it, double nutted and screwed down tight. The drawbar is then sent to the machine shop to have the holes drilled.

This makes a good flexible bar and so far we have had no failures. When it is necessary to shorten them, the yoke is taken off and each leaf is shortened and put together again. Very little slack is allowed on the Bangor & Aroostook; if there is ⅛ in. slack, it has to be taken up.

Discussion

Some of the speakers reported that it was the practice on their roads to use scrap car axles for this purpose. It was generally agreed, however, that the carbon content of the steel in car axles was too high to make satisfactory drawbars.

The problem of reclaiming drawbars having worn holes led to some discussion as to the advisability of this practice. Some roads make a practice of upsetting the drawbar on a die that extends up the side of the head in order to prevent the hole from being flattened during the upsetting process. Other roads make it a practice to build up the hole with oxy-acetylene welding. It was contended, however, that the heat evolved in the welding process tended to crystallize the metal and thus weaken the drawbar. It seemed to be the concensus of opinion that it was poor practice to weld a liner inside the hole.

Frame repairing

By P. T. Lavinder
Blacksmith foreman, Norfolk & Western

We formerly used the electric welding process exclusively in repairing broken locomotive frames, with the exception of the smith shop forge welds. The electric welding process has been replaced by the oxy-acetylene when welding frames in position on the locomotive. When a frame is removed from the locomotive and welding is necessary, we recommend that it be forge welded in the smith shop.

The following is a complete record of the results obtained on the Norfolk & Western during the past 17 months by the various welding processes.

Kind of weld	No. welds made	No. welds failed	Per cent failure
Oxy-acetylene	757	28	3.7
Smith shop forge	12	0	0
Electric	58	14	24
Total	827	42	5

In making oxy-acetylene welds on locomotive frames we proceed as follows:

1—Remove all parts necessary to provide expansion and to allow free access to both sides of the frame.

2—Make sure the frame is in line and properly blocked so that it will stay in perfect alinement during welding.

3—Tram the frame, using a one-piece tram and have the tram marks, if possible, not closer than 12 in. to the break.

4—Vee out the frame at 45 deg. angles all the way through, from both sides, using the oxy-acetylene cutting process.

5—Spread the frame for expansion, allowing ¼ in. to ⅜ in. according to the size of the frame.

6—The scarfs of the vee must be chipped or brought to a red heat and cleaned with the welding torch to remove all burnt metal before starting the weld.

7—Use a plate under all vertical welds; the plate should stand away from the frame ⅛-in. to allow perfect fusion at the bottom of the weld. When the weld is completed remove the plate and finish smoothly on the bottom with a welding torch.

8—When a weld is broken always cut out all the old weld and make a new weld on good sound metal.

9—If this makes a gap over 2-in. in the center of the vee, cut out a section of the frame not shorter than 6 in. and weld in a new piece.

10—In some locations a new section is welded in where old welds have been made, or where flaws are found.

11—On frames 5 in. by 6 in., or larger, a preheating furnace is used and a charcoal or coke fire is carried around the frame at the point of the weld during the welding. When the weld is completed the furnace is removed and the weld is wrapped with asbestos to permit slow cooling.

12—On smaller frames, the frame is wrapped with asbestos for a distance of 12 in. on each side of the weld to hold the heat during the operation. When the weld is finished, it is wrapped with asbestos to permit slow cooling.

13—When a weld is started it must be continued and never allowed to cool down until finished and must be welded from both sides at the same time.

14—All welds are reinforced not less than 20 per cent when clearance will permit.

15—The spreader is generally removed immediately after completing the weld, but good judgment must be used in this matter as there is sometimes danger of upsetting if the spreader is removed too soon.

16—Successful frame welding will depend upon two main factors; namely, proper preparation and competent welders.

We attach a record plate to all frame welds showing the engine number, name of the welder, kind of weld, place and date welded. The plate is numbered showing the number of times the frame has been welded in the

same location. A report is then made to the office of the superintendent of motive power, giving the same information, and in case a weld fails, the record plate is removed and sent to the office of the superintendent of motive power, thus making it possible to keep a complete record of all frame welding.

Reclamation

By Walter Constance

Blacksmith foreman, Chesapeake & Ohio, Barboursville, W. Va.

The Chesapeake & Ohio has no large central shop for reclamation. Most of the articles are usually reclaimed in the general shops. Brake beams are repaired at six different points. Couplers are straightened, truck sides and body bolsters are repaired, all-steel car parts and even steel center sills are reclaimed, for the most part, at the large central shops at Huntington, W. Va. All track tools for the entire system are brought to Huntington by the supply train. Special dies for Bradley hammers are used to make chisels, spike mauls and picks. All tamping ends for tamping picks are upset upon 2½-in. Ajax forging machines. We can make from 1,000 to 1,200 tamping ends in eight hours, using one forging machine man and one additional smith to do the work of hardening. In cases where the tamping picks are too short to upset, they are made into clay picks, one end being built up by welding where necessary.

Tire steel is used to make blacksmith tools and some kinds of draft keys. Electric welding saves much of the material around the shops that formerly was scrapped.

Discussion

The reclamation of scrap car axles was discussed by a large number of those present. It is practiced to a limited extent by a number of roads throughout the country, but only one railroad shop, located in the middle west, seems to have taken up this work extensively. All of the work for reclaiming car axles for the entire system is centralized at this shop. During the past ten years some 30,000 scrap axles have been returned to service at the annual saving estimated at $40,000. Worn axles are returned to service as a standard axle of the next smaller standard size.

The scrapped axles are placed in a furnace and heated for half their length. When the axle reaches the desired heat, it is swung to a 4,000-lb. double-frame steam hammer on a jib crane. The end collar or "button" is drawn down to size by three or four blows in the smaller groove of the hammer die and the wheel seat collar is drawn down to the size of the wheel seat in the larger groove. The axle is then returned to the furnace, the other half is heated and the above operations repeated.

If the axle is slightly bent, it is straightened and the length between the fillets at the inside of the journal is gaged for correct length. If the axle is too short, it is drawn slightly at either side of the center so as to restore it to the required length. After the end collars have been upset and all forging work completed, the axle is annealed, allowed to cool overnight and is then forwarded to the lathe department for turning.

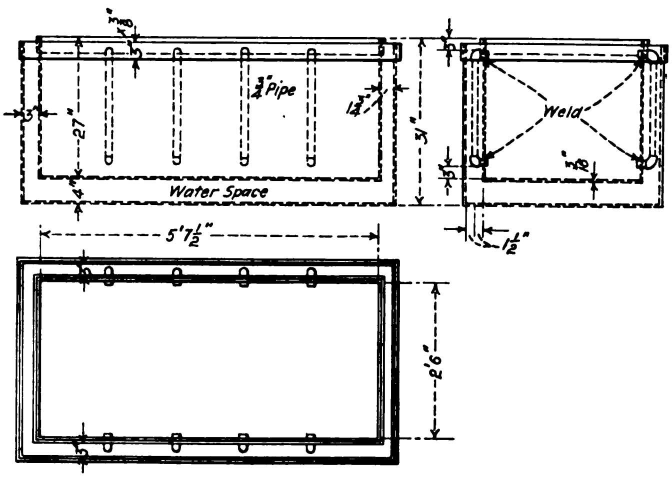
Spring making and repairing

By Geo. H. Corcoran

Blacksmith foreman, Grand Trunk, Battle Creek, Mich.

Springs received from outside points have the bands removed. All broken and worn leaves are replaced with new steel, the springs are tested and returned to service. Springs removed from locomotives in the shop for repairs are sent to the spring department where they are inspected and if found defective are repaired. Springs found to be all right have the proper height and carrying test load stencilled on them and are then returned to service. Spring leaves are heated in a fuel oil furnace to 1600 deg. F., formed on a Ryerson leaf forming machine and cooled in a tank of Houghton's Soluble No. 2 quenching oil. They remain in this oil until cooled down to 900 deg. F., or what is called a flash temper, and this leaf is used in the forming machine for bending the next leaf in shape.

The oil tank is placed in a larger tank which is surrounded by running water. It is equipped with 8¾-in. pipes, four on each side of the tank. These pipes run out from the side of the oil tank, about 2 in. from the top and down through the water and again into the oil tank near the bottom. When a hot leaf is placed in the oil, the hot oil comes to the top, flows out into the side



Spring tempering vat

pipes, down and into the tank at the bottom. By this time the oil is cold and it automatically feeds back into the tank and never requires any attention. We have tested the oil for several weeks and the temperature was found to be between normal and 130 deg. F., which was the highest in eight hours of constant use.

The spring plant is equipped with a hydraulic spring bander, hydraulic spring band remover, combination punch and shear, spring tapering rolls, nibbler and trimmer, a pneumatic spring tester and three furnaces for heating and tempering spring leaves. All the spring leaves are painted with heavy oil and graphite before banding. Some of our spring bands are forged and welded and some are of cast steel which costs about one cent per pound less than we can forge them. We have had bood success with them. Weldless bands are used for tender and coach springs.

The writer recently visited one of the largest production spring plants in the world, which specialized on a certain class of springs. Spring leaves are fed in one end of a furnace and come out the other end, heated to 1500 deg. F. They are then placed in a spring forming machine which revolves in a large vat of quenching oil. The forming machine has four or five arms. As a hot plate is put in the machine, it clamps it to a form and is held fast to the shape while the machine revolves in the oil and cools it off. Each leaf in the spring has a special machine form and oil tank. All leaves are made at the same time so that there is no fitting of the spring plates as all leaves are a perfect fit. After the leaves are hardened, they are placed in a nitrate of soda bath and heated to 900 deg. F. and held at that temperature for 15 minutes and then taken out.

All spring steel received at this plant is tested by

metallurgists before any is unloaded out of cars. Special machinery is constantly in use for testing completed springs for load endurance and breaking point and records are kept of these data. Brindell tests are made and a hardness of from 387 to 418 is required.

There is no doubt but that a great change is about due in railroad shops for making springs in a more scientific way. A few roads are making them that way now, but not many. Most of us are depending on our spring makers and while we are fortunate in having good spring makers, we do have to rely on their good judgment for getting good springs and we know that what they do has a certain "chance" element. When we have the equipment to make a spring scientifically, step by step, then we will feel that we have made a spring that can be depended upon. While we know that some scientifically made springs do break, they are a thousand times more reliable than when made by "chance."

Proper heat treatment is an important part of spring making. Accuracy in the proper degree of heat for hardening and drawing back is vital to the life of a spring. Electric furnaces are most accurate for controlling the temperature as they will keep within five degrees of any desired heat, thus making it possible to give every leaf in the spring the same heat treatment. It is not so with oil because of lack of uniformity. One tank of oil will be heavy, another light or medium. One oil will burn clear and free, another dead and smoky. With these and varying degrees of heat, it is impossible to keep a furnace at a fixed temperature in order to obtain constant results.

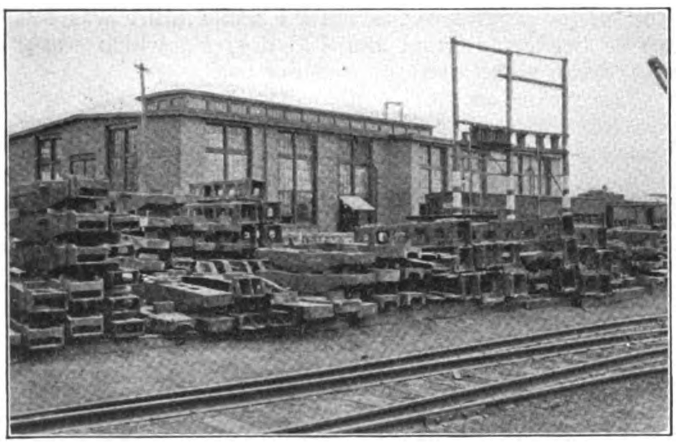
Vanadium spring steel will also probably come into more general use. It was tried out some years ago on a number of railroads but it did not make any better spring than the carbon spring steel. Today with a better understanding of the right heat treatment, there is no doubt but that it will make a much lighter and better spring than the carbon spring steel.

Welding in railroad shop practice

Equipment and methods used in Santa Fe shops at Albuquerque, N. M., insure dependable work

WELDING practices employed in the Santa Fe shops at Albuquerque, N. M., are probably as good a representation of best railroad practice as can be found. The shops were built about two years ago and accordingly the equipment used is for the most part new. On the other hand two years have elapsed since it was installed and in this time means have been devised for using the equipment to best advantage.

The shops include roundhouse, car shop and back shop.



A pile of truck side frames, truck bolsters and body bolsters reclaimed by welding

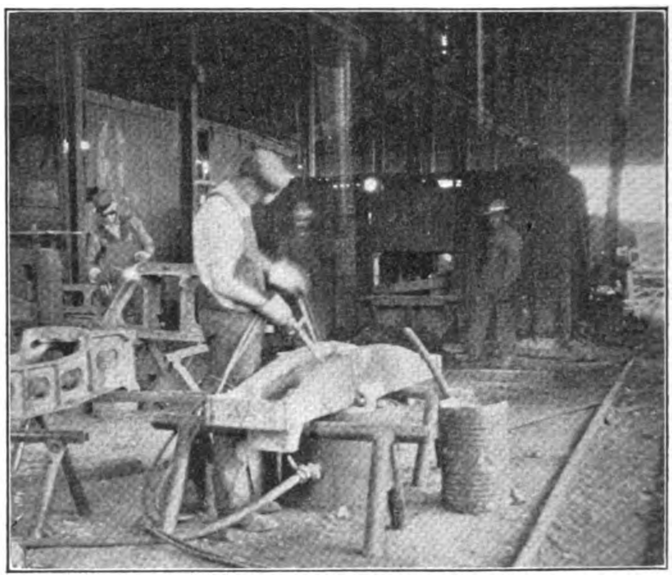
The back shop is now turning out something over 300 classified repairs a year and normal annual output of the car shop is 1,200 heavy car repairs.

Equipment

Both the gas and electric process are used, the gas being used for welding and cutting, the electric for welding only. The electric arc welding equipment consists of six portable electric welding machines in back shop, two in roundhouse and one stationary type in welding shop, which furnishes current for four operators.

The flue welding shop is equipped with one small and one large electric flash or butt welding machine, the small machine being used for safe ending flues from two inch to two and one-quarter inch diameter; the large machine is used for all flues of larger sizes.

There are also two portable electric arc welding machines in use at the car department for welding of car castings.



Welding shop in the car department, showing the preheating forge, horses for supporting the castings and the annealing furnace

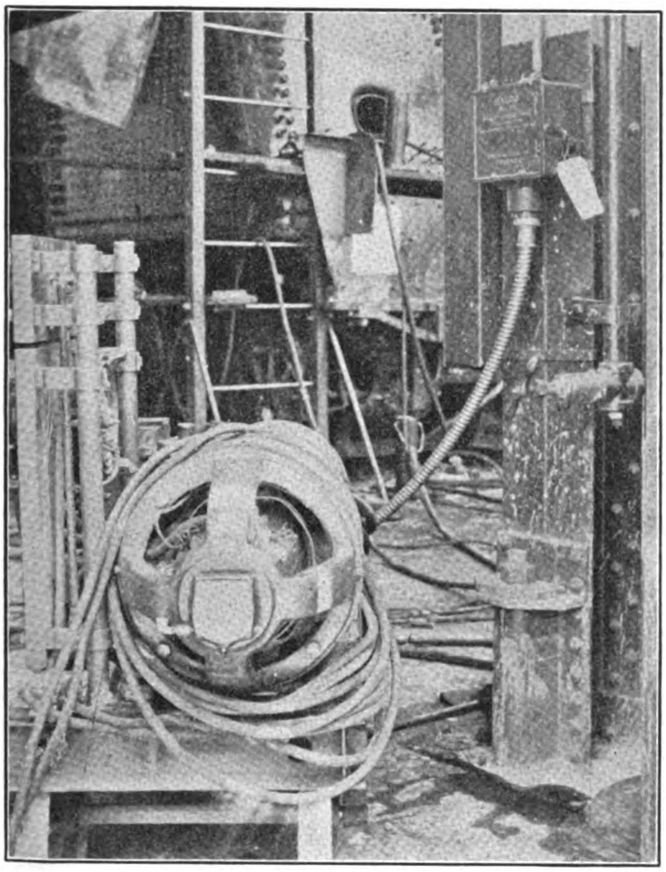
All car repair work is done in the car shop or yard. Small locomotive parts that can be moved easily are taken to the welding repair shop and the welding of large parts is done in the back shop.

The car shop, roundhouse and back shop are piped for both acetylene and oxygen. The acetylene is carried at a pressure of from 7 to 8 oz. in a 4-in. line with smaller

laterals. A 2-in. line and a pressure of 55 lb. is used for the oxygen. The oxygen is purchased in cylinders. A number of cylinders, connected through a manifold, supply oxygen to the pipe line. Practically all of the acetylene is generated in a small generating plant in the shop and supplied to the pipe line from this plant. A few cylinders of acetylene are kept on hand for use on a portable outfit that can be taken to outlying points.

In the locomotive department there are about 200 gas stations or outlets and there are 87 on the repair tracks and in the car shed. On the erecting floor the gas stations are located in the pits and on the machine side they are placed on the columns. The welding and cutting torches are fitted with 50-ft. hoses.

The electric welding sets are operating from a 230-volt direct current circuit in the back shop and roundhouse and from a 440-volt, 3 phase alternating current circuit in the car shop. On the erecting and machine tool floors



One of the portable arc welders in service

the welding outlets are located on the columns about 6 ft. above the floor. The receptacles have an interlocking mechanism so arranged that the plug cannot be inserted or removed from the receptacle unless the switch is open. These outlets are also used for the operation of portable lathes and motor driven cylinder boring bars.

The motor of each welding set is provided with a six foot lead or armored cable and a plug for connecting to the power supply outlets. The lead is made short so that the set must be close to the column when it is connected and cannot be set so as to obstruct the aisles. The generators are provided with cambric insulated, braid covered welding leads from 50 to 70 feet long.

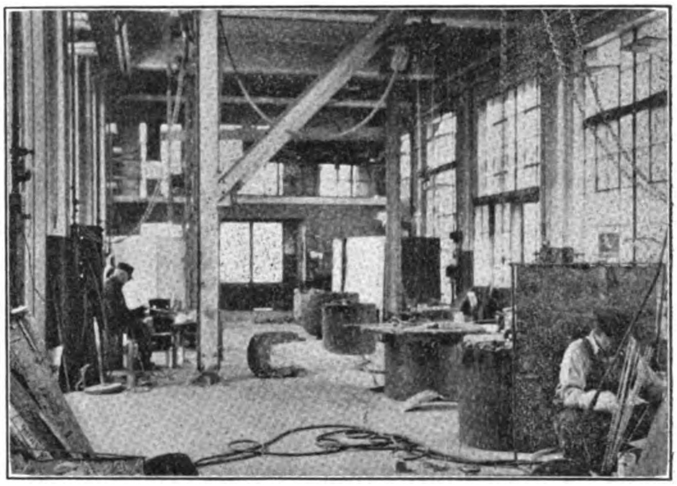
Car department welding

Welding has been applied to the work of the car department on a large scale with surprising results. The bulk of the work done consists of welding cracked truck side frames, truck bolsters and body bolsters in accordance with A. R. A. rule 23.

The sections to be welded are first inspected to determine whether or not the fractures are within the welding limits. Before a weld is made the piece is cleaned with a sand blast. The crack is V'd out with the cutting torch and the slag chiped off with a cold chisel and hammer. The weld is then made either with the electric arc or the gas welding torch.

When the torch is used, the member to be welded is placed over a pre-heating forge with the ends of the section on horses. The horses were built by the welding process from 3-in. pipe. The forge is made of a piece of 24-in. pipe about 20 in. long. About 6 in. from the lower end there is a circular grate with a piece of ¼ in. pipe projecting through the center. The pipe is supplied with air from the shop air line and the amount of blast is regulated by a valve just outside the forge. The forge burns coke and is used to heat the part of the casting on which the weld is made. This procedure has been found to improve the character of the weld and to reduce the amount of gas required to make the weld.

After the weld is made the casting is picked up by a 1½-ton chain hoist on a post crane and placed in an an-



The welding shop

nealing furnace. The furnace has a capacity of four castings and burns oil. The castings are heated to a temperature of from 1,400 to 1,500 deg. F. after which they are removed and allowed to cool. They are then given a final inspection and replaced in service. All truck side frames and bolsters which are welded are marked to show the shop in which the weld was made, the operator who did the work and the date the work was done. Thus AQ-6-3-5-25 would signify that the work has been done at Albuquerque by welder No. 6 on the fifth of March, 1925.

The normal output of the car shop is about 100 cars per month. The savings effected by welding in this department alone, not considering scrap value, have been shown to be $6,000 a month. The welding is done by 5 gas and 2 electric operators.

Locomotive department welding

The work done by the locomotive department has so many ramifications that it would be difficult just to make a list of the jobs done. For this reason only a few of the outstanding or unusual jobs are mentioned here.

The method of applying shields to superheater units or tubes, is one operation, which has proven to be highly

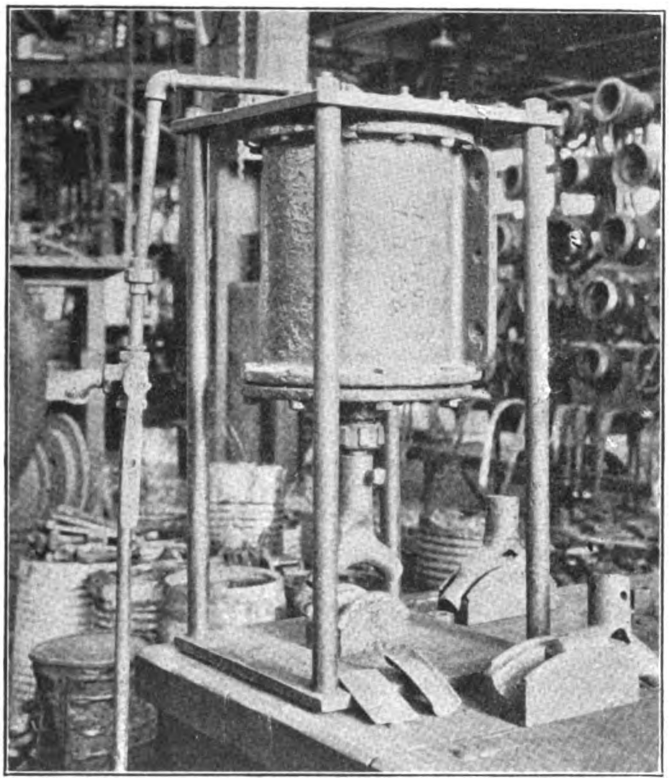
profitable. There are two places in the curved-up ends of the tubes where they are cut by cinders. To prevent damage from this source a piece of No. 14 or No. 16 steel plate is formed so as to fit the outside of the tube, and is placed over the section that is subjected to wear. It is held in position by four tack welds at the corners. The protecting plates are formed in a die, operated by an air cylinder.

The feed and elevator screws on stokers when worn by the action of the coal are built up by either the gas or electric process. After the edge of the screw has been built up it is left rough as welded. The welded edge is sufficiently accurate for the purpose and the surface of the weld withstands the action of the coal effectively. Stoker rack teeth are replaced with electric welding and machined after welding.

These and many others can be cited as examples of the importance of welding in the locomotive department.

Welding shop

Portable locomotive parts which require welding are taken to the welding shop. It is housed in a one-story building, 30 ft. wide by 90 ft. long. There are ten gas stations in the building and four electric welding outlets. Current for electric welding is supplied by a four-operator stationary welder mounted on a platform or balcony at one end of the shop. Polarized battery charging re-



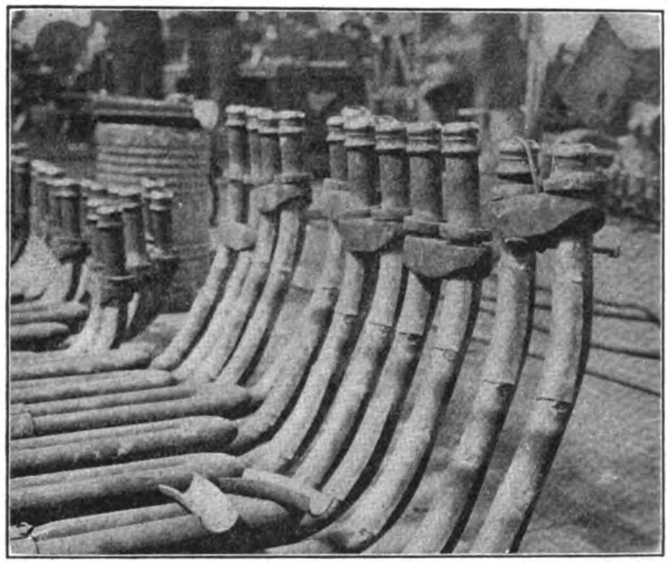
Press and dies for forming superheater reinforcing plates

ceptacles are used as welding outlets and 50 ft. welding leads and shop-made electrode holders are used.

The shop is also equipped with three-coke-burning, preheating furnaces, two 1½-ton and two 3-ton air operated jib hoists, six welding tables, a heavy vise, a cutting table and an exhaust hood for brass welding. The welding tables are 22-in. high and have legs made of 3-in. pipe. Originally the tops of these tables were covered with fire brick, but a piece of ¾ in. boiler plate was found to be a more satisfactory top and a piece has been laid on top of the brick on each table. The cutting table consists of a large iron kettle across the top of which have been placed several pieces of scrap boiler plate so as to form a sort of grill on which the material is cut.

Testing operators

In order that officials in charge of welding and the welders themselves may know what kind of welding is being done from month to month, it is the practice of the Santa Fe Railway to have each welder furnish a test plate monthly. The manner in which this plate is made and tested was described recently in a paper by E. E. Chapmen, engineer of tests and H. H. Service, supervisor of welding equipment, presented before the Chicago section



Some reinforced superheater units

of the American Welding Society. The procedure is as follows:

Secure two pieces of boiler steel ⅜ x 2½ x 9 in., bevel one end of each to form a 90 deg. angle between them, place the two plates in a convenient position for welding with 3/16 in. opening at the bottom of the "V" and make the weld from the top side only, reinforced a maximum of 20 per cent over stock size on one side only, if welder desires this much reinforcement to produce his best weld.

It will be noted that in this test plate the weld is allowed to be reinforced 20 per cent over stock size, more than that is milled or ground off, and plate to be welded only from one side, in order that the welder can approximate the condition of welding a side sheet or its equivalent in a firebox. The welder is instructed not to forward any weld for test unless he is satisfied that it is the best he can make, and representative of the work he does. These welders are then rated according to the percentage strength of their welds which is based on the thickness of the original stock, and an ultimate strength of 60,000 lb. per square inch. It is the desire to have welders stimulate actual working conditions as nearly as possible, and it is also endeavored by the foreman to have the welder complete his work at the original heat and avoid the plastering over of metal incident to reworking and consequent weakening of the original weld. From the test data thus obtained the foreman has sufficient information at hand to judge the welder's ability to produce good work and it will justify him taking proper steps for keeping the welding up to a high standard by correcting the faults or assigning only the men who are able to make satisfactory welds to the more important welding operations.

Tests have also been made to determine the relative efficiency of welded specimens to the original stock, under vibration or alternate bending, but this is a comparative

proposition and not one that can be used as a regular control.

Welding efficiency

An analysis was made of specimens tested for the years 1920 and 1921 to show the average efficiency of welds produced by welders having different years of welding service and the results are shown in Table I.

TABLE I

Years service as welder	Welded specimens tested: Gas	Electric	*Efficiency of weld—per cent: Gas	Electric
Less than one	195	147	75.8	90.6
One	93	81	89.2	93.2
Two	177	131	85.8	92.9
Three	78	72	84.4	95.2
Four	47	10	90.6	96.9
Five	27	..	96.7	....
Six	4	6	98.3	101.0
Seven	3	9	74.6	94.9
Eight	16	..	82.4	....
Nine	7	..	89.6	....
Total	647	456	Ave. 86.7	95.0

* These efficiences are values based on a tensile strength of 52,000 lb. per sq. in., the minimum value allotted in specifications for firebox steel.

It is noted that for the seven and eight years welding service the value showed a great deal below the average which was due to a poor welder working in these two groups, but the indications are that the longer the service the greater the skill shown by operators. It will also be noted from this tabulation that for strength alone the electric welding shows up better than the oxyacetylene welding. However, for the year 1923, a check of this relation shows that due to improvement of the kind of metal used for welding with oxyacetylene the results of the latter are about on a par with the electric welding for strength.

The results obtained in four of the largest shops and in four of the largest roundhouses of the system are shown for the last three months of the year, October, November and December, 1924, in Table II.

TABLE II

Shops	Welded specimens number tested: Gas	Elec.	*Specimens broken outside of weld, per cent: Gas	Elec.	†Efficiency, per cent specimens broken in weld: Gas Min.	Gas Ave.	Electric Min.	Electric Ave.
Topeka	29	46	24	24	77	101	75	96

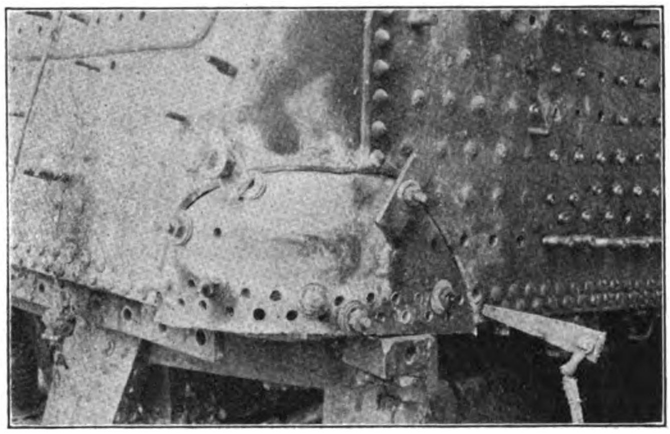
*This column also includes welds which showed 60,000 lb. per sq. in. tensile strength.

†Efficiency based on firebox steel, 52,000 lb. per sq. in. minimum tensile strength.

It will be seen from these figures that a butt welded seam with a maximum reinforcement of 20 per cent of stock averages well above the 45 or 50 per cent efficiency allowed for single riveted seams.

It is believed that for a large railway system like the Santa Fe too much stress cannot be laid on demanding of welders that they produce the proper strength of welds as shown by their test specimens so that both the management and the welders may know when they are doing acceptable work. The test pieces are returned to originating shops and the results discussed with the individual men by the foreman in charge. The system supervisor of welding equipment and service company representatives also go over the results of weld tests with the men and make suggestions for the betterment of the service.

From this it will be seen that the railway management exercises a systematic control over autogenous welding operations, especially as it concerns the welding of boiler and tank steel plates. This, of course, is only one phase of the rather extensive use of these welding methods and the periodic control can easily be exercised, but there is a very extensive amount of work where such control cannot be so applied. Problems, such as best procedure and method of welding locomotive frames, bolsters, couplers, cylinders, where heating and subsequent annealing are required, and many similar questions require careful service observations or comparative tests. The question arrives as to whether it is practical to weld certain kinds of material, whether hot or cold, whether to use cast iron or steel rods for welding material, and with such questions raised many tests have been conducted to increase the list of "Dont's" for anything not prohibited is assumed to be permissible.



A sample of welding in the boiler shop, showing the method used for grounding one side of the electric welding circuit

Material used

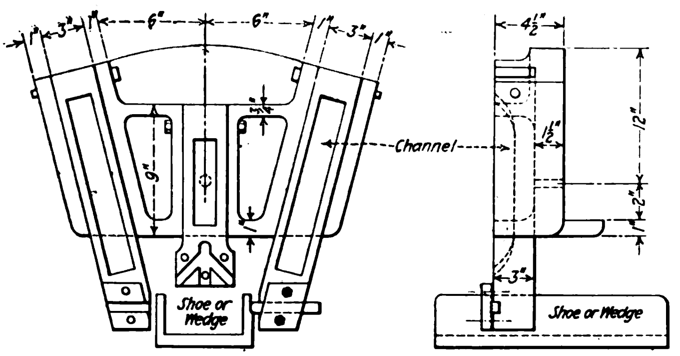
Norway iron welding rods are used for plugging holes and building up worn castings and steel rods are used for all work requiring high tensile strength. Steel electrodes are used for welding fire boxes, building up spots on locomotive frames and all steel castings, etc. Steel electrodes are also used for fire box work flues and for welding broken locomotive frames. Pure iron electrodes are used for flues and flexible stay bolt sleeves, etc. Tobin bronze is used for air pumps, and some cylinder work, but is not always used for repairing broken cast iron castings. Manganese bronze is used for building up rod brasses, galled places on main rods and worn spots on cross heads. Work that cannot be machined is ground down and finished with grinders.

Welding instructions

Data on new classes of work have been carefully compiled by the supervisor of welding equipment and in compliance with instructions from J. Purcell, assistant to the vice president in charge of mechanical matters, these data were issued as a standard pamphlet, designated "Oxyacetylene and Electric Arc Welding Folio," for the instruction and guidance of those who have direct supervision of welding in the various shops and roundhouses on the system. This welding folio is kept up to date by frequent revisions and as better methods are devised and better welding materials are developed, and tried out with satisfactory results, they are included in the folio.

Tool for planing shoes and wedges

A PLANER tool for finishing shoes and wedges on four sides in one operation is shown in the drawing. This tool was developed in the Finley shops, Birmingham, Ala., of the Southern Railway. It consists essentially of a back plate provided with three tool holders, pivoted as shown in the drawing. The shoes or wedges are ganged end to end the entire length of the planer platen. The cutting tools are held in place by means of

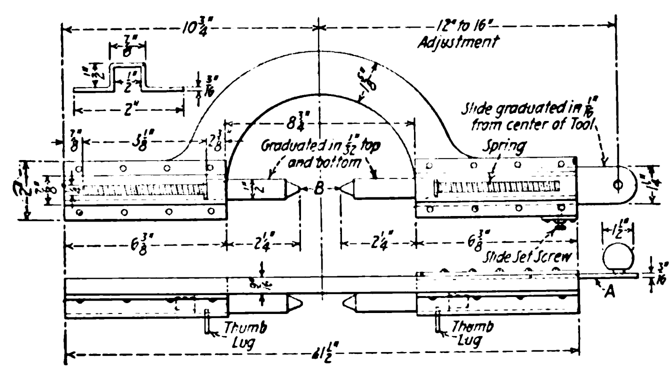


Planer tool for finishing shoes or wedges on four sides in one operation

clamps on the tool holders. They can be easily adjusted by partly loosening the clamp bolts and moving them toward or away from the work as desired. The back plate serves as a support for the cutting tool holders on the forward stroke, while on the return stroke, the tool holders are free to swing outwards on the pivot bolts. The center tool holder is constructed to hold three cutting tools so that both the inside faces and bottom can be planed at the same time.

Crank pin throw gage

THE throw of worn crank pins can be quickly and easily checked by the use of the gage shown in the drawing, as fast as they appear in the back shop for repairs. The ball center is attached to a graduated steel slide *A* which can be set for any desired crank pin throw. The 1/16-in. graduation marks of this slide are deter-



Gage for checking the throw of worn crank pins

mined by measuring from the center of the gage or from the center line equidistant from the points *B*. The points *B* are also on graduated steel slides which, when set, determine the exact condition of the throw of the pin.

For instance, if the crank pin throw should be 14 in., the ball center *A* is set to 14 in. The ball center is now placed in the axle center and the gage swung around until the points *B* are against the crank pin. If both of the point slides *B* read the same, it is known that the throw is correct.

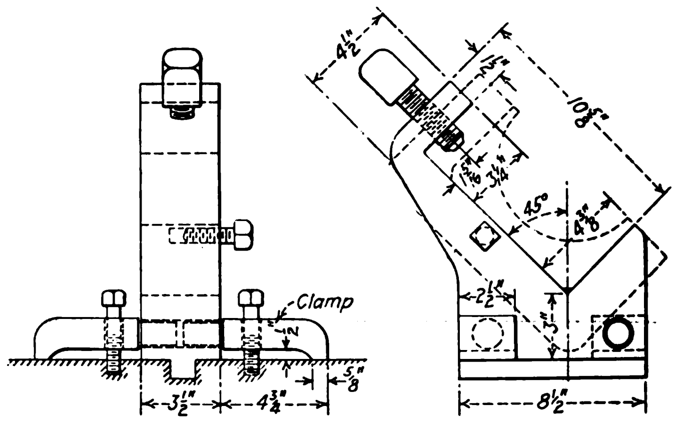
It has been found in the shops where this gage is in use that by frequent checking of the wheel quarters and pin throw, as well as careful tramming of the wheel centers from one another, troubles from broken side rods have been practically eliminated.

Milling grease grooves in main rod brasses

By E. A. Miller

THE drawings show a tool and jig for milling grease grooves in main rod brasses. This tool and jig have been adopted as standard on a large eastern railroad.

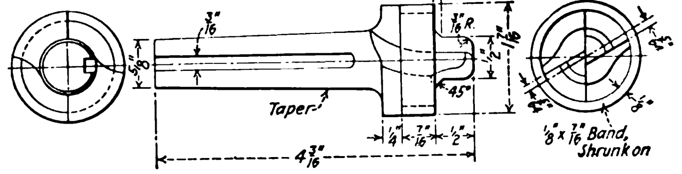
The shank of the tool is made with a standard taper.



Jig for holding main rod brasses on the shaper table when milling grease grooves

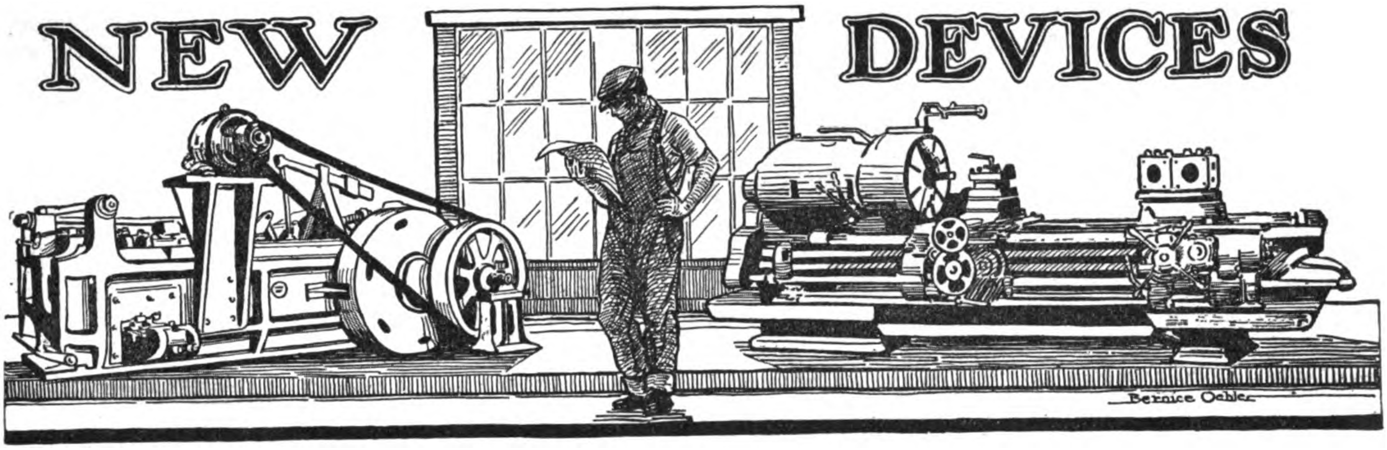
The cutters and shank are formed from one piece. A 1/8 in. by 7/16 in. band is shrunk into an offset on the head so as to provide a guiding edge for the operator to judge the depth of the groove. It also serves to reinforce the edges of the cutter. This band can be removed and narrowed down as the cutters become shorter from repeated grindings.

The jig for holding the main rod brass to the machine



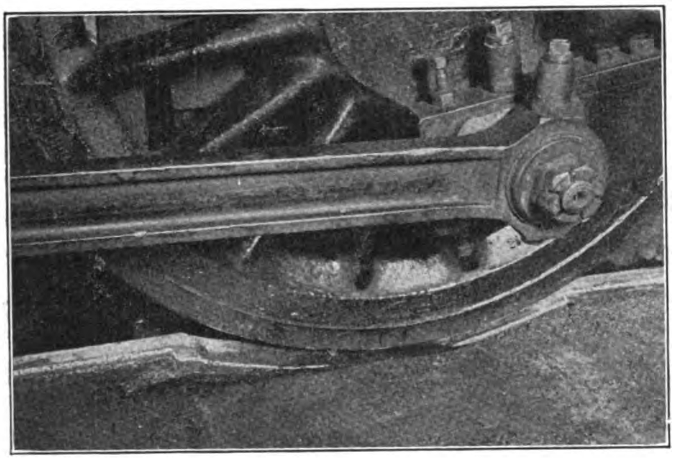
Tool for milling grease grooves in main rod brasses

table can be machined from a solid piece of wrought steel 3½ in. thick. It is clamped to the table as shown in the left hand view of the drawing. The main rod brass is clamped in the jig by means of a set screw. This arrangement facilitates the setting up and removal of the work in a short time.



Spring track assists in enginehouse work

THE Cardwell spring track has been developed recently by the Globe Railway Equipment Company, St. Louis, Mo., primarily to save time and labor in the enginehouse work. It operates on the well-known principle of the depressed track and consists of two steel rail castings, each five feet long and having a depression 3½ in. deep.

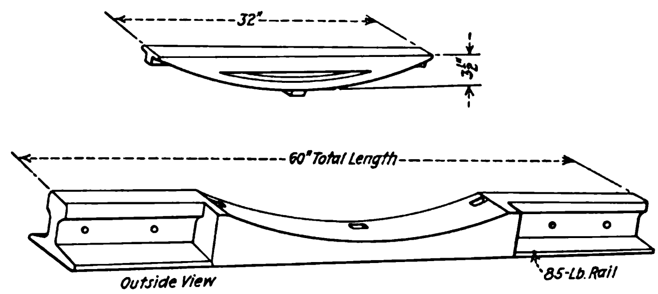


Right main wheel in the depression ready for the application of blocking over the driving box

The depression, shown in the drawing, consists of 32 in. of the circumference of a circle 10 ft. in diameter. The rail castings are inserted in one or more of the tracks inside the enginehouse.

Under normal conditions the depressions are closed by application of the removable segments which are held in alinement with the rail by lugs fitting in corresponding holes in the track castings. When necessary to perform such operations as changing engine truck wheels, shimming tires, renewing driving or trailer springs, etc., the removable segments are taken out. By blocking under the required parts of the spring rigging and running one pair of wheels into the depression, the weight can be taken off that particular pair of wheels without the labor and time involved in jacking up the locomotive, as would otherwise be necessary.

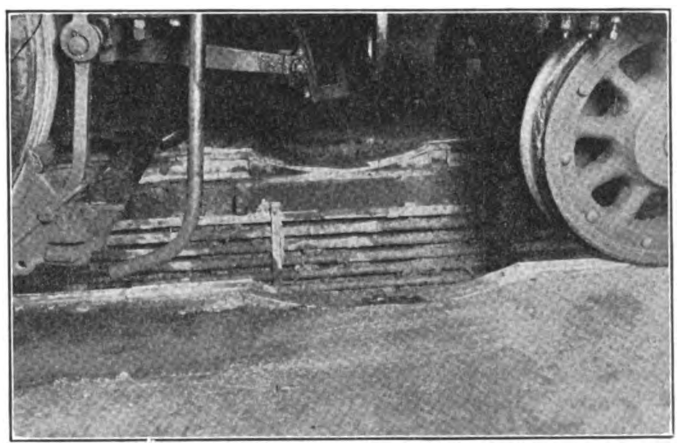
The Cardwell spring track has been in operation for several months and has proved to be entirely practicable. The provision of more than one spring track in the enginehouse, possibly one for every five or six stalls, will have a tendency to prevent delays to locomotives while a single spring track is occupied. The best location for the device is back of the driving wheel drop pit or engine truck drop pit, and, on all other tracks, far enough inside



A Cardwell spring track section

the house to accommodate the trailer wheels and still permit the enginehouse doors to be closed.

The following description of several operations using the Cardwell spring track will indicate the variety of work which can be performed with it: In renewing driving or



Removable segments can now be put in place and the track used like any section of level track

trailer springs, blocks are placed between the equalizers and locomotive frame or safety hangers in such a way that when the particular pair of wheels involved is run into the depression, the weight is removed from the driv-

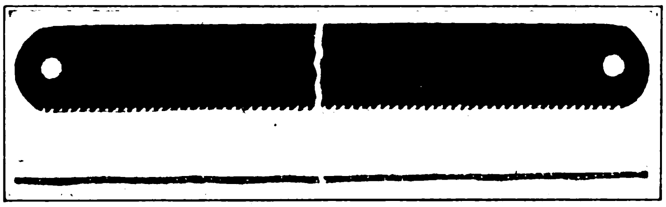
ing box or trailer housing, as the case may be. The new spring is then applied and the locomotive moved so as to pull the wheels out of the depression, the spring change thus being accomplished without any jacking up.

In cases where engine truck drop pits are not available the spring track can be used for changing either or both pairs of wheels in a four-wheel engine truck. The method of procedure in this case is to take down the truck pedestals in question and chain up the engine truck frame. The front driving wheels are then run into the depression and blocking applied between the front driving boxes and the locomotive frames. Movement of the locomotive wheels out of the depression raises the front of the engine and the front truck frame so that the defective truck wheels can be rolled out and others applied. The locomotive front end is lowered and the weight put back on the engine truck by the reverse operation.

In addition to facilitating all classes of spring work and changing engine truck wheels, trailer or engine truck brasses may be changed by means of the spring track. The effect of the device is to save nearly one-third of the time and labor involved in jacking up locomotives when necessary for one reason or another to remove the weight from various parts of the spring rigging.

Improved power hack saw blade

A POWER hack saw blade known as the wavy-set has recently been placed on the market by the Henry G. Thompson & Son Company, New Haven, Conn. The trade name has been derived from the method of setting the teeth in the blades. This method is intended to give additional strength to the teeth and to make them more nearly alike in shape. It is said, with this form of setting, that it is quite practicable to use a 10-pitch blade on thin-walled tubing.



Notice the wavy appearance of the cutting teeth of the Milford hack saw blade

The characteristic setting of the teeth is accomplished by passing the heated blades through a series of suitably shaped rollers that bend the serrated edge first in one direction and then another, imparting to the edge a wavy appearance not unlike that of a thin circular milling cutter. The waving extends away from the edge far enough so that each tooth is assured the support of the full thickness of the stock, and the abrupt bend caused by the usual method of setting is avoided, which is a desirable feature.

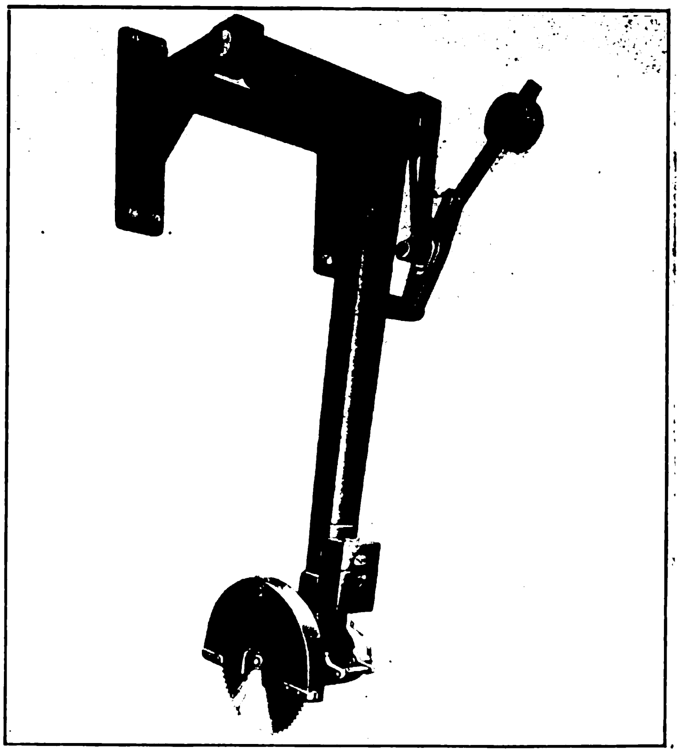
Overhead mounted wood swing saw

A SWING cut-off saw which may be mounted either on a wall or ceiling, designed for safety, lightness and ease of operation, has recently been placed on the market by the Oliver Machinery Company, Grand Rapids, Mich.

The hanger bracket is cast in one piece with a 37-in. base, machined parallel to the trunnion axis of the swinging arm. It is so designed that the machine may be mounted either on the wall or ceiling without any fitting other than placing the weight arm in the proper position. The main frame is of the rigid, single arm type, cored in a U-form. It swings on ground pins of large diameter. The counterbalance is so constructed as to give the operation of the arm an easy and lively motion. It acts on the arm at a point about one-third of the way down from the trunnions. In this location, it takes less weight to throw the arm back to the starting position and a lesser effort for the operator to throw it forward. The slot in the weight arm is shaped to bring the saw to its starting position.

The motor arbor housing is tongued and grooved to the frame with a 2-in. vertical adjustment allowed for setting up or to provide for a 4-in. reduction in the size of the saw. The housing is of a three piece rigid construction, with the end pieces of cast aluminum. The stator of the motor is mounted in the housing. The shaftless rotor is mounted on and keyed to the saw arbor. The motor has a full load speed of 3,450 r.p.m. and may be furnished up to 5 hp. for two or three phase, 60 cycles, 220 or 440 volts. The saw arbor is mounted in two radial ball bearings which run in grease and are encased to prevent dirt from coming in contact with them. The arbor carries two 4-in. diameter saw collars, a nut and a 16-in. saw blade.

The machine is covered with a one piece cast guard over the top and sides with a hinged steel plate on one

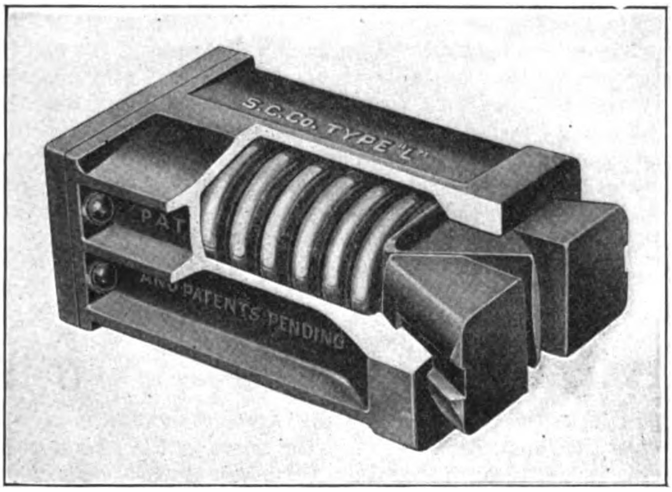


The motor of the Oliver swing saw is mounted on the arbor head

side which can readily be lifted back in order to change the saw blade. The machine is lubricated by means of the Alemite system. When furnished with an 18-in. saw, it will cut planks 12 in. wide and 3½ in. thick. It is approximately 7 ft. 6 in. from center of saw to base of ceiling hanger.

High capacity draft gear

TWO fundamental conditions have vitally affected the efficiency in service of all draft gears. On the one hand there has been the continued trend toward the use of larger and heavier cars, more powerful locomotives and longer trains. On the other hand there is the continued inflexibility of standard overall dimensions within which, for purposes of interchangeability, the draft gear is required to fit and function. Accepting these conditions as the most desirable ground work on which to build, the Sessions-Standard Type L friction draft gear manufactured by the Standard Coupler Company, New York, has been designed for the purpose of combining the following characteristics: High capacity, increasing progressively and uniformly with the gear travel; ample recoil; sturdiness and oversolid strength; 2½-in. travel, all friction; substantial initial compression, both spring and friction; only five parts; electric steel housing.



The Sessions-Standard draft gear designed to give a substantial initial compression and high absorption of energy

Using a tup of 9,000 lb. falling 2 ft. ½ in., an average capacity of 18,375 ft. lb. is obtained. The average absorption of energy is approximately 75 per cent. Thus, the recoil is ample to insure a positive and prompt restoration of the friction elements to the working position and, correspondingly, to insure against sticking.

The 2½-in. of travel is all friction and the gear capacity is progressively uniform up to the closing point. Hence, the frequently encountered situation of an ostensibly high performance in gear capacity, actually accomplished in the last fraction of an inch of travel, is avoided and, as a consequence, sill and other structual stresses are kept well below the danger limits instead of being compelled to suffer the bad effects of an inefficient shock absorbing mechanism.

The provision of initial spring compression definitely retards to the maximum degree the accumulation of slack and enables the user to secure full friction travel and a long continuation of high capacity rating.

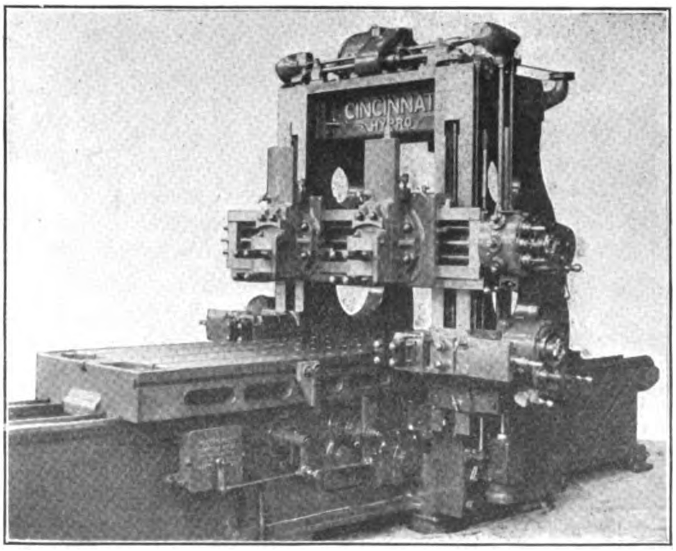
Planer designed for production work

CONVENIENCE for the operator and simplicity of design, elimination of delicate wearing parts, and fool-proof arrangement to eliminate liability of breakages is claimed for the construction of the dial feeding mechanism, rail lift and rapid power traverse to the heads of a planer recently placed on the market by the Cincinnati Planer Company, Cincinnati, Ohio.

All the heads are furnished with selective dial feeds which are graduated to 1/64 in. and arranged so that any feed up to one inch can be instantly set from the operator's position and read from the front of the machine. The rail and side head each have a separate feed with a safety feature so that they can be fed into each other without causing any breakage.

A single turn rail clamping device is used, operating through a crank handle at the end of the cross rail—one turn of this crank clamps the rail securely to the inside face of the housing. The rail clamping mechanism automatically engages the elevating gear when the rail is released and again breaks this connection when it is clamped, making it impossible to engage the elevating mechanism while the rail is clamped. Automatic stops limit the maximum travel of the rail.

The rapid power traverse is so arranged that by one movement either one or both rail heads may be moved across the rail and the tool moves up or down at the same time. Any one of these movements can also be secured independently and instantly, the whole being operated and reversed through one lever. Both side heads are provided with rapid traverse independent of the rail heads. A



Operating levers and points of lubrication conveniently located on Cincinnati planer

slip clutch is used so that no damage results if any one of the heads are run together or beyond their limit. All the control levers are centrally located.

The housings are designed not only with wide faces but so that the heavy thrust of the side head tools is taken by a square section through metal to metal contact. To further increase rigidity at maximum height, the housings are tied together at the top by a full depth box arch, giving balance to the entire machine.

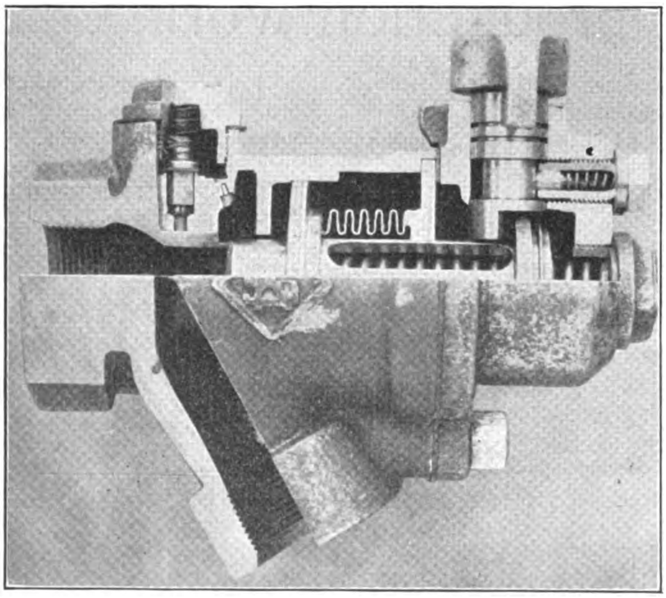
All the slides have the dove tail inverted, resulting in a much heavier cross section through the center. This type of design causes the dove tail bearings to become tighter under pressure. Taper gibs are used throughout on sliding surfaces. Herringbone gears are used throughout the machine.

Continuous lubrication of all moving parts has been given special attention. A pump located in the bed takes oil from the tank through a strainer, then passes it through a filter. Oil is forced into the vees near the center of the bed and distributed through channels the full length of the table so that the table constantly rides on a film of oil. An abundance of oil is always present on short and long strokes. The overflow forms a head or volume in the vees in the front of the table, flushing out any small particles of dirt into the strainer at the end of the bed, thus washing them clean at each stroke of the planer. All the gears in the bed revolve with their shafts which in turn revolve in ground bearings. Filtered oil is flowing constantly to the large chambers surrounding the main bearings, keeping them filled. Before this oil reaches the running bearing it is again filtered by passing through felt wicks. A steady stream of filtered oil is sprayed over all of the running gears. This method keeps the gears above the oil pan and prevents disturbing the sediment which, in time, forms at the bottom of the pan.

The old time oil cup or oilers have been displaced entirely by the use of centralized oil distributors which require filling only once in ten days. One of these distributors has been placed on each side head, on the elevating mechanism, at the end of the rail and one on each of the rail heads. This latter not only lubricates the revolving bearings but also all sliding surfaces. Since this oil reaches the sliding surfaces in the center it tends to keep out any dirt and insures a much longer life to parts that usually receive scant attention, if any oil at all. Proper lubrication is essential to any machine.

Semi-automatic angle cock

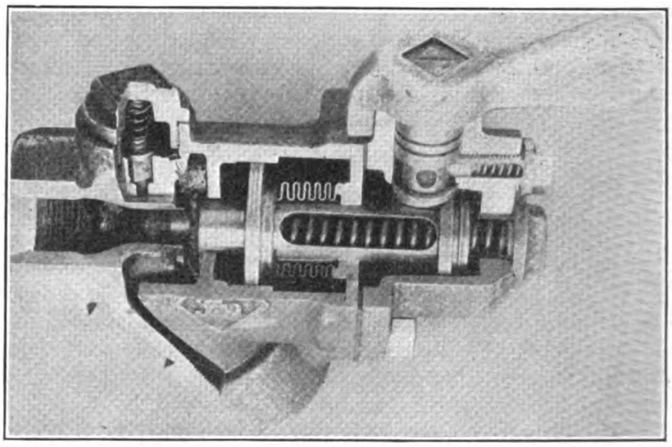
IN order to eliminate the potential danger of serious accidents due to the loss of braking power caused by accidental or malicious closing of angle cocks and yet maintain the present flexibility of the air brake system, a semi-automatic angle cock incorporating new principles has been designed by engineers and associates of the Sprague Safety Control & Signal Corporation, New York. This valve is so constructed that it will automatically maintain an open brake-pipe passage so long as the hose couplings between the cars are connected, irrespective of any accidental or malicious movement of the handle, and will also operate to close this passage automatically when



View showing the angle cock in the closed position

the cars are uncoupled, provided that the operating handle has been placed in the "off" position. It is interchangeable with the present cone valve and is manipulated in precisely the same manner. It may be mixed indiscriminately with older equipment and no changes in procedure will be required in making up train or switching cars.

In the illustration showing the valve in the closed position, it will be seen that the mechanism consists of a cylinder casting threaded at the left hand end for attachment to the brake pipe and at the lower point for attachment of



The angle cock in the open position

the flexible hose coupling. The interior of the casting is divided by an interval baffle plate with a central aperture through which projects an axial extension of the main piston; the face of the axial extension is provided with a rubber valve seat which registers with a bronze valve bushing on the end of the Venturi reduction in the air passage.

When in the "off" position with the hose coupling disconnected, flow of air past this valve seat is prevented by the pressure of the helical seating spring, shown in the sectionalized axial spring guide on the right of the piston. Brazed to the right side of the piston and to the left side of a holding guide plate is a sylphon or flexible metallic bellows. The operation of this bellows is similar to that of a flexible diaphragm except that on account of its form a much longer stroke is permissible.

With the locomotive coupled to a train and all the hose

connections made, the valve handles are turned to the position parallel to the line of the brake pipe in which they are automatically maintained by means of a ball lock. During this movement of the angle cock handle, the valve and operating piston are lifted by the opening cam against the thrust of the seating spring, and as a consequence, brake pipe air flows through the system. The handles of the rear and of the pilot angle cocks of the brake pipe are as at present left in the closed position.

Once the spring-pressed valve is lifted from its seat by means of the opening cam, brake pipe air will flow through the hose connections. This pressure will act on the face of the piston and force the valve to the extreme open position. This pressure will also gradually equalize by the piston and fill the annular space on the outside of the sylphon bellows, but the entire interior of the sylphon is maintained at atmospheric pressure. As a result an unbalanced force of sufficient moment is created by the differential air pressures to overcome the thrust of the seating spring. The piston valve will thus remain in the open or right-hand position so long as the hose couplings are made and any appreciable air remains in the system. If the angle cock handle should be moved to the "off" position accidentally or maliciously, it can not affect the piston valve as the cam is single acting toward the "on" position. Full service and emergency brake applications may be made at will through any number of angle cocks with the handle in the "off" or "closed" position.

When uncoupling cars all that is necessary is to place the handles of both angle cocks in "closed" or "off" position and part the hose. Pressure in the hose will reduce practically instantaneously to atmosphere; the slight amount of air coming through the Venturi reduction strikes the baffle plate and, owing to its peculiar form, reduces the pressure between the baffle plate and the piston to or below atmospheric by means of an ejector action. The pressure momentary trapped in the annular space to the right of the piston and the exterior of the sylphon acts as a powerful momentarily supplement to the spring, and forces the valve to its seat. The action just described is so rapid that the brake pipe air loss is hardly perceptible on a pressure gage. Once the valve has been seated, after parting of the hose, it is maintained in the closed position by the helical spring.

This semi-automatic angle cock will operate without adjustment over all ranges of brake pipe pressure from 70 lb. to 110 lb. and consequently, it is equally suitable for freight or for passenger service.

Vertical and horizontal reaming machine

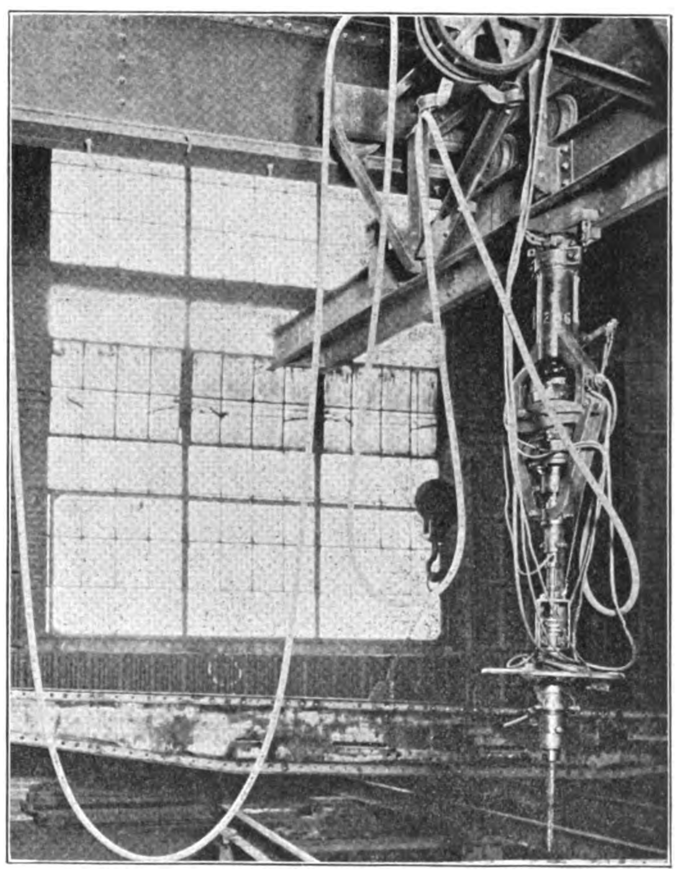
THE American Car & Foundry Company, New York, has recently placed on the market a vertical and horizontal reaming machine developed and used as standard equipment at all the plants of this company.

The machine is controlled by a single operator, who becomes skilled in its use in 10 hours or less, and can then accurately ream holes as fast as he can find them. Mounted on a traveler which can be racked forward or backward by means of an electric motor controlled by a switch located on the hand-wheel, the longitudinal spacing of holes is limited only by the length of the traveler runway. The trolley which carries the machine has been built with ball-bearings, so that a very light push on the hand-wheel will give horizontal control along the traveler bridge; here again the width of the work islimited only by the length of the traveler bridge.

The electric motor used for rotating the reamer bit has a break-test capacity of 6.9 hp., and will ream holes up to 1⅝ in. in diameter. Rotation of the armature is controlled by a contactor, which is operated automatically when the air cylinder, used for vertical control, is lowered or raised. The air valve used for controlling the air cylinder is operated by means of a clamp handle, located on the hand-wheel. A safety clutch is placed between the reamer bit and rotating armature shaft extension. This clutch is released as soon as the operator's hands are removed from the hand-wheel; and, when released, the reamer bit immediately stops rotating. Since the bit, and its extension if used, are the only exposed rotating parts, this clutch insures safety.

The machine has sufficient weight and rigidity to insure vertical reaming, and yet has a certain amount of flexibility, permitting the bit to enter holes not in the proper alinement.

Maintenance consists principally in the occasional renewal of motor brushes and lubrication. All parts are interchangeable, so that any part can be readily duplicated and all parts are readily accessible to inspection and repair. Breakage of reamer bits is practically eliminated, because the weight of the machine has been accurately determined as sufficient to drive the reamer through the hole without applying additional external force, and because of accurate central withdrawal from the hole by means of the air cylinder. Reamer bits can be changed as conveniently as a drill in any standard machine.

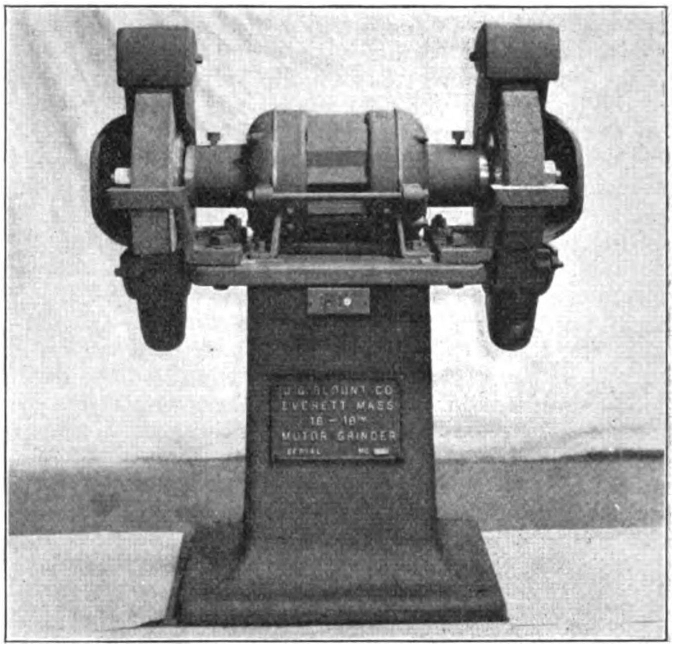


The weight of this machine feeds the reamer in holes up to 1⅝ in. without any exertion on the part of the operator

Ball bearing motor grinder

A 5-HP. ball bearing motor grinder designed for general heavy grinding work has recently been placed on the market by the J. G. Blount Company, Everett, Mass. It is fully equipped with large ball bearings of the deep groove type. The spindle is of carbon steel, turned, ground and threaded, thus insuring a perfect fit in the bearings.

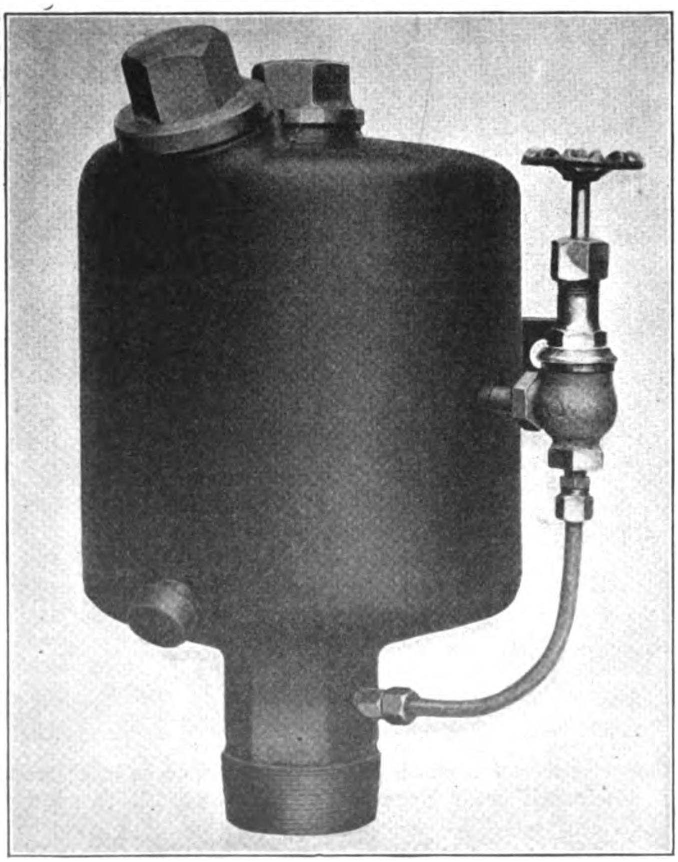
The machine is driven by a Westinghouse 5-hp., 40 deg. rated motor operated at 1,200 r.p.m. It is controlled by a start and stop push button conveniently located on the under side of the pan directly in front of the grinder which is used in conjunction with an automatic starter. The motor end shields are of cast iron, turned with a recess and bolted directly to the motor frame. These shields are also secured in position by two longitudinal bolts at the rear and in front of the motor. The end shield flanges are turned and threaded into the ends of the motor end shields. The wheel flanges on the machine are recessed on the inside. The wheel guards are of the improved safety exhaust type which have a nose-piece and removable covers which increase the sides of the wheel flange and nut for safety protection. Rest supports are adjustable to various positions. The grinder and wheels weigh approximately 1,163 lb. It requires a minimum of floor space.



Double end grinder for general heavy grinding

A decarbonizer for locomotives

THE purpose of the Ehrhart decarbonizer manufactured by the Pilot Packing Company, Chicago, is to introduce a driving journal compound into the valve chest, to prevent an accumulation of carbon in the exhaust passages and eliminate existing carbon deposits.



A cylinder grease lubricator which has no moving parts

It is simple in construction as there are no moving parts or wearing surfaces. No changes or adjustments are needed as the size of the hole in the choke is standard. It is mounted directly on the main valve chest. The tapped holes now used by relief valves may be used if available or it may be connected to the stud at the oil pipe connection, by making the stud sufficiently heavy to support it, and bracing it from the smoke box. All connections should be steam-tight.

When in operation steam enters the body of the decarbonizer from the bottom through the small opening in the choke plugs, percolates through the grease which mixes with the steam and, with each movement of the main valve, a measured quantity of grease is drawn into the valve chamber, the quantity being controlled by the standard size opening in the choke plug. This, in connection with the hydrostatic lubricator, insures thorough lubrication of all surfaces within the valve chest and cylinder, under all conditions.

There are no valves between the decarbonizer and the steam chest. It is filled with new or reclaimed driving journal compound, the filling plug tightly secured and it is ready for operation. It requires no attention from the engine crew other than to know that it is filled regularly, as it works automatically and positively.

To fill the decarbonizer, the drain valve on the side of the decarbonizer is opened to remove any possible accumulation of steam, and then it is filled with grease and the drain valve closed.

The decarbonizer shown is the No. 2 medium size, holds 3 lb. of grease and will run 300 miles without refilling. Size No. 3 holds 1½ lb. of grease and will run from terminal to terminal without refilling.

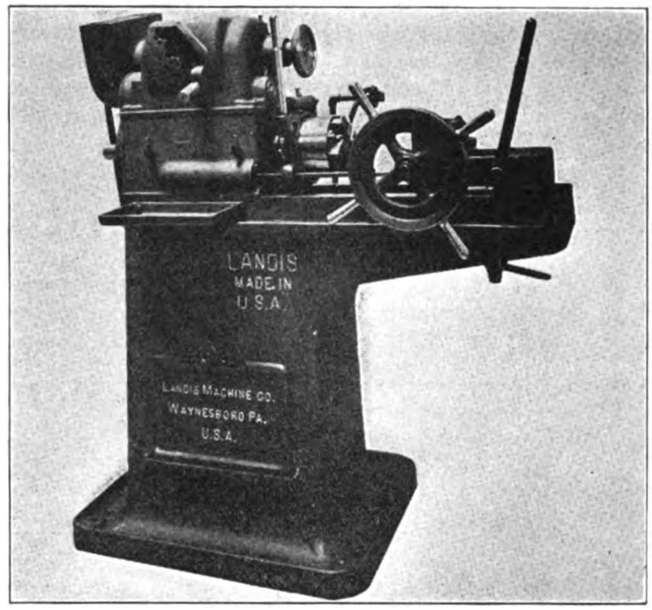
One-half inch single head threading machine

A NEW design of ½-in. single head threading machine has recently been placed on the market by the Landis Machine Company, Waynesboro, Pa. This machine has a geared headstock and a single pulley drive. The machine has four speeds, which give to the die head the following r.p.m.: 157, 226, 315 and 441.

The die head is opened and closed automatically by the carriage, or by hand at predetermined limits. The vise has a horizontal side-wise as well as a vertical centering adjustment. This feature insures a perfect and permanent alinement with the die.

A full supply of cooling lubricant is maintained at the die head by a rotary pump and there is a special control valve at the die head for shutting off the oil supply when necessary. The frame is cast in one piece with a fluid tight bottom. The driving pulley is mounted on top of the machine.

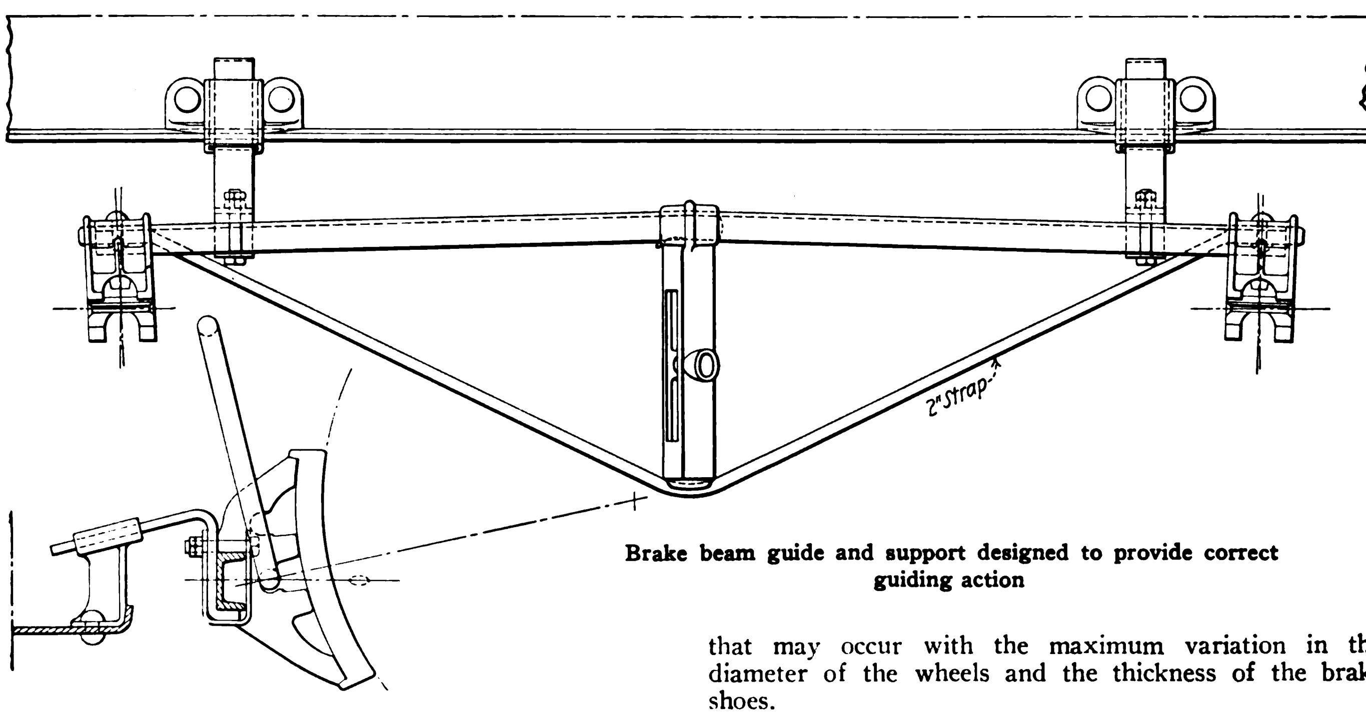
This machine is readily converted to motor drive. The power is transmitted from the motor shaft to the drive shaft of the machine by means of a belt. The motor is mounted on a plate placed on top of the headstock, so as to economize floor space, and to prevent dirt and oil from accumulating on the motor parts. The floor space occupied is 4 ft. 1½ in. by 1 ft. 11½ in. The net weight is 950 lb.



The die head is opened and closed automatically by the carriage, or by hand at predetermined limits

Huntoon brake beam guide and safety hanger

A BRAKE beam guide and support combining the advantages of simplicity, strength and superior guiding action has been introduced by The Bradford Corporation, New York. As shown in the drawing, this device consists of a guide casting riveted to the spring plank and an arm passing through the casting and bolted to the compression member of the brake beam with a bent clamp. Two of the guides are applied on each brake beam at any convenient location near the ends of the beams. The guide arm is smaller than the slot in the casting and normally is in contact only on its upper surface. The angle of the arm and the slot is such that the brake shoe is held in proper alinement to insure even wear. Correct guiding action is afforded over the entire range of travel that may occur with the maximum variation in the diameter of the wheels and the thickness of the brake shoes.



Brake beam guide and support designed to provide correct guiding action

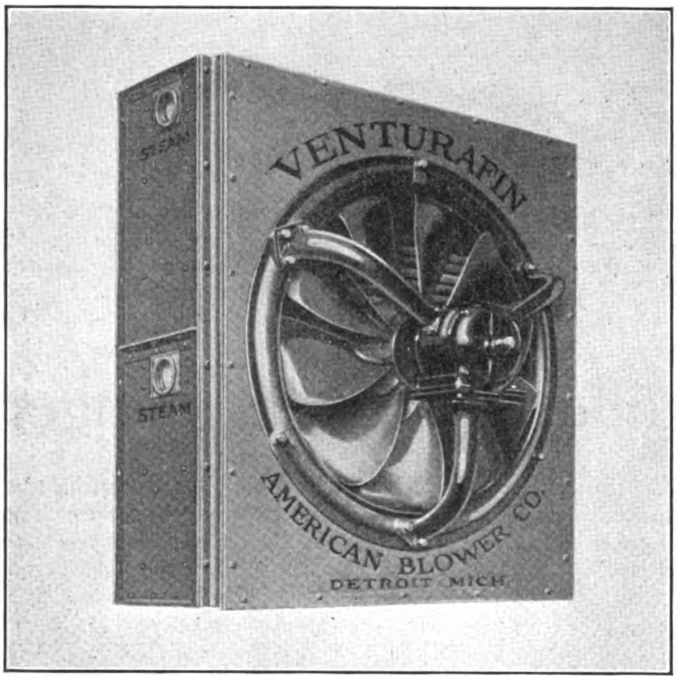
Because of the location and the construction of this guide, there is very little interference in case it is necessary to remove or replace brake beams. When the clamp bolt is removed the guide arm can be slipped through the

guide casting far enough to permit the brake beam to pass the projecting end.

One of the special features of this guide and support is the fact that it functions the same whether the frictional force applied to the brake shoe is upward or downward, and, therefore, will prevent brake beams from climbing the wheel as well as keep them from dropping. The point at which the guiding effect is exerted is a considerable distance from the hanger hole in the brake shoe and because of this condition, slight variations in the relative location of the members or the lengths of the hangers will not have any appreciable effect on the alinement of the brake shoe with respect to the wheel. The guide arm and guide casting are amply strong to withstand forces to which they are subjected in case the hanger fails to support the beam.

Heating unit of large capacity

CONSIDERABLE difficulty is often experienced in heating satisfactorily certain railway shops, or certain parts of the shop. The American Blower Company, Detroit, Mich., has recently placed on the market a self contained heating unit which is adaptable for use in such locations.



View showing general design and construction of a self contained indirect heating unit

The heating unit is light and compact. The steam tubes over which the air circulates are made of straight seamless copper and around each tube is wound a helical brass fin which increases the heat radiating surface. This fin is wound around the tubes in such a manner that much of its surface is in contact with the outer surface of the tube and this joint is later treated so that the fin and the tube become metallically integral, to facilitate the transmission of the heat from the tube to the fin.

In building these tubes into heating units, the method of assembly is simple and strong. The tubes are arranged in rows and the ends are pressed into a thin flexible copper plate, the holes in which are slightly smaller than the tubes. This gives tight flange connections which are later soldered. The flexibility of the plate takes care of expansion and contraction. Semi-cylindrical headers provided with steam connections are then placed over the ends of the tubes and locked on by means of a folded seam construction. Each unit includes a standard motor-driven fan.

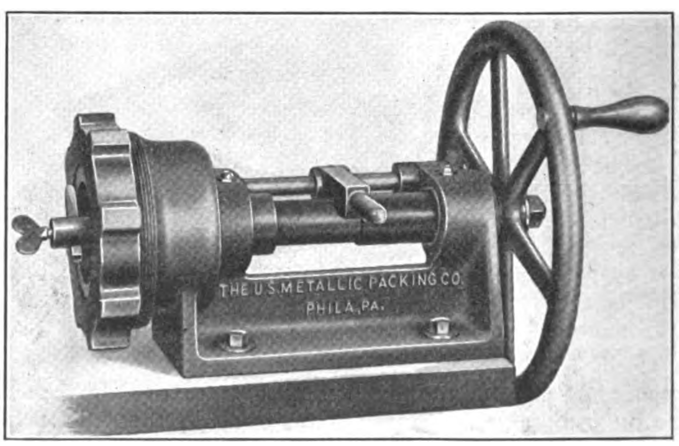
The heating unit shown in the illustration delivers approximately 650,000 B.t.u. an hour, with initial or room and final temperatures of 40 deg. and 111.3 deg., respectively. At initial and final temperatures of 70 and 128 deg., its capacity is approximately 500,000 B.t.u. an hour. The fan operates at 565 r.p.m., delivering 8,000 cu. ft. of air per min. These units can be combined in one assembly containing as many units as desired, depending on the size of the room to be heated.

Hand boring lathe for King packing

THE practice of sending packing rings from the enginehouse to the back shop for reboring is an inefficient and costly one. To facilitate this work the United States Metallic Packing Company, Philadelphia, Pa., has recently placed on the market a hand-operated lathe for boring out King metallic packing.

The lathe is composed of a body with the chuck cast integral. The chuck is machined to accommodate a 5-in. King packing ring and is adjusted to the various sizes of rings by means of reducing bushings. The boring bar is made in one piece with a 3/8-in. square high speed tool bit fitted in one end and which is held in place with a wing set screw. The opposite end of the boring bar is fitted with a large wheel which is rotated by hand by means of a handle that is free to turn on a small spindle. The boring bar revolves in bronze bushings forced in holes which are bored concentric with the chuck. This insures absolute concentricity of the ring.

In the center of the boring bar a reduced threaded portion is engaged by a half nut that gives the boring bar a longitudinal motion when the wheel is revolved. The half nut can be raised to allow the boring bar to be moved by hand for quick return to the original position.



Convenient machine for quickly machining King metallic packing

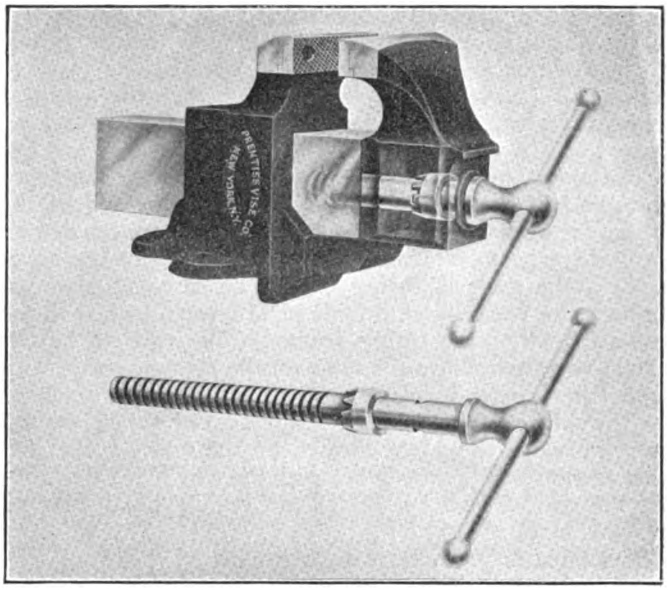
The packing ring is clamped in the chuck by means of a nut that has an internal thread which engages an external thread on the chuck. The nut is drawn up tightly by hand, which is sufficient to clamp the rings. The body of the lathe is drilled to accommodate four bolts or lag screws for fastening it to the end of a bench.

Improved vise screw collar

THE accompanying illustration shows a new collar fastening for vise screws which is a recent improvement made to the vises manufactured by the Prentiss Vise Cmpany, New York. The purpose of this collar is to fasten the screw to the front jaw and draw out this jaw when the screw to the front jaw is turned to open the vise. If the collar or any other device used for fastening the main screw to the front jaw becomes loose, there is lost motion which has to be taken up before the vise is opened or closed. The new collar does not depend on a set screw to hold it in its proper position.

When the screw heads are forged on the main screws, two depressions are also forged on opposite sides of the screw shank. A castellated collar having prongs of varying lengths with prongs of the same length opposite each other are slipped over the screw. Two of these prongs are driven into the depressions in the screw shank making the collar for all practical purposes an integral part of the screw. This arrangement makes it certain that the front jaw will always follow the screw without any noticeable play or lost motion.

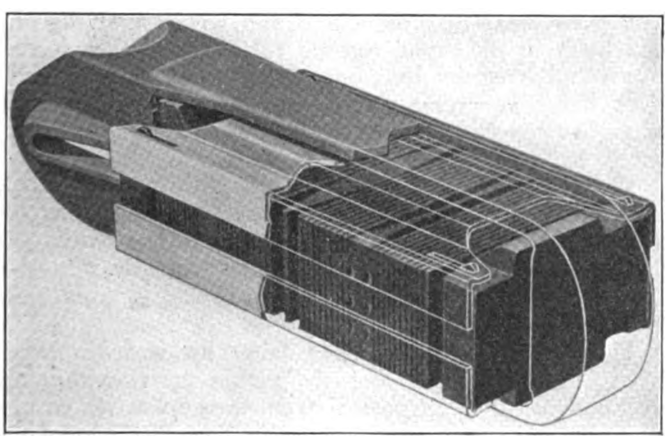
To minimize wear on these parts, all the bearing surfaces are machined. The collar itself is drilled to size to insure a close fit on the screw. Should any wear develop at these points through lack of lubrication and long use, a blow with a hammer on a flat punch placed against the prongs, will cause them to stretch and take up the wear. If this adjustment should not be sufficient, the depressed prongs can be cut off with a chisel and the collar turned around and a longer set of prongs driven in the depressions, thus holding it in a permanent position.



Prentiss vise screw collar designed to prevent lost motion

Improved draft gears for freight cars

THE illustration shows an enclosed type of draft gear made for capacities of 200,000 to 1,000,000 lb. and in standard sizes to fit 18½ in. and 24⅝ in. pockets, and in special sizes to suit special conditions.



Phantom view, showing the construction of the Waugh enclosed draft gear

There are over 4,000 sq. in. of frictional surfaces in addition to the spring capacity on a Standard 29⅛-in. draft gear. Its capacity is controlled by increasing or decreasing the number of plates in each group. This flexibility of design enables a railroad, if desired, to transfer the gear from one car to another and arrange the groups of plates to meet the capacity of the car.

In construction, the draft gear consists of straight spring plates, end followers with convex curved faces, spring end separators with concave curved faces and a convex center separator. The spring plates are oil tempered and the followers and separators are drop forgings and malleable castings.

In operation the groups of spring plates are deflected over the curved faces of the followers and separators which limit the deflection and protect the plates against injury from over solid blows.

The deflection of these plates from their normal straight form is attended by an increasing frictional adhesion of the surfaces, which adds to their cushion capacity and retards the recoil upon the return of the gear to normal position. When fully compressed, the plates in each group take a bearing over their entire area.

As the standard height of the spring plates and operating parts is 6 in., a bottom guide casting and a top guide pressing are used to retain the gear in approximately the vertical center of the standard 9¼ in. pocket and yoke. These guides also retain the gear in alinement regardless of variation in sill spacing. This draft gear is manufactured by the Waugh Equipment Company, Chicago.

High speed metal cut-off saw

THE machine illustrated below was designed by the Hunter Saw & Machine Company, Pittsburgh, Pa., to cut cold metal by means of a high rotative speed circular saw, particularly adapted for tubing and metal sections. The motor and saw blade are mounted on opposite ends of a tilting frame, the machine is driven by a belt from the motor and an idler pulley is located in the frame to give a maximum belt contact on the arbor pulley with a minimum tension. The saw arbor and idler pulley are equipped with S. K. F. self-alining ball bearings in oil-tight dust-proof housings. The belt and saw blades are fully protected by steel guards to conform with safety specifications. A pan is attached to the under side of the table enclosing the saw at its lowest point to catch cuttings. This pan can be dropped and the cuttings removed, which operation requires only a minimum of time.

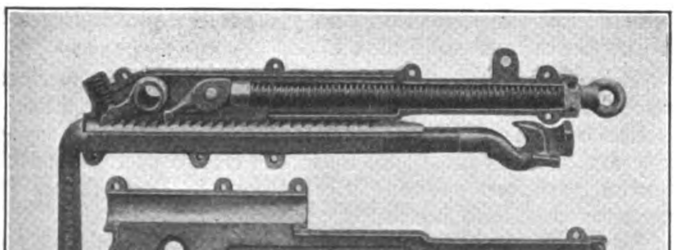
The motor support is provided with adjusting screws to give the belt the desired tension. The motor end of the tilting frame has a cushioned stop and is connected with a spiral spring to return the frame to the height necessary to clear the material being cut. The saw is fed down through the work by an offside hand lever attached to the forward end of the tilting frame. The work to be cut should be raised above the table on the clamping side with supporting strips furnished to prevent it from pinching the saw blade when passing through. For rapid production, the work should be located on the table so that the least section will be in contact with the saw blade throughout the cut. These conditions are readily obtained with this machine.

The table is provided with a graduated quadrant stop that can be set to any angle within the sweep of the saw blade used. This stop is held firmly in position on the table by a bolt moving through T-slots. The material is clamped by a quick-acting eccentric jaw. The machine has a capacity for tubes up to 4 in. in diameter. It is equipped to take care of a saw of 24-in. maximum overall section. It is driven by a 7½-hp. motor with a speed of 1,750 r.p.m. The machine occupies a floor space of 31 in. by 24 in. and can be readily moved if desired.

Hunter saw for cutting metal cold

Automatic slack adjuster for freight cars

WHILE the air brake today is one of the most highly developed and efficient devices used on freight cars, every part from the brake shoes to the brake cylinders must be in accurate adjustment for smooth and efficient braking of the long trains in use today. Varying slack on the different cars in the train caused by wear of brake shoes and wheels and the pins and holes in the brake rigging result in different piston travel and irregular braking action throughout the train. This irregular braking action is the principal cause of break-in-twos and damage to cars and lading caused by rough handling.

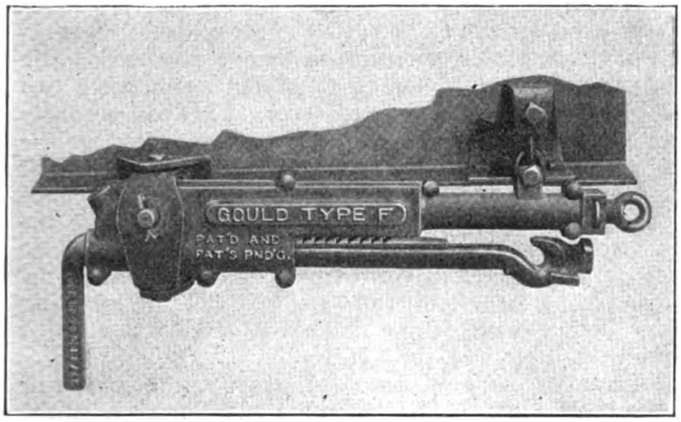


The contained parts of the Gould automatic brake slack adjuster

The Gould Coupler Company, New York, has spent a number of years in the development of a simple and efficient device for freight equipment and The Symington Company, Rochester, N. Y., now presents the result of this study and development in the Type F freight slack adjuster.

This adjuster automatically takes up wear in shoes, wheels, pins, etc., keeping the piston travel within approximately ½ in. of normal from the application of new shoes until they are worn out. When replacement of one or more shoes is necessary, the adjuster may be manually set back for this purpose, and upon the next application of the air, the device is automatically brought into proper adjustment. It is not necessary for the maintenance gang to make any calculations to determine the correct setting of the device as it is not possible to set it improperly.

This adjuster takes the place of the usual dead lever stop. It is attached to the bottom flange of one center sill by two forged brackets designed to allow the necessary flexibility so that the adjuster will accommodate itself to



A slack adjuster for freight cars which takes the place of usual dead lever stop

all normal movement of the dead lever on straight and curved track.

The adjuster consists of a malleable iron housing which serves as a guide for a cylindrical holding rod, the latter being flexibly connected to the dead lever. This holding rod is itself held in position by a sliding rack strip which in turn is held by a pawl or dog. Mounted in the casing above the holding rod is an adjusting rod having a dog or pawl also engaging the holding rod rack strip and held in its normal position by the spring which encircles the adjusting rod. Attached to the eye at the rear of the adjusting rod is a connection which passes under the body bolster and is slidably attached to the top connection or pull rod of the brake rigging just beyond the live lever. An adjustable stop clamped to the top connection or pull rod actuates the adjusting rod as soon as any wear has developed or as soon as the cylinder push rod moves more than the predetermined amount. Assuming wear to have taken place, an application of the brakes moves the adjusting rod so that the movable pawl picks up one tooth on the holding rod rack strip. On the release of the brakes the spring returns the adjusting rod to its normal position carrying the holding rod with it and the holding rod is maintained in its new position by its engaging pawl. This operation is repeated as soon as additional wear amounts to the equivalent of one tooth space on the ratchet. In effect, the device is a dead lever stop with a large number of adjusting holes which automatically changes the position of the dead lever pin until the shoes are worn out.

Portable sanding machine for car repair work

The usual method of finishing metal parts used on passenger cars is by hand filing and buffing. The Carborundum Company, Niagara Falls, N. Y., have placed on the market a portable sanding machine which takes the place of the hand method of finishing. This machine grinds away the metal with a special flexible abrasive disc driven by a motor through a flexible shaft. The disc is coated with Aloxite grains, a hard, sharp and tough abrasive or grinding material manufactured by the Carborundum Company.

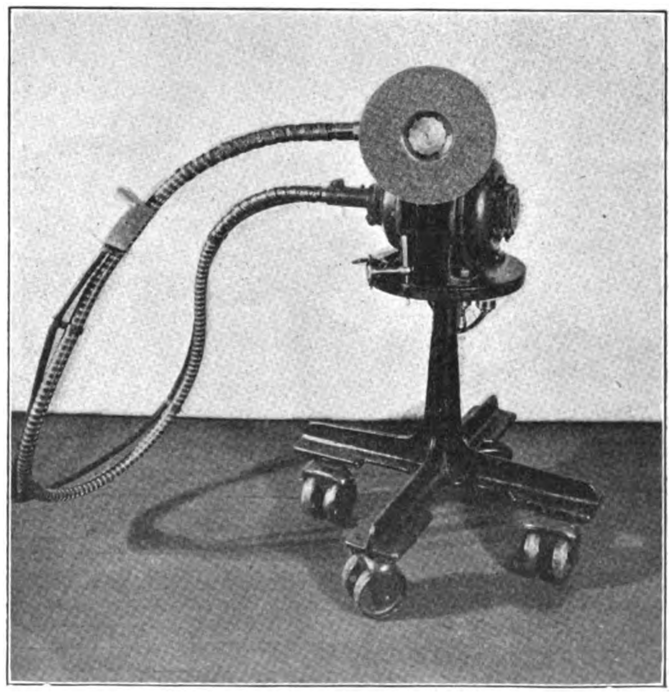
The motor is mounted on a rigid cast iron pedestal, 24 in. high supporting a swivel table providing for a swing of the motor half-way around, or an arc of 180 deg. This feature adds greatly to the adaptability of the unit to any required position during the continuous grinding operations. The pedestal is supported by four substantial double castors, permitting ease of movement and travel, without danger of upsetting. A holder mounted on the table provides a secure resting place for the machine head when not in use.

Each machine is equipped with a one-horsepower motor built to such specifications as may be required to meet the power conditions of the user. The flexible shaft which drives the grinder head is of the most modern and approved type, especially adapted to meet heavy duty conditions. The main castings of the grinding head are of aluminum to insure lightness plus requisite strength and durability.

The assembly shafts and spindles are of steel, supported in ball bearings, reducing friction to a minimum. Heat treated, specially tempered steel mitre gears running in an oil-tight chamber packed with grease provide the angular drive from the flexible shaft. Ample facilities are arranged for the proper lubrication of all moving parts.

The grinding head is designed to be perfectly balanced and the driving mechanism is so planned and constructed as to eliminate vibration. The head is provided with two handles which are located to insure accurate control and convenience in operation.

The Aloxite grains with which the discs are coated



Flexibility of control and operation are features of the carborundum portable sanding machine

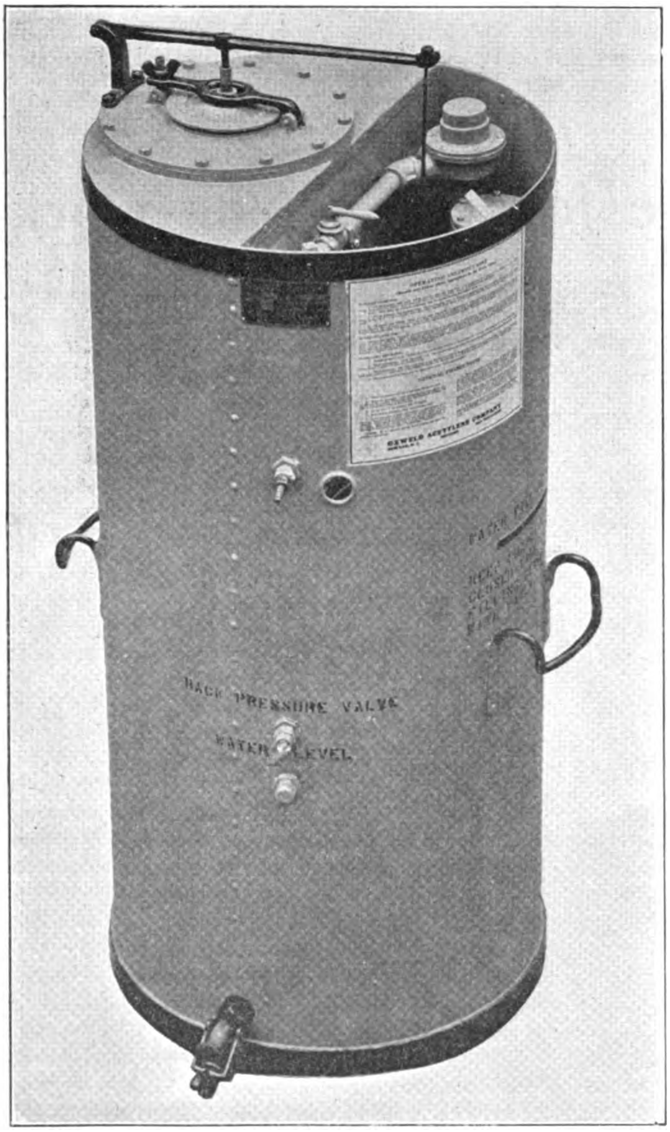
are uniformly graded and are coated on the discs in such a way as to allow for a free cutting action. There is a definite clearance between the grains so that every grain

has full cutting capacity. The grains are coated on a strong, durable backing of cloth drills. This cloth-backed disc is then securely fixed to a special fibre board disc with a moulded, counter-sunk center provided with six pin holes which locate over the pins in the special lock nut that holds the disc securely to the head. These discs are furnished in a standard size of 9¼ in. in diameter.

Flexibility is another important feature in connection with the discs and the grinding head. Evenly supporting the disc is a flexible and compressible pad which yields to the slightest pressure, thus conforming to work projections. This feature together with the flexibility of the discs itself permits the disc to conform readily to mouldings, beadings, sharp curves and contours, even under light pressure.

Portable acetylene generator

A SMALL generator for producing acetylene at low pressure for welding and cutting has recently been developed by the Oxweld Acetylene Company, New York City. The generator, which takes 35 lb. of carbide at one charge, can be transported readily from place to place, thus providing a portable supply of generated acetylene gas. When empty, the generator weighs only 210 lb.



Oxweld portable, low pressure, acetylene generator

A new principle of feed control is used which might be called a "heavier-than-water" float. A vertical partition, extending nearly to the bottom into a water seal, divides the generator shell. One side is gas tight and contains the carbide hopper at the top. The upper part of the other side contains gas regulating and protective devices, and an automatic carbide feed control. Generation of the first acetylene causes water to rise on this side of the partition high enough to all but submerge a pan full of water, hung to a control lever. This pan normally acts as a weight acting counter to a spring, but as the water rises about it, its apparent weight is diminished and the carbide hopper valve is closed by the action of the spring. As acetylene is drawn off, water rises in the gas compartment and correspondingly lowers under the float. This relieves some of the buoyancy under the water pan, which, gathering weight with the receding water, depresses the spring and allows a small amount of carbide to drop into the generator.

Because of its low center of gravity, the generator rights itself when tilted at an angle of 30 deg. It works perfectly at an inclination of upwards of 10 deg. No adverse effects result if a generator, while in operation, is knocked over. Nearly all fittings are enclosed in the cylindrical shell and there is little, if anything, projecting which may be injured by a fall on a concrete pavement.

Ohio universal and tool grinder

A NO. 2-L universal and tool grinder intended primarily for use in railroad and automobile shops for grinding reamers, boring bars, taps and similar tools, has been developed by the Oesterlein Machine Company, Cincinnati, Ohio. The machine will take work up to 30 in. between centers and has a 9-in. swing with a 7½-in. vertical movement. It is of the milling machine type of construction.

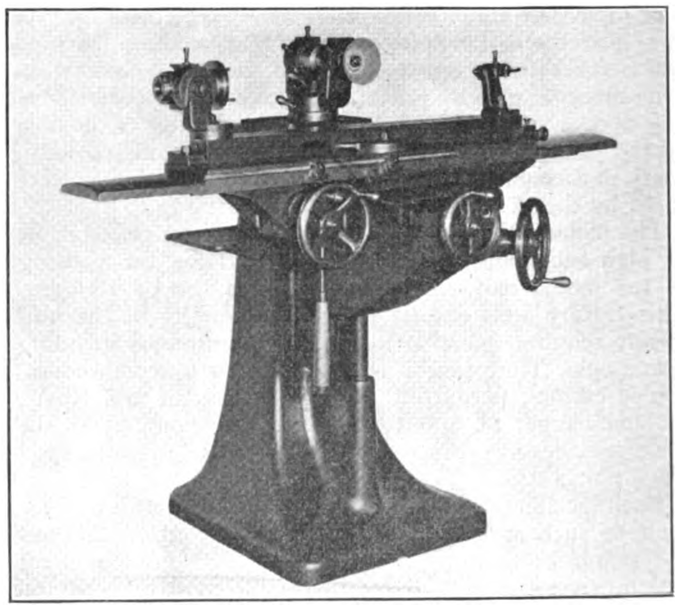


Table of the Oesterlein tool grinder may be reciprocated by means of a ball-bearing lever feed

The table reciprocation may be obtained through a handwheel, in which case two gear ratios are available. In addition, a ball-bearing lever feed is provided that may be engaged at any point to permit the operator to use either his right or left hand for reciprocating the table. This lever feed has also been added to the Nos. 2 and 3 grinders built by this company.

General News

As a part of its expense-reduction program, the Pennsylvania has ordered the abandonment of the heavy repair shop on the Marion division at Logansport, Ind. A large number of the 800 men affected by this order have been offered work at either Columbus, Ohio, or Fort Wayne, Ind., where the heavy repair work will be done in the future.

Ninety employees of the Pennsylvania System were retired from active duty on August 1, under the company's pension plan, and placed upon the "Roll of Honor." Seven of those have been in the employ of the road for 50 years or more each, while 55 have had records of 40 years' service or more. Since the establishment of the Pennsylvania's pension plan, on January 1, 1900, a total of 18,374 employees have been retired under its provisions; of whom 8,262 are still living.

Court news

Federal Jurisdiction Exclusive as to Safety of Locomotives.—The federal district court for northern Georgia holds that since Congress has provided for making regulations for the safety of locomotives, this field is exclusively occupied by federal legislation. The carriers have proposed and the commission has not required a rule of inspection providing for automatic firebox doors. Therefore, Georgia Laws of 1924, p. 173, requiring locomotives to be equipped with such doors is held invalid as to locomotives engaged in interstate commerce.—Atlantic Coast Line v. Napier, 2 F. (2nd) 891.

New Santa Fe cars make successful trial trip

The Atchison, Topeka & Santa Fe has just purchased from the Pullman Company and placed in service a dining car and a club lounge car which embody a number of revolutionary changes in design. These cars, which are intended to be operated as a unit, have made a trial trip from Chicago to Los Angeles and return in the California Limited. They depart from conventional design primarily in their interior arrangement which has been planned with a particular view to increasing the efficiency of dining car service. These cars are still considered in the experimental stage and their operation is being watched closely. Patents have been granted to Byron S. Harvey, of the Harvey System, on a number of features of the diner.

Train control installations

The Interstate Commerce Commission has postponed from July 1 to February 1, 1926, the date for fulfilment by the Pere Marquette of the commission's order requiring an installation of automatic train control.

By an order dated July 21 the Illinois Central has been authorized to install automatic train control on its road between Waterloo, Iowa, and Fort Dodge, 100 miles, instead of installing on a division between Chicago and Memphis as was called for by the commission's order of January 14, 1924. This action was taken by the commission on condition that the order shall not result in extending the time within which the order shall be complied with, namely February 1, 1926. The road also must agree that the amendment does not entitle it to claim, in court or elsewhere, any extension of time beyond February 1, 1926.

Cost of locomotive fuel

The cost of fuel coal to the railroads showed a further reduction in April as compared with last year and the earlier months of this year, according to the monthly statement issued by the Interstate Commerce Commission. On the other hand, the cost of fuel oil showed an increase. The average cost of fuel for road locomotives in freight and passenger train service (charged to operating expenses) for Class I steam railways in April was $2.79 a ton, as compared with $3.19 last April and $2.81 for four months of this year. There was also a reduction in the number of tons used, and the total cost for the month was $20,532,551. The average cost of fuel oil was 3.29 cents per gallon, as compared with 2.80 cents last April and 3.11 cents for four months. The total cost of coal and fuel oil for four months this year was $112,885,814, as compared with $132,244,549 for the corresponding period of last year.

American Locomotive Company to build Whaley constant pressure oil engine

The American Locomotive Company has acquired the exclusive license for the use of the Whaley constant pressure oil engine on rails in the western hemisphere. An engine of this type has recently been built by the Sun Shipbuilding & Dry Dock Company, Chester, Pa. It departs in one essential respect from all other present internal combustion engines in that a piston valve driven by the valve motion of the type commonly used in steam engineering practice opens the cylinder clearance into communication with a receiver of large capacity relative to the clearance, the valve opening synchronizing with the period of the fuel injection. Through this feature it is claimed that the combustion pressure does not rise above the compression pressure, and that an indicator card similar to that of a steam engine is produced. The limiting of the maximum pressure is expected to make possible the production of an engine which will weigh less than 100 lb. per horsepower. The engine just completed is a single acting, four-cylinder, two-cycle machine designed to develop 750 hp.

Meetings and Conventions

American Welding Society

The fall meeting of the American Welding Society will be held on October 21, 22 and 23 at the Massachusetts Institute of Technology, Cambridge, Mass. Exhibits of welding and welded products are to be featured at this meeting and actual demonstrations of welding and cutting will start each morning at 9 a. m. and last until 5 p. m. Five technical sessions are scheduled, at which papers on thermit welding, gas welding of power plant piping, industrial applications of arc welding and economies effected through its use, selection of materials for welding, and spot welding of automobile bodies will be presented.

Machine tool exhibition at New Haven, Conn.

The fifth annual machine tool exhibition will be held in New Haven, Conn., September 8 to 11, inclusive, in conjunction with the sessions of the Machine Shop Practice Division of the American Society of Mechanical Engineers. A diversified number of addresses, papers and discussions of great significance to men concerned with machine tool work of any description, are included in the three-day program. The following papers and the time during which they will be presented should be of particular interest to railroad machine shop men.

Centerless grinding, Wednesday afternoon; cylindrical precision lapping and high speed cutting of brass, Thursday afternoon; round table dinner discussion, Thursday evening of four subjects—namely, inspection methods and precision measurements, power press work, production milling and shop training methods, and Friday afternoon, shop training methods.

Over 100 manufacturers will present the latest developments in the machine tool and accessory equipment showing the advancement made in the machine tool industry during the past year. The exhibit will be held at Mason Laboratory, Sheffield Scientific School of Yale University.

General foremen to meet in September

The twentieth annual convention of the International Railway General Foremen's Association will be held at the Hotel Sherman, Chicago, September 8 to 11. Among the interesting topics to be considered are automatic train control; supervision of repairs of special appliances such as boosters, reverse gears, etc.; straight line or spot system of car repairs and routing system to increase locomotive shop output. An additional topic which promises to be of unusual value and provoke a large amount of discussion is entitled "What Can the General Foreman Contribute to Obtain More Ton Miles per Shop Man Hour?"

Program for the Regional meeting of the A. S. M. E. elects officers for 1926

The American Society of Mechanical Engineers will hold a regional meeting on October 5, 6, 7 at Altoona, Pa. As the technical sessions will relate to transportation problems, a more appropriate surrounding for the meeting could not have been selected as the large manufacturing and repair shops of the Pennsylvania System are located at Altoona. Those attending the convention will be favored with the opportunity of visiting the Altoona shops, particularly the new $2,000,000 locomotive repair shop which has been completed within the last two years.

The following program offers to those attending an opportunity of not only seeing the points of interest in the vicinity of Altoona, but of listening to a number of speakers well-known in the railroad world.

Monday, October 5

Morning and afternoon: Meeting of Council of The American Society of Mechanical Engineers.
Afternoon: Miscellaneous entertainment, such as golf and automobile trips to points of interest.
Evening: Dr. William F. Durand, president, A. S. M. E., presiding.
Conferment of Honorary Membership in The American Society of Mechanical Engineers on General William Wallace Atterbury, vice-president of the Pennsylvania Railroad System.

Tuesday, October 6

Morning: Technical Session.
Afternoon: Trip by special train to Old Portage where party will detrain to see the Old Portage where the incline planes were located by which passengers by canal were taken over the mountains. Special train will return by the Horse-Shoe Curve to Altoona.
Evening: Entertainment in Altoona.

Wednesday, October 7

Morning: Technical Session.
Afternoon: Visit to Altoona shops. One of the features will be the operation on the test plant of the first electric locomotive ever tested on it.

Technical Sessions

The entire program for the technical sessions has not been completed, but the following speakers have accepted:
Samuel Rea, president, Pennsylvania Railroad, on American Transportation.
Lawford H. Fry, metallurgical engineer, Standard Steel Work Co., Burnham, Pa., on Influence of the Altoona Test Plant on Steam Locomotive Development.
Samuel P. Bush, president, Buckeye Steel Castings Co., on Engineering Development in the Industries Generally to meet Railroad Wants.
A. J. County, of the Pennsylvania Railroad, on the Growth of a Great Transportation System.

Elaborate arrangements are being made to take care of the ladies and an active committee will be in charge of a series of interesting events for them.

Master Blacksmiths' Supply Men's Association elects officers for 1926

A total of thirteen railway supply companies had exhibits of their products at the twenty-ninth annual convention of the International Railroad Master Blacksmiths' Association, held August 18, 19 and 20, at Cleveland, Ohio. The annual meeting of the Supply Men's Association was held at the Hotel Winton, August 20, at which time the following officers were elected: James A. Murray, Ajax Manufacturing Company, president; A. N. Lucas, The Oxweld Railroad Service Company, vice-president, and Edwin T. Jackman, Firth-Sterling Company, secretary-treasurer. The following is a list of the exhibitors with their representatives:

Ajax Manufacturing Company, Cleveland, Ohio.—Forgings, model of board drop hammer, model of 4-in. Ajax upsetting forging machine, and literature. Represented by J. R. Blakeslee, J. A. Murray, A. L. Guilford, G. Fistoe and W. W. Criley.

Anti-Borax Compound Company, Ft. Wayne, Ind.—Welding compound and literature. Represented by Charles O. Kahre.

Colonial Steel Company, Pittsburgh, Pa.—Crucible for melting steel, specimens of hardened fractures, raw alloy material used in making high-speed steel, specimens of alloy and carbon tool steel fractures, and literature. Represented by F. L. Stevenson.

Crucible Steel Company of America, Pittsburgh, Pa.—Forging machine gripper dies, taps, high-speed steel and Sanderson special tool steel. Represented by F. Baskerfield, A. E. Jones and W. M. Stevenson.

Firth-Sterling Steel Company, McKeesport, Pa.—C. Y. W. bolt and rivet dies, special rivet buster. Represented by Edwin T. Jackman, Willard C. Royce, Thomas A. Larecey, and William A. Nungester.

E. F. Houghton & Co., Philadelphia, Pa.—Railway springs, quenching oils, "draw-temp", hydrocarbonate base black, "quick light A", literature. Represented by Wilbur Wriglet, W. A. Fletcher and J. E. Burns, Jr.

Metal & Thermit Corporation, New York.—Specimens of thermit welding, literature. Represented by Henry D. Kelly and W. H. Moore.

National Machinery Company, Tiffin, Ohio.—Literature. Represented by E. R. Frost, Karl L. Ernst, H. E. Lott and F. J. Mawey.

Oxweld Railroad Service Company, Chicago.—Gas cylinder gages and torches. Represented by William A. Champieux, A. N. Lucas, William Jones, J. W. Boyd and J. W. O'Neil.

Data from Car Service Division Reports.

Pilot Packing Company, Chicago.—Packing, Literature. Represented by W. W. Bacon.

Railway Journal, Chicago.—Copies of publication. Represented by E. C. Cook.

Railway Mechanical Engineer, New York.—Copies of publication. Represented by Marion B. Richardson.

Rockwell, W. S., Company, New York.—High and low pressure burners and blast gates, fuel oil appliances, forging and heat treating furnaces, literature. Represented by C. P. Cogswell, D. M. Powers and R. M. Atwater.

Ulster Iron Works, Dover, N. J.—Special staybolt iron, engine bolt iron, drilled hollow staybolts, hammered iron billets. Represented by C. F. Barton, E. W. Kavanaugh, J. C. Campbell and L. E. Hasman.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs.

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

American Railway Association, Division V.—Mechanical—V. R. Hawthorne, 431 South Dearborn St., Chicago.
Division V.—Equipment Painting Section.—V. R. Hawthorne, Chicago. Next meeting September 15, 16 and 17, 1925, at St. Paul Hotel, St. Paul, Minn.
Division VI.—Purchases and Stores.—W. J. Farrell, 30 Vesey St., New York.

American Railway Tool Foremen's Association.—G. G. Macina, 11402 Calumet Ave., Chicago.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Regional meeting October 5-7, at Altoona, Pa. Technical program on transportation problems. Railroad Division. A. F. Steubing. Bradford Corp., 25 West Forty-third St., New York.

American Society for Steel Treating.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio. Annual convention week of September 14, 1925, Cleveland, Ohio.

American Society for Testing Materials.—C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago, Ill. Annual meeting, October 27 to 30, inclusive, Hotel Sherman, Chicago.

Canadian Railway Club.—C. R. Crook, 129 Charron St., Montreal, Que. Regular meetings second Tuesday in each month, except June, July and August, at Windsor Hotel, Montreal, Que.

Car Foremen's Association of Chicago.—Aaron Kline, 626 N. Pine Ave., Chicago, Ill. Meeting second Monday in month, except June, July and August, Great Northern Hotel, Chicago, Ill.

Car Foremen's Association of St. Louis.—R. E. Giger, 721 North 23rd St., E. St. Louis, Ill. Meetings, first Tuesday in month, except June, July and August, at the American Hotel Annex, St. Louis.

Car Foremen's Club of Los Angeles.—J. W. Krause, 514 East Eighth St., Los Angeles, Cal. Meeting second Friday of each month in the Pacific Electric Club building, Los Angeles, Cal.

Central Railway Club.—H. D. Vought, 26 Cortlandt St., New York, N. Y. Regular meetings, second Thursday each month, Hotel Statler, Buffalo, N. Y. Next meeting September 10. A paper on The Lima 2-8-4 Locomotive will be presented by H. W. Snyder, mechanical engineer, Lima Locomotive Works.

Chief Interchange Car Inspectors' and Car Foremen's Association.—A. S. Sternberg, Belt Railway, Clearing Station, Chicago. Annual convention, Hotel Sherman, Chicago, September 22-24.

Cincinnati Railway Club.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meetings, second Tuesday, February, May, September and November. Next meeting September 8. Humorist talk on general railroading by Dusty Miller. Dinner party and address by Mr. Miller.

Cleveland Steam Railway Club.—F. L. Frericks, 14416 Adler Ave., Cleveland, Ohio. Meeting first Monday each month except July, August and September, at Hotel Cleveland, Public Square, Cleveland.

International Railroad Master Blacksmiths' Association.—W. J. Mayer, Michigan Central, 2347 Clark Ave., Detroit, Mich.

International Railway Fuel Association.—J. B. Hutchinson, 1809 Capitol Ave., Omaha, Neb. Next meeting May 11-14, 1926, Hotel Sherman, Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W Wabash Ave., Winona, Minn. Annual convention September 8-11, Hotel Sherman, Chicago.

Master Boiler Makers' Association.—Harry D. Vought, 26 Cortlandt St., New York, N. Y.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meeting second Tuesday in month, except June, July, August and September. Copley-Plaza Hotel, Boston, Mass.

New York Railroad Club.—H. D. Vought 26 Cortlandt St., New York. Meeting third Friday each month, except June, July and August, at 29 West Thirty-ninth St., New York.

Niagara Frontier Car Men's Association.—George A. J. Hochgreb, 625 Brisbane Building, Buffalo, N. Y. Regular meetings, January, March, May, September and October.

Pacific Railway Club.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Regular meetings, second Thursday of each month in San Francisco and Oakland, Cal., alternately.

Railway Club of Greenville.—F. D. Castor, clerk, maintenance of way department, Bessemer & Lake Erie, Greenville, Pa. Meeting last Friday of each month, except June, July and August.

Railway Club of Pittsburgh.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Regular meeting fourth Thursday in month, except June, July and August. Fort Pitt Hotel, Pittsburgh, Pa.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, second Friday in each month, except June, July and August.

Southeastern Carmen's Interchange Association.—J. E. Rubley, Southern Railway shops, Atlanta, Ga.

Travelling Engineers' Association.—W. O. Thompson, 1177 East Ninety-eighth St., Cleveland, Ohio. Annual meeting, September 15-18, 1925, Chicago.

Western Railway Club.—Bruce V. Crandall, 189 West Madison St., Chicago. Regular meetings, third Monday in each month, except June, July and August.

Supply Trade Notes

The General American Tank Car Corporation has removed its Los Angeles office from the Pacific Finance building to the Bartlett building.

The Union Tank Car Company is constructing repair shops, including a foundry, a machine shop, a power plant and a wheel shop, at Whiting, Ind.

John P. Bourke, eastern sales manager of the Ewald Iron Company, Louisville, Ky., has been elected a vice-president, with office at 33 West Forty-second street, New York City.

The R. K. LeBlond Machine Tool Company, Cincinnati, Ohio, has appointed the Federal Machinery Sales Company, Chicago, its sales representative for Chicago and adjoining territory.

Robert L. Nutt, Jr., Norfolk, Va., now represents Robert H. Blackall of Pittsburgh and New York for the sale of the Lawson pipe wrench to railroads in Norfolk and adjacent territory.

Arthur Jackson, 32 Glenholme avenue, Toronto, Ontario, has been appointed sales representative for Ontario and Eastern Canada of the Gibb Welding Machines Company, Bay City, Mich.

Harold Bates has joined the sales department of the Bridgeport Brass Company, Bridgeport, Conn. He will be engaged with matters pertaining particularly to sales organization and research.

Percy M. Brotherhood, formerly first vice-president of Manning, Maxwell & Moore, Inc., has opened an office at 25 Church street, New York City specializing in machine tools and specialties.

The Ohio Locomotive Crane Company, Bucyrus, Ohio, has purchased the Bucyrus plant of the Ohio Steel Foundries, Lima, Ohio, and will remodel the plant for the production of gray iron castings.

The Tennessee Engineering & Sales Company, 510 Burwell building, Knoxville, Tenn., has been appointed agent in part of Tennessee and Kentucky within a working radius of the city of Knoxville, for the Roller-Smith Company, New York.

The Cummings Car & Coach Company has been incorporated, with headquarters at 111 W. Monroe street, Chicago, to manufacture railway appliances. The company has a capital of $200,000, and has issued 1,000 shares of no par value stock. Walter J. Cummings, O. N. Hebner and John T. Giblin are the incorporators.

William J. Miskella has opened an office and laboratory at 1164 West Twenty-second street, Chicago, where he will specialize as a consulting engineer on lacquer, japan and enamel finishing problems. Mr. Miskella was formerly for many years branch manager of the De Vilbiss Manufacturing Company and president of the Lamberson Japanning Company.

The Air Reduction Sales Company, New York City, has purchased the assets and assumed the liabilities of the Gas Tank Recharging Company, incorporated in 1913. The Gas Tank Recharging Company owned and operated acetylene plants at Milwaukee, Wis., and Bettendorf, Iowa; and a carbide plant at Keokuk, Iowa, where they manufactured Sun-Lite brand carbide.

The Lenoir Car Works, Lenoir City, Tenn., has placed a contract with the Converse Bridge & Steel Company, Chattanooga, Tenn., for the construction of car erecting and steel fabricating shops 800 ft. by 125 ft. to take the place of a structure recently burned. The new building, which will be of steel construction, will be completed in 90 days and will be equipped with new machinery.

E. E. Goodwillie, district sales agent of the Bethlehem Steel Company, with headquarters at Chicago, has been appointed steel sales representative on the Pacific Coast, with headquarters in San Francisco, Cal., to succeed Leigh B. Morris, resigned. John F. Hennessy, district sales agent, with headquarters at Cincinnati, Ohio, has been transferred to Chicago, to succeed Mr. Goodwillie.

Brownrigg L. Norton, for the past two years representative at New York of the Western Railway Equipment Company and the Railway Devices Company, of St. Louis, Mo., has resigned the above representation to become sales agent of the Scullin Steel

Company, St. Louis. Mr. Norton's headquarters will be in the New York office of the company at Room 2050, Grand Central Terminal, New York.

The Haynes Stellite Company, New York, manufacturers of metal cutting tools has completed concentration of the company's activities at its plant at Kokomo, Ind. All service in connection with its products will hereafter be extended direct from the plant. The headquarters for administration, sales and engineering activities will be at Kokomo, conducted under the direction of C. G. Chisholm, general manager.

The More-Jones Brass & Metal Company is completing the erection at St. Louis, Mo., of a modern and large plant which will be devoted to the production of brass and bronze castings. The plant will consist of a foundry and machine shop which will provide a total floor area of 157,000 sq. ft. The railroad facilities for the plant will consist of a double spur track for loading and unloading 10 cars and a yard capacity of 20 cars.

The Prentiss Vise Company, New York, has bought the Henry Cheney Hammer Corporation, of Little Falls, N. Y., complete, and will continue to operate the plant at Little Falls with the same personnel that has been there for some time. The Cheney hammers will in future be sold through the Prentiss Vise Company, and the hammer plant will be operated as the Cheney Hammer division of the Prentiss Vise Company.

William McConway, president of the McConway & Torley Company, died on July 28, in St. Francis hospital, Pittsburgh, Pa. Mr. McConway was born in Ireland on February 14, 1842. He came to the United States in 1849 and attended the public schools until he was 12, when he went to work with the Novelty Iron Works. Six months later he entered the service of Olhausen & Crawford, manufacturers of malleable iron castings, remaining with that company until September, 1861, when he entered the United States Army as a private and served through the Civil War; during this service he was promoted to sergeant-major, and in July, 1863, was commissioned a second lieutenant. In September, 1864, he returned to civil life and resumed his employment with Olhausen & Crawford, in 1866 becoming a junior partner of this firm. In 1869 he organized the present business under the firm name of Lewis & Co. and became its general manager. The following year the name was changed to the McConway & Torley Company, and in 1892 the firm was incorporated. Mr. McConway was a pioneer in the development of the automatic coupler. He had served as a director of numerous corporations including that of the Westinghouse Electric & Manufacturing Company. He was also a trustee of the Carnegie Institute and the Carnegie Institute of Technology.

William McConway

The Dearborn Chemical Company, Chicago, is constructing a concrete and brick building as an extension to its plant which will add 10,000 sq. ft. of floor space. New power plant equipment will consist of return tubular boilers, each equipped with automatic feed stokers, and overhead concrete coal bunkers of 150-ton capacity to be filled by a conveyor which will also handle the ashes. The cost of the new plant will be in the neighborhood of $150,000.

The Simplex Semimetallic Packing Company, Pittsburgh, Pa., has acquired all patents, patent rights, trade marks, etc., of the Mason Semi Metallic Packing Company, of Pittsburgh, manufacturers of air pump and piston packings. The Simplex company has discontinued the office of the Mason Packing Company which was located in the Renshaw building and has opened offices in the Oliver building, Pittsburgh, where the business of the company will be conducted.

H. G. Mastin has been appointed representative in the sales department of the Locomotive Stoker Company, eastern district, with headquarters at New York City. Mr. Mastin was born in December, 1887, at Millbrook, N. Y. He served from 1906 to 1918 on the New York, Ontario & Western consecutively as locomotive fireman, traveling fireman and assistant road foreman of engines, and since October, 1918, as mechanical expert for the Locomotive Stoker Company.

The General American Tank Car Corporation, Chicago, has made the following appointments in its tank car sales department: R. J. Sharpe, general western sales manager, with headquarters at Tulsa, Okla.; M. A. Sticelber, sales representative, Tulsa, Okla.; Bennett Epstein, general eastern sales manager, New York City; R. T. Musser, Pacific Coast sales manager, with headquarters at Los Angeles and San Francisco, Cal., and Z. R. Simon, southern sales manager, New Orleans, La.

W. H. Davis, service engineer of the Universal Packing & Service Company, Chicago, has been promoted to general sales manager, with headquarters at Chicago. R. C. Blakslee, of the testing department of the Chicago, Rock Island & Pacific, with headquarters at Silvis, Ill., has resigned to become a service engineer for the Universal Packing & Service Company. T. P. Williams and J. D. Herr, formerly associated with the National Waste Company at Philadelphia, and W. M. Gibbs, formerly employed by the same company at Chicago, have been appointed service engineers of the Universal Packing & Service Company.

The Bird-Archer Company has opened a new plant in Chicago for the manufacture of boiler water treatment chemicals. The building is of brick and steel construction and with ground owned and available will permit of a 500 per cent expansion. The locomotive anti-foaming compound department is capable with present equipment of turning out 30,000 lb. per day while the department allocated to the manufacture of locomotive anti-scaling and anti-pitting compounds in solid form has a capacity of approximately 20,000 lb. per day. Arrangements for a branch laboratory in connection with the new plant will soon be consummated.

E. J. Tierney, in the service of the mechanical engineer's office of the Missouri Pacific, and George P. Hoffman, general car foreman of the Baltimore & Ohio, at Baltimore, Md., have been appointed district sales managers of the Grip Nut Company, Chicago. Mr. Tierney was born at Attica, N. Y., on October 20, 1888, and was educated in the schools at Attica and Scranton. He entered the service of the Erie Railroad as a water boy and in 1902 went to the Missouri-Kansas-Texas as a machinist apprentice. In 1906 he went to the Missouri Pacific as a machinist. He subsequently served in the same capacity on the Colorado & Southern; Southern Pacific; Chicago, Burlington & Quincy; Galveston, Harrisburg & San Antonio and then returned to the Missouri Pacific as shop draftsman. In 1908 he returned to the Missouri-Kansas-Texas as mechanical draftsman, and was promoted in 1913 to chief draftsman and general inspector of the Missouri-Kansas-Texas lines, which position he left to join the United States Army in France, where he served as a second lieutenant in the engineering corps. assigned to duty in Russia on the Trans-Siberian railroad. He subsequently returned to France where he served in the army for one and one-half years. After his discharge from the army, he returned to the Missouri-Kansas-Texas. In 1920 he was appointed mechanical engineer of the Louisiana & Arkansas, and two years later served in the same capacity with the Midland Valley. He subsequently resigned to return to the Missouri Pacific as inspector, gang foreman and general draftsman, which position he held until his appointment with the Grip Nut Company, as above noted. Mr. Tierney will be located in Chicago. Mr. Hoffman was born at Meyersdale, Pa., on June 28, 1889, and was educated in the public schools and the Tri-State business college in Cumberland, Md. On September 1, 1907, he entered the service of the Baltimore & Ohio as an apprentice in the car department, and in 1912, was appointed supervisor, which position he held until he entered the United States Army, and served two years in the World War with the army in France. He entered the service as a private and was promoted to a commission. After receiving his discharge he returned to America and remained in government service as supervisor of car repairs with the Railroad Administration until he was reappointed general car foreman of the Baltimore & Ohio at Baltimore, which position he resigned to enter the service of the Grip Nut Company. Mr. Hoffman in his new position will be located in the East.

Trade Publications

Gear catalogue.—Standard stock gear catalogue No. 42, illustrating spur gears, bevels, mitres, internal gears, worms, worm gears and spiral gears, has been issued by the Charles Bond Company, Philadelphia, Pa.

Pipe threading machinery.—The Landis Machine Company, Inc., Waynesboro, Pa., has issued catalogue No. 29 descriptive and illustrative of its pipe threading and cutting machines, pipe and nipple threading machines and chaser grinder.

Carbide lights.—Portable carbide lights for night construction are described in a 26-page booklet issued by the Alexander Milburn Company, Baltimore, Md. These lights are particularly suited for contractors, railway mines and quarries.

Galvanum paint.—A color card and a folder descriptive of Galvanum paint have been issued by the Goheen Corporation of New Jersey, Newark, N. J. This paint is applied directly to galvanized iron without the aid of an acid wash or primer of any sort, and no weathering of the metal is necessary.

Vacuum recorders.—Vacuum recorders which operate on the mercury column principle and employ no moving parts, springs or diaphragms, are covered in Bulletin No. 140 recently issued by the Uehling Instrument Company, Paterson, N. J. Full size reproductions of sections of typical vacuum charts show the legibility of this instrument.

Oxwelding and cutting.—"Precautions and safe practices" is the title of a 16-page brochure which has recently been issued by the Oxweld Acetylene Company, Long Island City. This pamphlet has been prepared to provide a brief and practical list of "do's and don't's" so men may understand the precautions and care which are necessary to the safe and economical use of the oxy-acetylene process.

Oxyacetylene process.—"Answers to questions about the oxy-acetylene process," a recent publication of the Air Reduction Sales Company, New York, is intended to supply in convenient pocket form some of the information often requested on the principles of the oxyacetylene process, oxygen, care of oxygen cylinders, acetylene, care of acetylene cylinders, equipment, welding, cutting and the company.

Cranes and foundry equipment.—A black leather binder made up of individual catalogues containing up-to-date information on cranes, cupolas, ladles, tumbling mills, core oven equipment, trucks, turntables and trolley systems, air hoists, elevators, side-blow steel converter, and brass foundry equipment, has been issued by the Whiting Corporation, Harvey, Ill. Thumb index cards are inserted between each of the catalogues which are of letter size, 8½ in. by 11 in.

Motor bearings.—"The care of railway motor bearings," publication GEA-60 of the General Electric Company, Schenectady, New York, gives directions for the correct lubrication of sleeve type bearings, considering both armature and axle linings. Brass and babbitt, and iron and babbitt linings are referred to, and instructions are given for rebabbitting bearings. Three photographs showing methods of lubrication, as well as a table showing proper oil levels, are included.

Drop door locks.—A number of application drawings of Wine drop door locks for the guidance of the designing engineer in working out applications to suit various requirements, are contained in an attractive catalogue, No. 41, which has been issued by the Wine Railway Appliance Company, Toledo, Ohio. The catalogue, which contains 40 pages, also features a number of cars equipped with the drop door locks, and vividly shows the method of applying the device and the method of closing the doors on various types of hopper cars.

Absorbo.—A system of isolation of machinery vibration known as Absorbo, is described in a four-page circular issued by the Cork Foundation Company, New York. This material, adaptable to a large variety of machinery, including power plant apparatus, is a natural cork product made in strips 1½ in. thick, which are set in rigid steel frames with lateral braces under individual machines or under entire areas where machines are set closely together. When properly applied, vibration set up by moving machinery is greatly reduced or entirely eliminated.

Stokers.—Detroit underfeed stokers of the single retort type are described in an attractive 32-page bulletin, No. 1018, just issued by the Detroit Stoker Company, Detroit, Mich. Among other items of outstanding interest to combustion engineers, the bulletin contains a number of fuel bed cross sections showing conditions of the fire with respect to air distribution and movement toward the dumps. A section of the book is devoted to the application of the stoker to both low and high set boilers and another section shows how twin settings serve very large boilers.

Automatic controllers.—Automatic controllers for temperature, pressure, humidity, liquid level, condensation and other factors which are important to the success of industrial processes, are described in the new catalogue issued by the C. J. Tagliabue Manufacturing Company, Brooklyn, N. Y. The catalogue resembles preceding editions, but is larger and several more instruments are listed. The importance of automatic control in various industries is stressed in a six-page introduction which is entirely new. An interesting discussion of automatic control problems in a number of industries follows, and many actual cases are cited.

Locomotive feedwater heaters.—The Superheater Company, New York, has just issued a new catalogue describing and illustrating the theory, construction and application of the Elesco non-contact type of locomotive feedwater heater. The catalogue, which contains 24, 8¼-in. by 11-in. pages, is a treatise on steam production and its utilization in locomotives. With the aid of diagrams accompanied by test, the increase in efficiency of the locomotive through the application of a feedwater heater is explained and what this amounts to in actual dollars and cents under varying conditions. The latest designs are illustrated and many typical installations shown.

Shop handbook on tool steel.—Tool steel that is purchased from a mill or a warehouse is not, as a rule, a finished product. It is for this reason that Joseph T. Ryerson & Son, Inc., Chicago, has prepared a book for the tool steel user as he is the one who must change the tool steel from a semi-finished to a finished product. For the successful carrying out of this operation certain definite information is necessary. This book, which contains 80 pages with illustrations and tables, presents to the purchasing agent, superintendent or the tool maker a technical subject treated in a non-technical way. The book contains chapters on the following subjects: Choosing the proper steel for the job; heat treatment of tool steel; heating tool steel; heating equipment; forging tool steel; annealing; quenching; tempering; testing tool steel; heat measurement; grinding. This book should be in the hands of every user of tool steel as it contains valuable information which is generally found only in highly technical books.

Valves and fittings.—A comprehensive catalogue, No. 83, containing more than 700 pages descriptive of a large variety of valves, fittings and tools, wrought pipe and supplies for steam, water, gas, oil and air installations, is being issued by the Walworth Manufacturing Company, Boston, Mass. The new catalogue is bound in cloth and contains many new devices, among which is included a line of hydraulic steel and iron flanged fittings for 800-lb. cold water working pressure, known as the American hydraulic standard. The new Sigma cast steel fittings and valves are shown in a section which includes also the complete line of drop forged steel fittings. Other items of recent development are pipe hangers and brackets, tested air brake elbows and tees, double disc gate valves for use in oil refinery and pipe line service, an 800-lb. American standard steel and iron gate valve, a new design of yoke top iron body globe, angle and cross valves and steel and iron yoke top globe angle and swing check valves for 250-lb. working steam pressure. Information on a new line of needle point globe and angle valves for fuel oil and gasoline is given, and stop and waste globe valves are listed in ½-in. and ¾-in. sizes. Sections are devoted to specialties and engine and boiler trimmings. A large variety of wrenches and other tools is shown, and there are pages listing drainage and soil pipe fittings, ammonia fittings and valves and heating material. Tables of useful data, as well as telegraphic codes, are included. Certain sizes of screw and flanged fittings and flanges, valves, cocks, etc., have been eliminated from the catalogue, but are carried in the list of special made-to-order items.

Personal Mention

General

F. M. Reed has been appointed motive power inspector, office of master mechanic, of the Eastern region of the Pennsylvania, with headquarters at New York.

W. P. Lambert has been appointed special assistant of the Central of New Jersey, with duties to be assigned by the superintendent of motive power and equipment.

G. S. Webb has been appointed motive power inspector, office of general superintendent of motive power, of the Eastern region of the Pennsylvania, with headquarters at Philadelphia, Pa.

H. M. Warden, superintendent of the locomotive department of the Missouri-Kansas-Texas, has been appointed mechanical superintendent, with headquarters at Parsons, Kans., succeeding M. C. M. Hatch, resigned.

Master Mechanics and Road Foremen

W. H. Prindall, master mechanic of the Connecticut river division of the Boston & Maine, has been transferred to the Southern division, with headquarters at Concord, N. H.

Charles W. Extrand, formerly locomotive engineer, St. Paul Division of the Northern Pacific, has been appointed road foreman of engines, with headquarters at Minneapolis, Minn.

D. J. Ayers, master mechanic of the White Mountains-Passumpsic division of the Boston & Maine, has had his jurisdiction extended to include also the Connecticut river division.

F. A. Graham, traveling engineer of the New York division of the Pennsylvania, has been promoted to assistant road foreman of engines of the same division, succeeding W. M. Rue, deceased.

H. A. Bliss, master mechanic of the Southern division of the Boston & Maine, has been transferred in a similar capacity to the Fitchburg-Berkshire division, with headquarters at East Dearfield, Mass.

Shop and Enginehouse

George H. Massy has been promoted to foreman of the Central of New Jersey at the Elizabethport, N. J., enginehouse.

John J. Martin has been promoted to foreman of the Central of New Jersey at the Phillipsburg, Pa., enginehouse, succeeding George H. Massy.

V. N. Potts, general foreman of the International-Great Northern at Mart, Tex., has been transferred as general foreman to Houston, Tex.

S. J. Starke, roundhouse foreman of the International-Great Northern at San Antonio, Tex., has been promoted to general foreman, with headquarters at Mart, Tex., succeeding V. N. Potts.

H. C. Venter, general foreman, locomotive department, of the Southern Pacific at Sacramento, Cal., has been promoted to superintendent of shops, with the same headquarters, succeeding D. S. Watkins, who has retired.

Purchasing and Stores

W. R. Knauer has succeeded A. G. Follette as supervisor of the stores catalog of the Pennsylvania.

G. B. Hopkins has been appointed division storekeeper of the Gulf & Ship Island, with headquarters at Gulfport, Miss.

G. V. Green has been appointed purchasing agent of the Southern Pacific of Mexico, with headquarters at Tucson, Ariz.

R. J. Gable has been appointed division storekeeper of the Illinois Central at Mattoon, Ill., succeeding A. E. Walters.

F. L. Doss, division storekeeper of the Southern Pacific at Dunsmuir, Cal., has been transferred to Bakersfield, Cal., succeeding J. F. Brown.

E. H. Polk, district storekeeper of the Southern Pacific at West Oakland, Cal., has been transferred to Sacramento, Cal., in place of E. Harty.

J. G. Warnecke, division storekeeper of the Illinois Central at Centralia, Ill., has been transferred to Paducah, Ky., succeeding B. T. Adams.

M. E. Baile has been appointed district storekeeper of the Missouri Pacific, with headquarters at Kansas City, Mo., a newly created position.

A. E. Walters, division storekeeper of the Illinois Central at Mattoon, Ill., has been transferred to Centralia, Ill., succeeding J. G. Warnecke.

J. F. Brown, division storekeeper of the Southern Pacific at Bakersfield, Cal., has been transferred to Ogden, Utah, in place of H. W. Concannon.

H. W. Concannon, division storekeeper of the Southern Pacific at Ogden, Utah, has been promoted to district storekeeper at West Oakland, Cal., succeeding E. H. Polk.

A. J. Mello, purchasing agent of the San Diego & Arizona, has been appointed general storekeeper of the Pacific Fruit Express, with headquarters at San Francisco, Cal.

W. F. Naumann has been appointed division storekeeper of the Illinois Central, with headquarters at East St. Louis, Ill., succeeding W. A. Skinner, who has retired on pension.

E. Harty, district storekeeper of the Southern Pacific at Sacramento, Cal., has been promoted to assistant general storekeeper, with headquarters at San Francisco, a newly created position.

C. M. Barron, purchasing agent of the Cuba Railroad, has been appointed general purchasing agent of the Consolidated Railroads of Cuba, with headquarters at Grand Central Terminal, New York.

Joseph V. Miller has been appointed assistant general storekeeper of the Chicago, Milwaukee & St. Paul. He was formerly western sales representative of the Prime Manufacturing Company, Milwaukee, Wis.

F. J. O'Connor, assistant storekeeper of the Chicago, Milwaukee & St. Paul at Milwaukee, Wis., has been promoted to assistant purchasing agent, with headquarters at Chicago, succeeding G. R. Cooke, who has resigned.

B. T. Adams, division storekeeper of the Illinois Central, with headquarters at Paducah, Ky., has been promoted to assistant general storekeeper of the Southern lines, the Yazoo & Mississippi Valley and the Gulf & Ship Island, with headquarters at Memphis, Tenn., succeeding W. D. Stokes, deceased.

F. W. Mahl, director of purchases of the Southern Pacific, whose headquarters were recently changed from New York to San Francisco, has now been appointed general purchasing agent, with headquarters in the latter city. He will have general supervision of the purchasing and stores departments of the company.

Car Department

James W. Gibbons has been appointed general foreman, passenger car department, of the Atchison, Topeka & Santa Fe, with headquarters at Topeka, Kans., succeeding H. J. Neiswinter, retired. Mr. Gibbons was born in St. Louis, Mo., and educated in the grammar schools at Decatur, Ill., his first railroad work being with the Wabash. He has been an employee of the Santa Fe since August, 1887, and for the past two years assistant general foreman. In addition to his duties as general foreman, passenger car department, Mr. Gibbons retains his duties as supervisor of all paint matters of the mechanical department.

Obituary

Allan Bourn, formerly purchasing agent of the Michigan Central, died at Dorset, Vt., on July 13.

W. D. Stokes, assistant general storekeeper of the Illinois Central, with headquarters at Memphis, Tenn., died at Jackson, Miss., on July 20.

R. H. Briggs, formerly master mechanic of the St. Louis-San Francisco at Memphis, Tenn., who retired from active service in 1913, died at Memphis on July 3.

Railway Mechanical Engineer

Vol. 99 October, 1925 No. 10

Using the Railway Mechanical Engineer

In the September issue we commented upon practical ways in which some of the mechanical department officers are utilizing the *Railway Mechanical Engineer*. Our comments apparently struck a responsive chord, because we have since learned of several officers who are regularly asking at least some of their subordinates to read certain specific articles and advise whether the principles, methods or practices described have been tried, or whether better results can be secured in other ways. One superintendent motive power in particular, asked all of his subordinates, down to and including the foremen, to tell what they thought of the first two prize articles on "The foreman and his responsibility" and the correspondence in the August number relating to "Bill Brown's" first prize article. In the neighborhood of 175 reports were received indicating that his associates had closely read all of these articles and outlining the extent to which they agreed or disagreed with various suggestions which were made. It is difficult to estimate the results of the careful study of these articles on even one railroad by all of those who occupy positions of leadership in the mechanical department. Does anyone question the great importance or value of making use of the *Railway Mechanical Engineer* in this way? Would it be worth while to have some one person on the staff of the mechanical superintendent select those articles of special merit which are of interest to different classes of foremen and officers in the mechanical department and ask for a report on whether the ideas suggested are in use or could be applied to advantage?

Periodical shopping of freight cars

The *Railway Mechanical Engineer* has frequently commented on the lack of systematic methods of bringing in freight cars for general overhauling. Contrary to the practice with respect to locomotives by which a regular cycle of shoppings for classified repairs is established, most generally on a mileage basis, freight cars have been placed in the shop in a haphazard manner with little attention to regularity or the condition requirements for the most economical overall maintenance cost. It is very encouraging, therefore, to find at least one railroad which is giving much the same attention to the advance scheduling of the heavy repairs on its various series of freight cars that locomotives have long received. There are, no doubt, other railroads that are now giving this subject serious attention, but those who read the paper on the subject of the progressive system of freight car repairs presented by F. A. Starr at the convention of the Chief Interchange Car Inspectors' and Car Foremen's Association, which will be found on another page in this issue, will recognize that the Chesapeake & Ohio is doing a notable piece of work in combining the periodical shopping of its cars by series with such production methods in the shops as the segregation of the cars in each series, employment of the progressive system of shop operation, the specialization of shop forces and the scheduling system.

Mr. Starr's paper, since it deals primarily with that subject, places the greatest stress on the progressive system of putting the cars through the shops, and, indeed, it is this system which has made possible the application of the scheduling system, with its reduction of lost motion and waste supervisory effort, to freight car work. To the progressive system must also be credited the development of a regular program of periodical shopping because the fullest advantage of the progressive system could not be taken unless such a program were in force.

Probably the greatest difficulty encountered in any attempt to apply production methods to freight car repairs arises from the difficulty of providing the various shops on any railroad with a regular supply of cars of the same series, all of the same type of construction and the same age and, therefore, all requiring approximately the same type of material and operations in their rehabilitation or reconstruction. It is true that this is a real difficulty if an attempt is made to take the cars out of service without carefully laid plans having been developed well in advance of the beginning of the repair program. It is precisely at this point that the development of a regular program of periodical overhauling of each series of equipment becomes effective. When once established, it provides the basis on which equipment from the various series may be segregated in sufficient numbers to keep the shops regularly supplied. Indeed it may be said that such a program of periodical overhauling must be the foundation of any structure which has for its purpose the most freight car service for the least maintenance cost.

The foreman's qualifications

The article by W. J. Taylor which was submitted in the competition on "The foreman and his responsibility" and which appears elsewhere in this number, goes frankly to some of the roots of the question, approaching it, however, in quite a different way from the three prize articles which have already been published. Those who have followed these articles closely must recognize the fact that the great value of the competition lies not in any one of the articles, or in the first prize article, but in the group of articles as a whole. Moreover, many of the ideas which have been presented in the four articles which have already been published could very well be amplified and enlarged upon. Mr. Taylor, for instance, makes a very pertinent suggestion about stealing the ideas or suggestions made by subordinates or workers. Intimate contact with men in the ranks and many of the foremen and supervisory officers has emphasized the fact that nothing can do more to lower the morale or discourage ambitious

men than a foreman or officer who claims individual credit for good work or suggestions made by men under his charge. Such an attitude effectively discourages that constructive interest on the part of the men which is so necessary and desirable in the interests of the highest degree of efficiency.

Mr. Taylor in his description of an imaginary staff meeting has cleverly and tactfully touched upon one of the difficult situations which confront many of the foremen and subordinate supervisory officers; a situation, by the way, which has been magnified and thrown into the limelight on some roads on which works councils or organized co-operation have been established. It has been a bit embarrassing to many of the foremen who have consistently recommended detail improvements for a number of years, to have these improvements made when the facts were finally brought out in open council by representatives of the workers. If it were not such a serious problem in many shops, also, the fact that machine tools and equipment 30, 40, 50 or 60 years old are being used to repair 1925 equipment, could well be regarded as a joke. Unfortunately it is no laughing matter for those who have the responsibility of securing efficiency and output.

Among the other pertinent suggestions made by Mr. Taylor we cannot overlook the statement that "spoiling of work is generally the result of poor supervision." What would it not mean to the railroads if the full import of this statement could be driven home and profited by? Some of us will never forget that thorough, efficient superintendent of motive power, who has now passed on, who consistently declared that equally good results could be secured from day work, piece work, bonus or other systems, if those in charge understood just how a job should be done and just how much time should be required to do it—and he proved his assertion by conducting a large shop on a day work basis as efficiently and economically as any other railroad shop in the country. There was a minimum of spoiled work and it was because there was a maximum of efficient and intelligent supervision. There are many other things in Mr. Taylor's article that are worthy of comment, but we could not resist the temptation of making some reference to these three things, which in some ways stand out above the others.

Emphasis upon the human element

Sometimes we receive a severe jolt when we set up a measuring stick and see what rapid progress has quietly been made over a comparatively short period along more or less radical lines. There has been much discussion in recent years about personnel departments on railroads. Vice-presidents in charge of personnel have been appointed, or we have noted the quiet inauguration of personnel work under the direction of chief executives, who have added personnel experts to their staffs whose titles might mean anything.

Not a few mechanical department officers rubbed their eyes recently when the New York Railroad Club announced that the address at its September meeting would be made by Edwin F. Daley, assistant to superintendent of motive power and equipment—director of personnel—Delaware, Lackawanna & Western. Mr. Daley had had a thorough experience in the mechanical department work on the railroads, but was taken from one of the industries a year and a half ago to specialize on personnel matters in the mechanical department of the Lackawanna. So quietly and unobtrusively has this work been carried on that only a comparatively few people outside of the Lackawanna knew anything about it, and these were largely men from other roads who were interested in personnel matters.

Many people have assumed that Mr. Daley is the only man who has been specializing on this sort of work entirely within the mechanical department. It is quite probable, however, that if a careful survey were made, similar experts or officers might be found in the mechanical departments on a number of railroads. The name will not be found in the Pocket list of Railway Officials, but among the attendants at the meeting of the New York Railroad Club was David A. Henderson, who for the past two and a half years has been acting as personnel supervisor on the staff of the superintendent motive power of the Long Island. Mr. Henderson came to that road without railway experience, but with considerable training in personnel management in other industries.

Only last June, F. H. Becherer, general car inspector on the Boston & Maine, was made assistant to the mechanical superintendent. No general public announcement was made of the exact duties to be undertaken by Mr. Becherer, but it was understood that he would give all of his time to personnel matters and would be provided with such assistance as might be required. Mr. Becherer, while he was general car inspector, found an opportunity to assist in the promotion of foremen's clubs on the Boston & Maine and has always taken a keen interest in personnel matters, particularly along educational lines.

These developments are surface indications of a great and fairly rapid evolution which has been taking place in the railway field, and particularly in the mechanical departments of our railways. Emphasis today is being placed more and more on the importance of the human element in the organization. This has brought to the very forefront the necessity for the highest type of leadership on the part of the foremen and supervisory officers. It accounts to some extent for the great success of the *Railway Mechanical Engineer* competition on "The foreman and his responsibility." Such a competition announced even five years ago could not have attracted nearly as widespread interest or have inspired so large a number of contributions. It is doubtful, also, if the standard of the prize papers would have been anywhere nearly as high as those received last spring, the fourth of which is published in this number.

Traveling Engineers' Association hitting the ball

A résumé of the proceedings of the thirty-third annual convention of the Traveling Engineers' Association, held at Chicago recently as reported elsewhere in this issue, leads unavoidably to the conclusion that this association has increased the sphere of its influence and activity until now it is a real factor in providing efficient transportation service on steam railroads. In fact, it is "hitting the ball," and, since there is always room for improvement in associations of this kind, it is a pleasure to record that every indication points to an increased activity on the part of members of the Traveling Engineers' Association during the coming year and an even better convention in 1926.

Traveling engineers occupy a strategic position in the railroad transportation machine because of their intimate contact with operation. They are the supervisors most closely in touch with the men who move trains. All the equipment the railroads own can never earn a penny until it moves. It would be difficult to over-estimate the value to each railroad of its able traveling engineers who, by instruction, encouragement and practical example, influence locomotive enginemen and firemen to operate locomotives in either road or switching service more intensively and economically. If the traveling engineers on a single road are important, the influence of the Traveling Engineers' Association, embracing as it does members from practically every railroad in this country as well as

representatives from Canada and Mexico, is proportionately greater. The membership of the association in 1924-25 was 1,486, 252 members being reinstated during the past year and 105 new members added, making a total of 1,843 railroad men at present holding membership in the Traveling Engineers' Association. We do not recall one of the minor mechanical associations which goes into the discussion of reports as thoroughly as do the traveling engineers, and, as long as proper control of the discussion is maintained to keep it pertinent and on the subject, this feature should be encouraged.

The officers of the Traveling Engineers' Association during 1924-25, including the association's veteran secretary, W. O. Thompson, are to be congratulated on the success of the convention just passed. The prospects for an even better convention next year are most promising. The president elect, J. N. Clark, chief fuel supervisor of the Southern Pacific, brings to his office a wide experience in association work of this kind and he has already set a goal of 500 new members for the association in the coming year. There should be no difficulty in reaching this mark if the railroad men who are already members of the association catch a vision of its possibilities, do a little boosting, and go out individually after new members.

Plans for the convention in 1926 are already under way and a simple reading of the following list of subjects on the program without any attempt to analyze each, gives a good indication of what may be expected at the next convention: "The locomotive of today," "Smooth train handling," "Practical instruction for new firemen in combustion and locomotive operation," "The locomotive booster," "Locomotive availability in 100 per cent condition for operation," "How can the traveling engineer cover his growing job?" In addition, it is proposed to schedule the time for each report and its discussion so that members who are unable to attend the entire convention can arrange to be present on the day in which subjects of particular interest to them are to be presented.

All well wishers of the Traveling Engineers' Association will personally interest themselves in the next 12 months in securing new members, invest ungrudgingly a portion of their time in the preparation of committee reports if requested, boost the association to their superiors and make plans as far in advance as necessary for attendance at the convention next year.

New Books

A Manual of Locomotive Running Shed Management. *By Walter Paterson, staff department, London, Midland & Scottish Railway, Manchester, England, and Harry Webster, running department, London & North Eastern Railway, Lowestoft. 212 pages, illustrated. 6 in. by 9 in. Price $6.00. Published by Charles Griffin & Company, Limited, London, and J. B. Lippincott Company, Philadelphia.*

The object of this book is to present, in a convenient form, the essential information relative to the efficient management of steam railway locomotive and car shops as conducted in Great Britain. For the mechanical department officer engaged in railroad work in this country, considerable information in this book is of interest, especially the methods recommended for handling locomotive repairs. The authors have intentionally refrained from giving detailed descriptions of shop processes and operations, but have included descriptions of engine-house equipment and practice. It has been written primarily as an introductory manual for the use of junior officers and foremen in charge of departments.

It contains 13 chapters, with 44 illustrations, discussing such subjects as the organization of the staff and functions of its various members, personnel and employee welfare, stores department organization and management, fuel conservation, computation of locomotive mileage, locomotive and coach cleaning, locomotive and car repairs, causes and remedies for engine failures, methods used in handling wrecks, and the utilization of waste material. A number of tables are also given in an appendix in the back of the book showing the approximate temperature of a fire as indicated by its appearance, the approximate temperature of a car journal as indicated by its appearance, the strength of chains, capacity of water tanks, the delivery of injectors in gallons per hour, etc. Descriptions of a number of jigs and tools suitable for engine-house and wrecking service are given in the chapters devoted to locomotive repairs and break-downs.

Tests for Railway Material and Equipment. *By Henry Knauer, 257 pages, illustrated, 4¾ in. by 7½ in. Price $3.00. Published by the Simmons-Boardman Publishing Co., 30 Church Street, New York.*

The material contained in this volume is elementary in its scope and is intended for those taking up testing work in the laboratory and for those in the shops aspiring to engage in inspection of railway materials in the field. The tests are explained in such a clear, concise manner that a novice in this work should experience no trouble in grasping the fundamentals necessary for a successful laboratory analysis. The phraseology is such that all calculations and arithmetical substitutions are readily comprehended without recourse to chemistry or higher mathematics.

The first two chapters are devoted to the explanation of the nature of a test and with the methods and importance of recording the results of the findings. The next two chapters go into a detailed explanation of water and the treatment of the various mineral and organic compounds which may be found in it to cause trouble, particularly in a locomotive boiler. For a necessarily brief treatment, this particular subject is well handled. It is followed by several chapters dealing with all the tests required to determine the quality of paints and varnishes. Various oils and greases are briefly covered. More information on these materials should have been included but the reader can obtain an idea of the fundamental requirements of a good oil and grease. Chapter X contains a list of nine mechanical materials which the author quickly passed over with a few elementary remarks. The various laboratory tests to determine the quality of rubber goods and cement are explained in a very thorough manner. Chapter XIV contains four pages on the subject of cast iron. Considerable more space could have been devoted to this important subject. The chapters on wrought iron and steel products are well done and the chapters dealing with tension, hardness, fuel heat value tests and flue gas analysis are well worth reading for those handling these tests in the laboratory. The chapters dealing with the quality of steam and steam boiler tests and the methods of determining indicated and brake horsepower contain elementary information for novices interested in these tests. The last four chapters touch briefly on the subjects of the calculation of the test results of a steam engine, power reverse gear, locomotive road tests and tonnage rating tests.

The author omitted from his book any information pertaining to the testing of tender and car wheels, locomotive wheel centers and tires, glass, copper bearing steel, sheet metal, creosote for wood preserving, lumber and the testing of electric light bulbs and wire. These are essential railway materials and to make the book comprehensive should have received the same consideration as those actually covered.

In writing this book the author has inadvertently limited its usefulness by not considering the testing of material from the standpoint of the material inspector in the field. These men are always anxious to obtain any information which will aid them to make a thorough inspection of the materials they are called upon to inspect thereby protecting their interests as well as those of the railroad which they represent.

The elementary nature of the volume makes it suitable for the novice entering the testing laboratory and for the shopman whose desire is to take up the testing and inspection of materials.

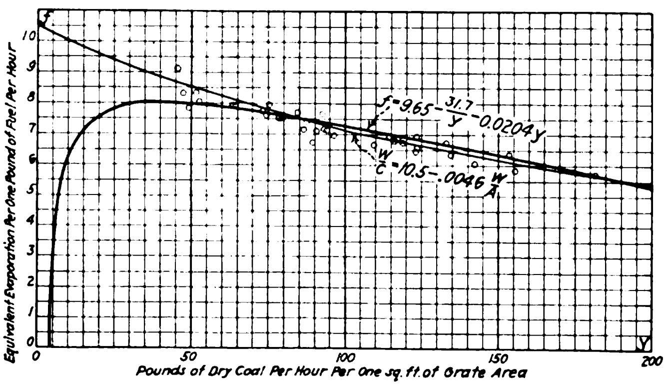
What Our Readers Think

The evaporative capacity of locomotives

ALTOONA, PA.

TO THE EDITOR:

The articles on "Evaporative capacity of locomotives," by Alexander P. Poperev, are certainly worthy of serious study since they vary in principle from generally accepted methods used heretofore. The theory presented involves more calculations than those of Dr. Goss and Lawford H. Fry. All three theories are empirical and necessarily cover arbitrary assumptions based on locomotive tests. These arbitrary assumptions differ materially. The additional burden of calculations will be justified only if the results are more accurate. Therefore, careful comparison of results of calculations, with test data available, should



Curve plotted on Fig. 6 from Dr. Goss's formula for purpose of comparison with the Poperev curve

be made before discarding the simple method of Dr. Goss for the more complicated method.

Dr. Goss's method which I have used for more than 25 years, was found adequate for the purpose and agrees closely with test results. It is true, as stated by Mr. Poperev, that there are heat losses from various causes, that coal can be burned on the grate without using any steam or increasing boiler pressure; but such losses are in the nature of "standby losses" which are, invariably considered separately. It is possible to estimate from the B.t.u.'s in a pound of steam and in a pound of coal, the theoretical maximum rate of evaporation per pound of dry coal. Allowances for heat losses and for coal losses, due to grade of coal and method of firing, can be deducted. The coal losses vary as much as 30 per cent at very low rates of combustion, between hand-firing and stoker-firing, but at high rates of combustion are nearly equal. They also vary for different kinds of stokers. But these losses, apparently, do not affect the nature of the curve which represents equivalent evaporation per pound of coal within the range in which a locomotive is worked on the road. All of the many tests made indicate that this curve, when based on increasing water rates, is a straight line. It is certainly proper to make assumptions for these losses, subtract them from the theoretical rate and establish the ratio of equivalent evaporation to a pound of dry coal for different rates of evaporation or coal consumption; but such arbitrary assumptions must be checked by tests, the results of which usually show that discrepancies from the estimated results are due to the grade of coal, or method of firing, or both.

Mr. Poperev failed to show a comparison of the methods which he criticized with his own, but condemned the other methods for technical reasons, which seem to be questionable, since they obtain only outside the range of action of a locomotive doing useful work. For a study of the value of his theory, some of the figures in his article can be analyzed to check his summary statement in the September, 1925, issue of the *Railway Mechanical Engineer,* page 554, reading: "On the contrary, by applying the same analysis to expressions, 17 and 21, we fail to find any similar contradictions, which fact can be considered an additional proof that the basic expression, (6) from which these formulas are derived, is correct."

Above this statement appears Fig. 6, giving results taken from Dr. Goss's tests with Mr. Poperev's formula for these tests and a line representing that formula. Not having a copy of those tests at hand, I have taken some of the points representing individual tests, from which Dr. Goss's formula would be:

$$W/C = 10.5 - .0046W/A$$

in which A is the area of the grate in square feet.

This formula, which is based on the rate of steam generated, translated to a basis of coal used, gives the results:

Dry coal lb. per sq. ft. of grate per hr.	25	50	75	100	125	150	175	200
W/C	9.44	8.54	7.80	7.20	6.67	6.22	5.82	5.47

Referring to the chart, it will readily be noticed that if these values are transcribed on Fig. 6, the resulting curve fits the tests much better than the Poperev curve.

Using the same method on Fig. 5, page 554, for efficiency, Dr. Goss's method would indicate the formula

$$E = .855/(1 + .0072C)$$

The curve plotted from this formula again fits the tests much better.

In Fig. 1, page 488, of the August, 1925, *Railway Mechanical Engineer,* the formula for the top chart (B. & W.) boiler would be:

$$W/C = .236 - .0067W$$

for the center chart (Whitman's tests)

$$W/C = .257 - .0046W$$

and the bottom chart (F. R. R. test)

$$W/C = .16 - .0057W$$

It should be understood that since the formulas given above are based on the meager test data gleaned from the figures given with Mr. Poperev's articles, they are not necessarily accurate, but they do permit a comparison between the methods of Dr. Goss and Mr. Poperev.

Those interested in this subject may take the trouble to trace out the curves by these formulas. They will find that, by Dr. Goss's method, more accurate agreements with actual tests are obtained than by Mr. Poperev's more elaborate method. Hence, instead of having proved that the basic expression (6), from which his formulas are derived, is correct, he has presented evidence which enhances the value of Dr. Goss's method.

The Lawford H. Fry method has not been discussed in this letter, because his investigations were intended more for analysis of heat transfer and his assumptions for ratio of W/C are only incidental to that subject.

W. F. KIESEL, JR.,
Mechanical engineer, Pennsylvania Railroad.

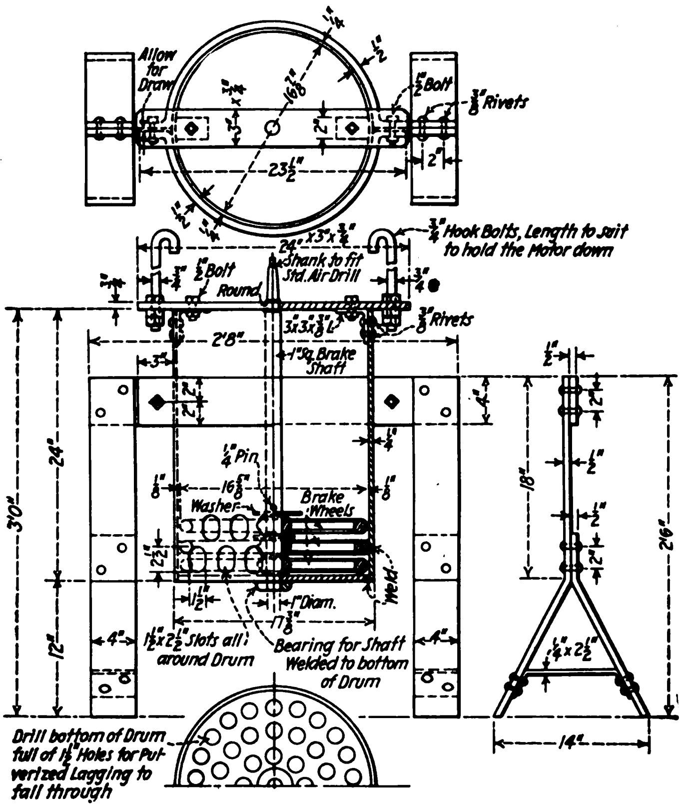
Reclaiming asbestos locomotive lagging

Milwaukee, Wis.

To the editor:

I was interested in the letter from Theo. Nygren on the reclaiming of asbestos locomotive lagging published on page 541 of the September, 1925, *Railway Mechanical Engineer*.

It is an ordinary occurrence on many roads to find an accumulation or surplus of second-hand and small pieces of boiler lagging. There is no market suitable to dispose



Grinder for powdering used asbestos lagging

of this material is scrap and it often-times happens that the surplus finds its way to the dump. This lagging represents a value practically as good as new material and it is not absolutely necessary that new lagging be used in all cases. The second-hand lagging can be powdered and reduced to a plastic state and together with short pieces can be used for filling in around locomotive cylinders, steam chest steam pipes, domes, back boiler heads and for stationary boilers, steam pipes, feedwater heaters, etc.

If the second-hand material is first used for these purposes, there will be little or none left for compressing into blocks and new blocks for locomotive boilers only need be purchased.

An inexpensive power operated tumbler or grinder for powdering second-hand lagging can be constructed in almost any railroad shop. The drawing illustrates such a device. An air drill is used to furnish the power. The pulverizing consists of three hand-brake wheels at the bottom of the container. The top and bottom wheels revolve with the square shaft and the center wheel is bored out sufficiently for the shaft to turn inside of the hub. This wheel is held stationary by welding the rim to the wheel of the container.

C. H. Bilty,

Mechanical engineer, Chicago, Milwaukee & St. Paul.

Burning the woodwork on steel underframes

Brownwood, Tex.

To the editor:

I have just received the September issue of the *Railway Mechanical Engineer* and shall try to answer the question asked by F. W. Bason as to how fire affects the steel underframes of box cars that have had the woodwork burned off. The effect on the steel underframes will be one of two things. If water is applied to hasten the cooling of the metal, you will crystalize the steel. Some parts may be heated more than others, and to replace them in service may cause failure. On the other hand, if the metal is allowed to cool slowly, it will be inclined to anneal or soften. There will likely be a weakening owing to the slight temper in the steel. The frame will sag more easily, but will not break owing to crystallization.

A Reader.

Treating hot driving boxes on modern power

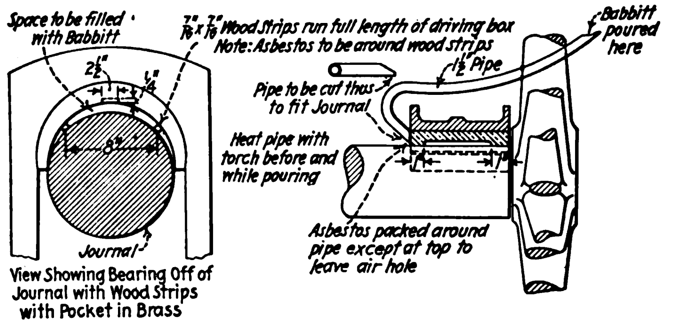
Peru, Indiana.

To the editor:

The problem of treating a hot driving box or journal is one that has caused the mechanical department worry and especially when the transportation department is calling for more power. Having had considerable experience in shop work and also some years of experience as an engineman, I believe that I can write on the subject.

Dropping wheels for a hot box is a big job, even if it is done in a modern enginehouse and if the facilities are not modern, it is much worse. Whenever we have a box that has been reported several times as running hot, and after packing the box and giving it close attention and still we do not get the desired results, we jack the box off the journal four or five inches and with an air hammer, cut a pocket in the crown brass 2½ in. wide and ¼ in. deep, being careful not to cut out the ends of the brass.

We then take two pieces of thin wood, thick enough so that the metal, when poured will be ⅜ in. or 7/16



Section view of the top of the box, showing how the babbitt is poured

in. thick. The box is then lowered on the journal and rests on the two pieces of wood, so that the bearing will stand about eight inches from the floor, after which it is packed with asbestos, a gate made and the babbit poured into the box. It is not necessary to remove the pieces of wood. Old piston packing having copper in it, that has been removed from superheated locomotives, gives a good bearing. This will apply to all driving boxes except the main box.

This method is something out of the ordinary and the work can be done in about six hours and the locomotive is ready to go into service.

J. E. Allen.

"Bill Brown" and "Top Sergeant"

One of "Bill Brown's" old shopmates backs him up— Day of bullying foreman is past

BECAUSE of the large number of mechanical association conventions which are reported in this issue, it is necessary to place severe restrictions upon the amount of space that we would like to devote to the "Bill Brown"—"Top Sergeant" controversy.

That "Bill Brown" in his first prize article in the June number painted an exceedingly clear picture of his early experiences, is indicated by the fact that two of his early shopmates recognized the picture and got in touch with "Bill," although he disguised his identity by writing under an assumed name. One of these men had neither seen nor heard of "Bill" for many years and wrote to us asking for information as to his whereabouts. The other one has been keeping in more or less close touch with "Bill" and has come to his aid under the signature of "Old Railroader," with a splendid contribution, which we take pleasure in passing on to our readers.

Mr. Maguire, whose letter we also print, suggests that "Top Sergeant" is a fake and that his contribution was probably prepared by one of our editors to, in effect, set up a "straw man" to knock down. It may be to the discredit of our editors that they were not ingenious enough to think of resorting to such a subterfuge, but we beg to assure Mr. Maguire and others who may have similar illusions, that "Top Sergeant's" letter was not written by a member of our staff and that its receipt not only came as a distinct surprise, but caused no little excitement in the editorial sanctum. As an effective answer to Mr. Maguire and others, we simply want to drive this question home. In thinking over your experiences and acquaintances, how many foremen and supervisors have you known or do you know who reflect in a greater or less degree the "Top Sergeant" attitude?

The letters from "Old Railroader" and Mr. Maguire follow:

A friend of "Bill Brown"

By "Old Railroader"

The first prize article on "The Foreman and His Responsibility" in your June issue by "Bill Brown" I read with unusual interest because its opening sentences about his having been a clarinet player in a certain band a number of years ago, and his graphic account of his foreman's interview with him, revealed to me that "Bill Brown" is none other than an old shopmate of mine, who is now one of my most intimate and esteemed friends.

That foreman of his, who was also my foreman, has long since gone the way of all the earth, and there is a Latin proverb, "Let nothing but good be said about the dead," but surely facts may be stated.

Well, I have read in your August number "Top Sergeant's" drastic criticism of "Bill Brown's" article, and from it I conclude that he is almost the exact counterpart of "Bill Brown's" foreman. This latter gentleman had a very exalted idea of his position. The king upon his throne, or the President in the White House was a small potato compared to a railroad shop foreman. He was "Sir Oracle and when he ope'd his mouth, let no dog bark." Yet he possessed no theoretical knowledge of mechanics. He was unable to make the simplest mechanical calculation. He scorned to read such publications as the *Railway Mechanical Engineer*. He perhaps had never heard of such a thing as a vernier, but he possessed one accomplishment. He was a rapid and beautiful writer, and the facility with which he could whip out his order book, and write an order for a man's discharge was only equaled by the facility with which Mr. "Top Sergeant" can show the gate to the man or men who do not please him. "Bill Brown's" foreman handled the apprentices in a way that would rejoice the heart of Mr. "Top Sergeant" and many a bright boy of sensitive nature he drove out of the shop by his harshness and cruelty.

How did he himself make out by his bull-dozing, ignorant brutality? Did he rise step by step till he reached the highest position in his line? No! He was put back to run a machine, and a sorry job he made of it. He jumped about like a bear on a hot gridiron and accomplished very little, while an elderly Scotchman near him accomplished a great deal. Yet the Scotchman was apparently slow and deliberate in his movements, but every move was in the right direction. Finally Mr. Ex-Foreman was discharged. He got a job overseeing the mixing of cement for the corporation. Then he went to work in a railroad shop in a neighboring city, and soon he died. Of course, we hope Mr. "Top Sergeant's" career will not end so ignominiously.

Mr. Editor, you spoke of Mr. "Top Sergeant" as "an old-fashioned, hard-boiled type of foreman." It is to be hoped he is the sole surviving member of the hard-boiled type of foreman.

"Bill Brown's" article breathes the gentler, more enlightened, more humane spirit of the present day. It recognizes the fact, for it is a fact, that better service can be obtained from men, by friendly, tactful handling, than by treating them as though they were mere "dumb driven cattle." His article reflects throughout his own splendid, large-hearted, common-sense personality.

In his suggestion of the new foreman calling his men together, and talking to them in the manner he outlines, he is in very good company. A newly-appointed president of a vast railway system, went from point to point on the system where large numbers of men were employed. He called them together in all their grime and addressing them in a friendly way, told them that the success of the system depended on the faithful and hearty co-operation of every employee with the management.

His suggestion as to the treatment of the new employee, which is humane and considerate, must meet with the approval of every right thinking person. No foreman can size up a new man in 20 minutes. Some men, and good men, too, experience on beginning work in a strange shop, something akin to "stage fright." They imagine they are the objects of critical attention. They are self-conscious and for a time are not their true selves at all. "Bill Brown" takes note of this and would help them through the period of strangeness.

His remarks on new tools or machinery, on the sales engineer, on the conservation of material, are all good and sensible, but the writer particularly likes what he says about the attitude of the foreman towards the apprentices. Despite the sneers of Mr. "Top Sergeant" it is

in line with what is being done by great railway systems —the Santa Fe, for instance—to train and educate their apprentices. It is being more and more recognized that hands are more skilful and efficient when directed by well-trained brains.

Mr. Editor, it was a pleasure to me to read this article from the pen of my old friend, "Bill Brown." It meets with my approval, for it expresses my own sentiments better than I could possibly have expressed them, and the fact that you saw fit to award it the first prize, shows that it meets with your approval also.

Foreman must prove worth as a leader

By George T. Maguire

Boiler inspector and gang leader, Delaware & Hudson, Whitehall, N. Y.

If publicity leads to fame, "Bill Brown" is due for a place in industry's "Hall of Fame." He sure did "start something."

In presenting my personal views on the subject of his article, I cannot help including my views on the article of criticism offered by the "hard boiled" foreman who, to make himself sound "hard boiled," appropriated the nom de plume, "Top Sergeant." At the start let me state that I firmly believe that the article was written by the "top kick" (whom I'll wager is employed, not as a foreman but as an editorial writer) to purposely prolong the discussion of Brown's article. That it will fulfill its purpose, I have no vestige of doubt. If this writer really tried to increase his hardness by calling himself "Top Sergeant" let it be understood that the title is a misnomer. The war tamed the hard boiled "tops," as modern practice in industry has tamed the bully foreman.

Regarding a foreman's expectation of receiving thanks from a workman. Why should a workman thank the foreman? What foreman worthy of trust would approve a raise in the pay of a workman if that man was not deserving? And if a man is deserving of the increase, will it not reflect creditably upon the foreman? Does it not show that he has made another man more efficient? Therefore the increase is a 50-50 proposition. It means that the company is showing its approval of the foreman's system of increasing production, for increased production is increased efficiency and the foreman is showing his appreciation to the workman for making the increase possible. Need the man be thankful in words to the foreman? Will not a continued effort mean more than any number of words of thanks? In this case the "Top Sergeant" would be holding grievances and this according to his own words would eventually result in the "canning" of the workman. Would he be a competent foreman in dispensing with the services of a man who has proven worthy of a raise, simply because he forgot to say "thanks." How much would he save for the company?

I wonder just what the "hard boiled" foreman means by "he man." Does he mean a man of massive proportions whose remarkable strength is apparent but whose lack of reasoning power is appalling? Roosevelt was called the "Red blooded he man President"; did he think only of himself and his personal viewpoint?

Then comes the "top's" views on railway journals. What a fraud this man turns out to be. What man ever advanced from apprentice to journeyman unaided? Perhaps our "top" was born with all his knowledge. If we can advance unaided why not start as superintendents of motive power or master mechanics at least? Why be a mere foreman. Let us suppose our hardboiled foreman to be about fifty; he perhaps has thirty-five years' service on the road, say twenty years as a foreman. He was a foreman in 1905 when the Walschaert valve gear was brought to this country, when superheated steam was born, when the No. 6 E. T. air brake was put on the market. Who taught him what he knows about them? What does he know of welding methods, of three cylinder engines, unless he has read of them in journals or has had them explained to him by those who have read these journals, or who have been sent to help him by the builders? He is a blood brother of the boilermaker who continues to bead flues by hand because the pneumatic hammer gives him a cold in the head.

Concerning relationship to other departments. All departments combined make the road; if one falls behind the road suffers. Should we co-operate? The "ayes" have it.

Now for "Bill Brown." Bill's plans of telling the men what he expected of them is O. K. but, as he says, later, all men cannot be talked to alike. I believe that Bill should have interviewed his men separately instead of calling them together in this way; he would be able to get each man's views on his promotion and establish a personal relation with his men.

It is not always a good policy to explain changes in management, shut-downs, cuts or short hours to foremen but certainly a foreman should keep in touch with business and working conditions and should be interested in new methods of getting work out and to gain this end it is necessary that he read modern mechanical journals.

A foreman should be kindly in his contact with men, not only with new employees but with all employees. He should, however, be strictly impartial. Instead of personally making the new man "at home," I think he should permit him to work with an old employee for a day or two, exercising care in the selection of the employee so that the proper shop spirit may be instilled in the recruit.

Improved machinery or new inventions should be studied so that they may be understood when eventually installed, but undue haste in advocating a change when the old machine is not obsolete and can do the work reasonably fast would be a breach of trust, because it would involve the unnecessary expenditure of a sum which might be used to a greater advantage somewhere else.

Knowing and bringing home to the workman a realization of the cost of material is a subject in favor of which too much cannot be said. It is an absolute misfortune that competitive methods prohibit the manufacturing companies publishing prices of machines and materials in the advertisements in various trade journals. If a railroad company published a list showing the price paid manufacturers for materials the cost of printing it would be saved in 3/8 in. nuts alone.

All material having any salvage value should be saved carefully; only sufficient material to cover the job should be drawn from the storekeeper. Material should be used and conserved as carefully as a good mechanic uses and cares for his tools.

The day of the bullying foreman and the foreman who takes an improper advantage of his position has passed. This is the day of the foreman who has proven his worth as a leader.

President W. J. Harahan, of the Chesapeake & Ohio, has authorized the purchase, at a cost of about $8,000,000, of the following equipment: 20 simple Mallet type locomotives; 75 Mikado, heavy type locomotives; 5 heavy Pacific type locomotives; 10 heavy type switch engines; 125 steel caboose cars; 10 all-steel combination passenger and baggage cars; 3 all-steel mail cars; 2 ditchers; 4 dump cars and 2 locomotive cranes. The company is now in the market for this equipment.

The foreman and his responsibility*

The "big boss" drops in on an imaginary staff meeting—Pertinent suggestions on discipline and conservation

By W. J. Taylor

General foreman, Southern Pacific Company Shops, Sparks, Nev.

WEBSTER'S definition of opportunity is: "Suitable time, combined with other favorable circumstances." One favorable circumstance must be that we shall be fitted by training, study and experience to accept the responsibility imposed upon a foreman.

The opportunities of a foreman in railroad work are unlimited. A glance at those who have succeeded and are holding high executive offices, demonstrates that those who have worked hardest, have been honest with themselves and employers and are morally and courageously firm and just are the ones who have succeeded. They have been able to concentrate their minds on each individual position as they have advanced, and their training and experience has enabled them to meet any emergency unruffled and with quick and able decision, given in a manner to command respect.

Opportunities sometimes seem slow in presenting themselves and many who are over ambitious become discouraged and lose heart at the very moment when promotion may have been within their grasp.

The foreman who cannot apply himself to his job with his whole heart, giving the best that is in him—even under adverse circumstances or criticism—will not succeed. The little demon jealousy must always be watched closely, as he can undermine and destroy the chances of an otherwise successful foreman.

It is a fact that many men have succeeded in securing advancement and recognition through their ability or gift of a good "flow of talk," but those men are generally lamentably weak in doing the real things that count. They usually maintain their precarious standing by informing their superiors that a suggestion or improvement made by Bill Jones was their own particular idea. We must, however, be thankful in knowing that there is now less chance of advancement for this class of man.

We must be experts in our particular line. Opportunity seldom presents itself to those who continually are compelled to say: "I do not know."

As for the so-called strategic position occupied by the foreman and his opportunity for strengthening the organization which he directs, or assists in directing, and making it function more efficiently, we should like to make the following observations:

An interesting staff meeting

Consider a railway terminal shop and roundhouse, with a total of fifty foremen in the motive power department and twenty in the car department. We will inaugurate a practice of holding semi-monthly meetings. The general foreman of each department takes charge of these meetings, which will be held separately for each department because of the widely varied topics which will come up for consideration. Such meetings to be held during regular working hours and to be attended by the heads of each department, and those assistants who can be spared. After the meeting has been opened, and the general foreman has spoken on such subjects as safety, production, co-operation, etc., suggestions are solicited. The results are really surprising.

Those comprising a supervisory staff in the majority of our railway organizations come from all sections of this country and from European countries. These discussions are therefore most instructive. Minutes of these meetings are taken and printed, and distributed to all foremen. Suggestions of merit are referred to the master mechanic, and perhaps higher.

The seventy foremen are especially skilled and intelligent; they were picked for supervisory duties because of this. They are directly responsible in disbursing perhaps $125,000.00 a month. (Some responsible task!) Might we suggest that the general manager of the railroad operating these shops scratched his head one day and said to his superintendent of motive power: "That is a lot of money to intrust to those men to spend each month.

"Let us go over and see if they are really capable." On arriving at the shops they are informed by the master mechanic that a foremen's meeting was being held and they accepted an invitation to attend.

After a few introductory remarks by the master mechanic, both the general manager and the superintendent of motive power make a few remarks and the meeting resumes open discussion. At the invitation of the general foreman the superintendent of motive power takes the chair. Bill Jones, machine shop foreman, gets up and wishes to respectfully draw the superintendent of motive power's attention to the fact that he is using an old wheel lathe, built in 1878, for turning tires on an engine that was purchased in 1924. Bill says he is wondering why the management did not think it necessary to keep up-to-date with its machinery as well as with its locomotives. Superintendent of motive power coughs, and says he will look into the matter.

Next, our roundhouse foreman gets up and states that he is using an old shop-made crane for loading coal into tenders that was made in 1900, and tells of another method with which he had loaded coal while working for the XYZ road. Many other matters are discussed and at the conclusion of the meeting the superintendent of motive power promises the foremen assembled that in the future he will keep his eye a little more closely focussed on them as he realizes they are back of him in producing at a minimum cost.

The foreman's responsibilities

The responsibilities of a well trained, honest, conscientious foreman are such that he should realize and appreciate at all times the trust that has been placed in him. He should have such intellectual and moral capacity as to be able to discriminate and choose between right and wrong. He is accountable to his employer in seeing that money expended under his supervision is wisely spent, that every man employed under him gives an honest day's

* One of the articles submitted in the *Railway Mechanical Engineer* competition on this subject. The first, second and third prize articles have appeared in the June, August and September issues, respectively. Interesting comments on the first prize article also appeared in the two latter issues—the famous "Bill Brown"—"Top Sergeant" controversy.

labor, that material is not wasted, that tools are carefully used and conserved; also that the morale of the organization, over which he supervises is kept up to the highest standard. Also that there is harmony and co-operation between supervisors, between supervisors and men, and between the men themselves. The attainment of proper co-operation between all units of an organization should be a responsibility that all foremen should accept and strive to achieve. Co-operation extending from the head of an organization, and embracing all members of the official family, with the foreman would no doubt tend to make the whole machine function more efficiently.

The pompous official does not sense his responsibility. The foreman and the highest official are (or should be) striving for the same results. In demanding an honest day's work a foreman must know his men, must know how the work should be performed and how much time should be consumed on each job. It is possible for a man to work hard for eight hours and accomplish nothing. Accuracy must be constantly encouraged to prevent the necessity of doing work over. Spoiling of work is generally the result of poor supervision, and added to the waste of money for time expended, the cost of material is usually doubled.

Efficiency cannot be maintained without discipline, but discipline in overdoses is like an overdose of food or medicine,—it makes one more sick. When censuring a man a foreman must be firm. Infractions of established rules must never be overlooked for one man and strict discipline be given another. Encourage your men,—a discouraged man is of little use.

Conservation of material

The conservation of material is a subject that deserves the closest study and the foreman who conserves "until it hurts" is one who surely senses his responsibility to his employer and recognition is sure to come his way. His responsibility should not direct that he should demand of the storekeeper that an enormous stock of material be kept on the shelves, but that no more material be kept on hand than is absolutely essential to the proper running of the plant without delays. By close observation he can anticipate his requirements far enough in advance to eliminate the necessity of large stocks being maintained. Patching and substituting are two practices which should be approached with caution.

The abuse and loss of tools of various kinds should demand the strictest attention. Tools issued and held in tool rooms, or given out to individuals, should be periodically checked and requisitions for materials should be carefully scrutinized by the responsible foreman, who should ask himself in each instance: "Is it absolutely necessary that this material or tool be issued?"

Here is an instance to illustrate how one foreman recognized his responsibility in conserving material: In a plant "once upon a time" it was the custom of the machinists to use white lead on boiler studs, etc., before screwing them into place. The pipe fitters used this same material on pipe fittings. The boilermakers and mechanics got the habit and it was no unusual sight to see little pots, possibly a pipe cap or pieces of paper with white lead on them scattered promiscously around the shop. Suddenly there was an order that no more white lead should be issued for this purpose. Result—saving of many dollars and the work went on just the same.

The average foreman has an intellect that is fertile, capable of development. With encouragement coupled with harmonious co-operation and recognition from his superiors, the foreman is generally eager to grasp the opportunity if it presents itself, and through this sense of responsibility will seldom fail to make good in any task imposed upon him.

Traveling Engineers hold successful convention

Report on mechanical stokers and paper on train control feature annual meeting at Chicago

THE Traveling Engineers' Association held its thirty-third annual convention at the Hotel Sherman, Chicago, September 15 to 18, inclusive. There were about 1,000 members and guests in attendance at the opening session. The report of the secretary showed that the association had 105 new members and 252 members reinstated during the past year, making a total membership at the present time of 1,593.

The opening address was made by W. J. Fee, road foreman of engines, Canadian National, Lindsay, Ont., and president of the association, whose remarks are abstracted below. The association was also addressed by C. G. Bowker, general manager of the Grand Trunk Western, Detroit, Mich., who called attention to the splendid opportunity which members of the Traveling Engineers' Association have of improving locomotive service on the railroads through papers presented at the annual conventions and subsequent discussion. Mr. Bowker said that while the traveling engineer's duties are many, they all are important. He must keep a close supervision upon the power assigned to his territory, riding the engines frequently and keeping in touch with their condition. He must instruct engineers in the proper method of handling engines and see to it that they keep water at the proper level in the boilers, especially on superheated locomotives. He must see that his engines are properly lubricated in order to prolong the life of the cylinder packing and obtain the greatest possible efficiency in operation. Mr. Bowker also emphasized particularly the opportunity of the traveling engineer to improve locomotive performance through the prevention of carelessness and inattention to duty responsible for engine failures and also to a large extent for excessive fuel consumption.

The opening address made by President W. J. Fee, road foreman of engines, Canadian National Railways, Lindsay, Ont., was in part as follows:

Address by President W. J. Fee

Efficiency in railroad work is a matter of education and experience, and is mostly obtained through association with each other and exchanging the views of each

other's experience. Give us the benefit of your experience, and we will keep our members in position to aid in bettering locomotive service on their various railroads. Our superiors will then be satisfied that it is to the interest of every railroad to send its traveling engineers to these conventions to keep them informed as to the latest developments in connection with locomotive equipment and operation.

No association can boast of a wider zone of usefulness, or a better record of achievement than this one. Transportation is the oldest and the newest problem confronting civilization. Transportation has been essential to human well-being and happiness, and has perhaps more accurately reflected human progress and achievement than any other industry, not excepting agriculture.

The locomotive being the prime factor in railway operation, the history of its development is a romance which has no parallel in the records of human achievement, nor can too much credit be given the men whose stupendous labors brought into practical form such devices as the air brake equipment, feed water heater, superheater, stoker, booster, power reverse gear, different valve gears and many of the numerous devices now applied to the present day modern locomotive.

Progress made in mechanical stokers

Up to June 1, 1924, 8,989 mechanical stokers had been applied to locomotives.

From information obtainable and from personal observation it should be possible for a mechanical stoker of the present-day type to operate approximately 90,000 miles on the locomotive before receiving a general overhauling; however, at the time the locomotive is receiving classified repairs the stoker should receive a thorough inspection and the necessary light repairs be made. It is presumed with reference to the above that the stoker and parts received proper lubrication and correct operation.

Maintenance costs 0.1 to 0.15 cents per locomotive mile

From information available, at sources where inquiries were made, as to actual differential covering cost and maintenance of past types of stokers over that of the present-day type, no figures were to be had; however, the standard type of stoker in operation today can be maintained for approximately 0.1 to 0.15 cents per locomotive mile.

This includes the cost of all stoker parts used at overhauling; however, minus cost of labor.

Due consideration should be given to the construction of locomotive tenders to provide fuel supply for the use of the fireman who either through lack of knowledge in the operation of the stoker or because of a clog occurring may be required to revert to hand firing. As a rule in case of stoker trouble a fireman will make added efforts to hand fire the locomotive if fuel is available without restriction. This will also increase the tendency of firemen to give proper consideration to the use of the scoop during standby and other delays, at which time the temperature of the fire-bed may become low, and if without forethought extreme care is not taken banks may form over the fire-bed through the use of the stoker.

On territory where the application of mechanical stokers is being considered it is important to establish the practice of removing all foreign and non-combustible material at fuel stations and coal mines. Delays will be eliminated by establishing this practice and continuity of operation assured to stokers, thus preventing interruption of service at critical periods of operation during sustained efforts on the part of the locomotive.

The inclination of individuals to study and qualify for promotion has through the application of the stoker shown itself on the increase. The present progressive examination is of such a nature that earnest study must be applied for an individual to qualify from the position of fireman to that of a locomotive engineer.

Influence of stoker on detection of packing blows

Valve and cylinder packing blows should be observed with extreme care. Engine crews should be instructed in the art of testing for them. As the mechanical stoker can and will deliver the required fuel before the weakening of the locomotive due to loss of power is discernible, certain engine crews are not entirely familiar with the proper method of discerning and testing for valve and cylinder packing blows, especially so in the case of superheated locomotives.

Special attention should be given to replacement of stoker parts, as well as maintaining the openings in the firing nozzles, distributing arrangement and true alignment of such parts by the roundhouse forces.

Operation of stokers on inbound or terminal tracks, prior to the arrival or after leaving of crews, except by inspectors, should not be permissible. It is important that fire-beds be built up at terminal points and delivered to the crews in a light and level condition and free from clinkers. Prior to leaving the outbound track the whole stoker should receive close observation of the engine crew, in order to know that it is in serviceable condition and that

the flow of fuel is available. Fire-beds should be built up by hand-firing and a proper degree of heat obtained. The thickness of the fire-bed is to be in proportion to the degree the locomotive will be worked and according to characteristics of the fuel used. Engineers should gradually work their locomotives up to the maximum working capacity needed, rather than in a sudden manner, allowing the firemen to bring the fire up to the proper degree of heat, depth and division of fuel over the grate area as a whole, so that forcing of the fire may not be required. This will insure getting the fire-bed at what we term a light, bright and level condition, which is necessary for securing the most economical results in consuming the volatile gases of the fuel with resultant barometer of efficiency—a clean stack.

Modern stokers promote reliable operation

The schedule of the time table makers and tentatively expected performance of the extra as well as the regular trains by the dispatcher is based upon the even, steady and continuously normal performance of the locomotive. By no other presumption can the plans of the dispatcher become definite. Dispatchers must have certain confidence in locomotives as well as in engine crews to perform certain tasks. These tasks, regardless of weather conditions, the modern locomotives will do, even though called upon to develop in comparatively short time rates of horsepower from zero to a total maximum effort. With the mechanical stoker, dispatchers feel assured that they have a locomotive with which there is no doubt of failure resulting from the physical effort on the part of the fireman in being unable to maintain constant pressure under sustained effort.

The report was signed by D. I. Bergin, chairman, road foreman of engines, Wabash; J. P. Britton, road foreman of engines, B. & O.; J. H. De Salis, master mechanic, N. Y. C.; M. A. Daly, fuel supervisor, N. P.; and Henry H. Wilson, general road foreman, B. & O.

Discussion

In discussing the committee report on mechanical stokers, various members emphasized the points brought out in the report that the modern stoker of improved design is practically foolproof in operation, low in maintenance cost with reasonable care and attention to lubrication, and decreases railroad operating costs. Practically without exception, comments on the report were favorable. Decreased operating cost is accomplished because the stoker makes possible an increased tonnage rating of locomotives, prevents many train delays due to man-failures in firing and under certain conditions saves fuel over the older method of hand firing. In addition, the advantage of the mechanical stoker as a safety device was emphasized in that it enables the fireman to keep a closer watch for roadway signals which may be missed, particularly if he has just put in a fire and is partially blinded by the intense glare from the firebox. In commenting on maintenance, one of the members said that the stoker engines on a series of locomotives built in 1913 have never yet been taken from under the locomotives, all repairs having been made at outlying points with the stoker engines still in place.

Continuous train control with cab signals

By E. Von Bergen
General air brake and lubricating engineer, Illinois Central, Chicago

At this time last year there were but four installations of train control that could be termed service installations, the remainder being test installations. Of the four, three were of the intermittent contact type, viz., the Miller on the C. & E. I., the Regan on the C. R. I. & P., and the American on the C. & O., and one of the continuous induction type, viz., the Union on the Pennsylvania. Since that time practically all of the remaining 45 roads embraced in the first order issued by the Interstate Commerce Commission have contracted with manufacturers for their respective installations, quite a number having a division in operation.

Contact type rendered obsolete

As none of these roads have selected a contact type of device, but have all chosen induction types, either of the intermittent or continuous type, it is apparent that railroad operating officers who have studied the problem are practically unanimously of the opinion that the development of the induction types has rendered the contact types obsolete. The objections which have for years been set forth against contact types, viz., clearance problems, shock resulting when locomotive apparatus comes in contact with wayside, interference of ramps with snow plows, etc., were overcome with the development of the induction types, and once it was proved conclusively that the wayside indication could be transferred aboard the locomotive positively and reliably without any contact between locomotive and wayside apparatus, and this at approximately

the same cost, the death knell of the contact types was sounded.

Intermittent vs. continuous

Although an intermittent type of device meets the requirements of the I. C. C. and generally speaking the first cost of any division installation of the continuous type is substantially greater than that of the intermittent, there is little benefit to be derived from an intermittent device unless speed control is incorporated, and the disadvantages of speed control will be discussed later.

With an intermittent automatic stop, all that can be expected is that the device will apply the brakes and stop the train in the event the engineman fails to stop for a stop signal, or to take proper action recognizing same. From a practical viewpoint, it is apparent that if two or three hundred thousand dollars must be expended for an automatic stop, it is good business to spend 30 per cent or even 50 per cent more, if funds are available to purchase a continuous stop device which will not only provide all that is provided by the intermittent device, but will in addition provide a continuous light signal in the cab keeping the engineman advised at all times of the condition of the track ahead. This device will also apply the brake at any point in a block when conditions ahead change from "clear" to "danger" instead of performing this function only when passing a fixed point at the entrance to a block. Conversely while a train is traversing a "red" block, and conditions ahead change to "clear" the condition is immediately reflected on the locomotive, and the engineman is free to proceed at full speed. This will very often facilitate operation, whereas with an intermittent device the train under these conditions would be restricted throughout the block to that speed imposed by the indication at the entrance to the block.

Another substantial advantage provided by the continuous cab signal is that with its use the present rule requiring a train to stop at a "stop and proceed" automatic block signal becomes entirely unnecessary. The cab signal should show but two indications, viz., either green or red. As one of these indications is constantly confronting the engineman in the cab, the present rule should be changed to read: "A green cab signal indicates track ahead is clear and authorizes maximum speed. When cab signal changes to red, the speed of the train must immediately be reduced to that at which train can be stopped within distance track is seen to be clear."

It is essential that an audible cab signal, preferably an air whistle, be provided to sound when cab light signal changes from green to red, to attract the engineman's attention, should he be looking away when the change occurs.

Forestalling feature

The forestalling feature is a device incorporated in an automatic stop, so arranged that when operated by the engineman within a given period before and after the train control apparatus on the locomotive receives a stop indication from the wayside, a brake application is prevented, and the engineman is free to control his train and manipulate the brakes as his judgment dictates. If he fails to operate the forestalling device within the time allotted, the brakes will be applied and the train brought to a stop regardless of any action he takes. When Order 13413 was first issued by the Commission, the forestalling feature was prohibited. This made the installation of an automatic stop on nearly all large roads entirely out of the question, as a train would be brought to a stop every time a stop indication was encountered, regardless of the action of the engineman, and in numerous cases would have imposed two stops where one is now required. It would also have required doubling of hills by many heavy freight trains on roads where automatic block signals with tonnage signals are employed. This would have produced an intolerable operating condition, and many roads were thus forced to select devices embracing speed control at a vastly increased cost and involving complicated mechanism difficult to maintain. In its decision handed down in July, 1924, covering the hearing on the second Order 13413, the Commission modified its first order to the extent of allowing the use of the forestalling feature, but reserving the right to withdraw this permission at a future date if found necessary. This has been the means of saving large sums of money that would have been expended for speed control apparatus. The theory on which the forestalling feature had been objected to was that an engineman might forestall a brake application and run into collision with another train in a manner similar to cases which have occurred when automatic block signals were disregarded; but an automatic stop has been in service for more than ten years on one road and no accident has ever occurred that could be attributed to the use of the forestalling feature. It may be said that possibly no accidents would have occurred on that division if no automatic stop or train control had been employed, and there is, of course, theoretical basis for argument that a collision might occur through the abuse of the forestalling feature by an engineman, but it is difficult for us as practical men with years of locomotive experience to conceive that with a continuous cab signal an engineman would deliberately disregard a red light staring him in the face in the cab and proceed to collide with another train.

Speed control vs. automatic stop

Any train control apparatus on locomotives requires a high degree of maintenance, but with speed control added, this is increased. The experience of the writer has shown that of the maintenance troubles arising, a large proportion (probably 50 per cent) develop in the speed control mechanism. It has been shown that with properly trained men and intensive supervision, the stop apparatus, both electrical and pneumatic, can be maintained in good working order, but even with the highest degree of maintenance many troubles occur in the speed control apparatus, causing undesired stops and cutting out of the device en route. Numerous tests have developed that the lowest speed at which it is practical to establish the functioning of the speed control apparatus on long freight trains is 20 miles an hour; in other words, if it is set to impose a lower speed restriction it will apply the brakes when this speed is exceeded, and although intended to release the brakes and allow the train to proceed immediately the speed is reduced below the restriction, it does not so work out in practice and the train is brought to a stop. This also frequently occurs when the speed is set at 20 miles an hour. Analysis of all the collisions which occurred on one large railroad for 10 years past developed there was not one instance where an engineman had passed a stop signal and was aware he had passed it that the speed of the train at the time of the collision was greater than 15 miles an hour. With such a record it would be folly to expend the large sum required for the purchase of speed control apparatus, as well as to incur the heavy maintenance cost of and troubles involved in an apparatus which can only be expected to limit the speed of train to that which is substantially higher than those at which collisions occur under conditions which it is presumed to prevent.

Speed control is a beautiful theory, and many theoretical arguments can be advanced by technical men to prove its necessity, but when its functions are analyzed on a practical basis, it is difficult to justify its existence, except possibly in cases where unusually dense traffic prevails

and it is necessary to operate many fast trains on very close headway.

Elimination of wayside signals

With a continuous induction system, incorporating visual cab signals, there appears no good reason why wayside block signals cannot be dispensed with. Practically the only objection to this procedure is that in the event of failure of the electrical apparatus on the locomotive the engineman would be left without any indication whatever of track conditions ahead. The answer to this is that there are thousands of miles of track being operated safely and efficiently today without wayside signals of any kind, and with the remarkable development of continuous induction types of automatic train control during the past few years we have a right to expect them to function as reliably as automatic block signals. Even if more failures of this apparatus occur than with automatic block signals, an occasional train can surely be depended on to safely traverse a portion of a division without the aid of signal protection.

Split reduction vs. continuous reduction

Volumes have been written on the air brake action when the brake pipe reduction is brought about by the train control apparatus. On account of recommended practice covering manual manipulation of the brake valve requiring the application of the brakes to be made with a split reduction, chiefly to allow slack in long trains to bunch before the full application is accomplished, many air brake experts insist that the train control apparatus apply the brakes with a split reduction also. One of the most prominent train control manufacturers urgently recommends this feature. The incorporation of a split reduction feature further complicates an already complicated device. The Illinois Central made braking tests on heavy freight trains ranging in length from 63 to 102 cars at speeds of 8 to 38 miles an hour, and on ascending and descending grades. Tests 1 to 14 inclusive were made with continuous reductions, the brake pipe venting until the train came to a stop, which is the method usually employed with an automatic stop. Tests 15 to 29 inclusive were made with a 7-lb. initial reduction, followed in five seconds with a 17-lb. reduction, which is the method employed by one of the leading train control systems embracing speed control. It is extremely interesting to note that in none of these tests was a stop attended with a shock that could be termed severe.

The writer has also witnessed many other tests, with both split and continuous reductions with train control during the past three years, on ascending and descending grades, throttle open and throttle closed, and in no case did any damage result from a continuous reduction. In tests where the throttle was closed and the brake pipe reduction started at the same instant on freight trains of 100 or more cars at speeds of 10 miles an hour or less, slack ran in at the rear end with a severe shock with either a split or a continuous reduction. When the brakes were applied at any speed and the throttle held open to stop, the slack action was in no case severe.

In the light of these tests, and in view of the fact that with an automatic stop incorporating a forestalling feature, the brakes will very seldom be applied by the automatic train control apparatus. The additional expense and complications involved by the split reduction apparatus are not warranted. Where speed control is employed, the split reduction may possibly at times fulfill a useful purpose, as unexpected brake applications will be received more or less frequently.

Conclusions

When financial conditions permit the installation of the most desirable device, an automatic stop of the continuous induction type incorporating the following features is recommended:

1—Continuous visual cab signals.

2—An audible cab signal to attract the attention of the engineman to a change of indication from clear to danger.

3—So designed that the engineman, if alert, may forestall a brake application within a stipulated period of time.

4—Engineman to have an interval of approximately 10 seconds before to 10 seconds after the cab signal changes to "danger" in which to operate the forestalling feature.

5—If the engineman fails to operate the forestalling feature, a brake application will result and continue until the train is brought to a stop.

6—Brake pipe reduction to be at the same rate as a manual service, but to continue until train has come to a stop.

7—Apparatus to consist of the smallest possible number of parts to provide these functions and meet the requisites of the I. C. C.

As the modification of the first order by the Commission, following the use of the forestalling feature, means the saving of vast sums of money in installation and maintenance costs for the railroads compelled to install train control, and selecting automatic stops, and also provides for the least possible interference with the engineman in operating the locomotive in his charge, the members of this assoication can lend invaluable assistance by impressing as forcibly as possible upon the enginemen under their jurisdiction the extreme importance of using the forestalling feature only when they are certain no hazard is involved. If enginemen should make use of this invaluable feature indiscriminately or carelessly and this practice result in a serious collision, it is not unlikely that the Commission would withdraw the permission granting its use, which would force the application of speed control with its complications, troubles and excessive cost.

Discussion

A representative of the Michigan Central stated that this road has abandoned its 20-mile test installation of the continuous train control and is proceeding to install two divisions of the intermittent inductive train stop. He therefore wished to defend the decision of his road in such choice against the argument presented by Mr. Von Bergen. He said that the intermittent inductive type is simple, requires a minimum amount of change in the wayside signaling and meets the requirements of the Commission. He considers the wayside signals absolutely necessary and believes that the majority of locomotive enginemen are not in favor of eliminating wayside signals.

J. B. Stewart (M. P.) reported that the Missouri Pacific has a complete engine division in operation under train control of the intermittent inductive type which is operating with entire satisfaction. He therefore wished to take issue with Mr. Von Bergen as to any concerted approval of the continuous or any other type at this time Mr. Stewart explained that at certain locations on curves or on bridges speed restrictions are enforced by speed magnets which operate the train control to stop the train in case the speed is over 25 miles an hour.

E. Wanamaker (C. R. I. & P.) stated that the Chicago, Rock Island & Pacific has been operating a complete engine division under train control protection of the intermittent ramp type with speed control for the past 18 months and that results have been satisfactory in spite of severe winter weather.

L. F. Howard (Union Switch & Signal Company) stated that his company is prepared to furnish apparatus to give either the split reduction or the continuous reduction, whichever the railroad desires. On double track there may be the liability of accidents caused to other trains due to buckling of train where continuous reduction is used that might be eliminated by the split reduction. In explaining the desirability for speed control Mr.

Howard said that braking distance can be fixed only when speed is considered and that the function of speed control is to limit the speed on approaching the brake application point such that the train will be stopped in a fixed distance. It was also his contention that speed control is quite desirable in occupied blocks. In Mr. Howard's opinion the cab signal can be developed to be as reliable as the wayside signal. However, this function will depend on future developments.

C. A. Lyons (Regan Safety Devices Company) brought out that there are certain places such as in yard limits on bridges and in tunnels where train stops are undesirable and that such stops may occur with the continuous system but not with the intermittent system because the braking points are fixed in the latter system. He explained that with speed control the train can be continued in motion at a definite speed, thus facilitating movements and eliminating stops. Mr. Lyons answered one objection to the ramp by stating that notches can be cut in the aprons of spreaders, snow plows, etc., to clear the wayside ramps satisfactorily. If proper sized exhaust ports are provided Mr. Lyons stated that in his opinion continuous reduction will give satisfactory air brake operation on almost any road.

E. Von Bergen (I. C.) in closing the discussion on his paper, answered several of the points brought up. He agreed with the Michigan Central representative that wayside signals should not be eliminated if the intermittent train stop system is used. However, in his opinion many enginemen will prefer a cab signal to wayside signals if given their choice after experience with both. In reply to Mr. Lyons he said that in his opinion if conditions are such that the train should be stopped, the quicker it is stopped the better, regardless of the location and without waiting until a designated point is reached.

Results of improper handling of locomotive and air brakes

Assuming that good judgment and sound principles have been considered in making rules and laws governing the building as well as operation of brakes on trains, the first thing to consider is the maintenance of this equipment so that it will respond when desired according to laws and rules that were made to work with the builder, as well as to the operator's ideas and instructions.

If this is done, the next thing to consider is the good judgment of the engineer in the operation of the locomotive and brakes to avoid violent slack action in applying or releasing the brakes when slowing or stopping a train.

It is the opinion of the committee that with long freight trains many draw-bars and draft riggings are damaged and severe shocks in slack action (damaging the lading) result from closing the throttle abruptly applying the brakes on the engine at the same time as on the train before the slack has had time to adjust or bunch, and releasing the brakes while the train is in motion with the head end moving faster than the rear.

In connection with piston travel the commitete calls your attention to Table I, which shows the difference in cylinder pressure and effective braking power with piston travel of various lengths, as compared with that of eight-inch travel. Table II shows the equalization pressure in brake cylinders from four to twelve-inch travel with the respective brake pipe reductions.

The fundamental enemies of the modern air brake are uneven piston travel and leaks. Uneven piston travel causes a variation in every operation of the air brake system.

Table I gives the results of test made to show what is done in a service application with a ten-pound reduction of brake pipe pressure. As a matter of fact, the results actually obtained in service will be from two to three pounds lower than shown in the table on account of leakage, etc. (When the above tests were run there was no leakage and everything was air tight.) The effective braking power is that which would be delivered to the brake shoes for the cylinder pressure given. Assuming that the leverage is designed for 60 per cent braking power at 50 lb. pressure, this percentage being now recommended in freight service for steel cars or wooden cars with steel underframe. In practice eight-inch piston travel is usually taken as standard for freight service.

Table I

Piston travel	Cylinder pressure lb.	Effective braking power Per cent	Comparison with 8-in. travel Per cent	
4-in.	52½	63	130	greater
5-in.	41	49	78	greater
6-in.	34½	39	44	greater
7-in.	27½	33	20	greater
8 in.	23	27½		
9-in.	19	23	16⅓	less
10-in.	16	19	31	less
11-in.	13	15½	44	less
12-in.	11	13	53	less

The proper piston travel is that which will develop approximately 50 lb. cylinder pressure when the auxiliary

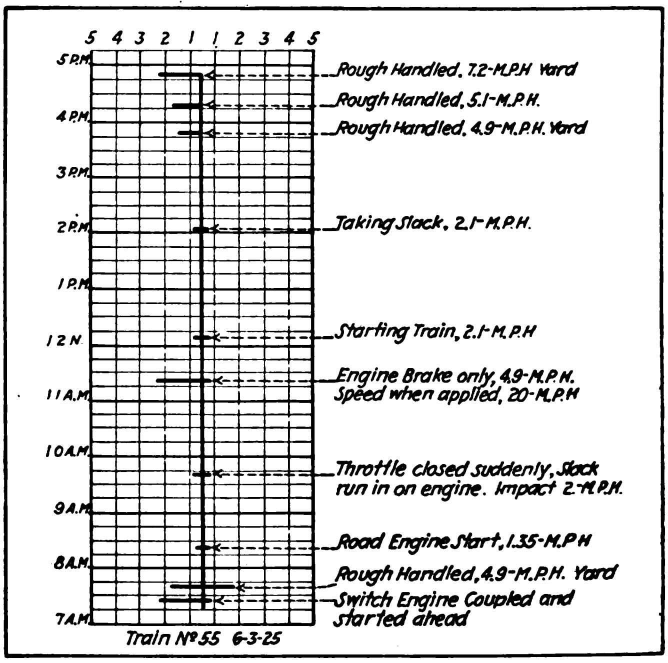

Fig. 1—Record of impact machine with 62-car train

and brake cylinder pressures become equalized from an initial brake pipe and auxiliary reservoir pressure of 70 lb. when a 20-lb. brake pipe reduction is made. This 50-lb cylinder pressure will then be the limit of a full service application, and should be obtained simultaneously on all cars. Table II shows approximately the pressure at which the cylinder and auxiliary reservoir above mentioned will become equalized for different piston travels, and the brake pipe reductions required to give this equalization.

Table II

Piston travel	Equalization pressure	Brake pipe reduction
4-in.	59 lb.	11 lb.
5-in.	57 lb.	13 lb.
6-in.	55 lb.	15 lb.
7-in.	55 lb.	16½ lb.
8-in.	51½ lb.	18½ lb.
9-in.	50 lb.	20 lb.
10-in.	49 lb.	21½ lb.
11-in.	47 lb.	23 lb.
12-in.	46 lb.	24 lb.

Particular attention should be given in this table to the large variation in brake pipe reduction, the short piston

travel requiring a smaller reduction and equalizing at a higher pressure than in the case of longer travel.

In proof of the committee's contention that 85 per cent of rough handling is done in yards, we call your attention to Fig. 1, which is a chart taken from a 62-car train. The impact machine was placed in the tenth car from the engine and it shows that 2.1 miles per hour was the greatest impact on the line of road, except that at 11:30 a.m. the engine brakes were used purposely to see just what the impact would be with a speed of twenty miles per hour and the slack gently bunched. Even with this light handling of the independent brake valve, the impact was 4.9 miles per hour, while the machine showed that the car was rough handled in both terminals.

In conclusion the committee wishes to call your attention to the freight claim expenditures (for 1924 on 95 per cent of U. S. and 65 per cent of Canadian mileage):

Damage due to rough handling	$9,584,984.00
Unlocated damage	8,273,312.00
Concealed damage	2,148,475.00
Freight train car repairs (1923 report for Class I Roads, U. S.)	153,509,170.00
A total of	$173,515,914.00

The report was signed by James Fahey, chairman, traveling engineer, N. C. & St. L.; N. Suhrie, road foreman of engines, Penna.; R. Hammond, road foreman of engines, N. Y., N. H. & H.; C. H. Dillinger, air brake supervisor, N. Y. C.; and H. W. Sefton, supervisor locomotive and fuel performance, C. C. C. & St. L.

Discussion

At the close of the reading of this report an extended discussion took place. One member questioned the need of automatic slack adjusters since if the piston travel is correct when a train leaves the terminal it will be the same at the end of the run save for a small fraction of an inch additional slack due to brake shoe wear. It was pointed out that after the first brake application the engineer feels the slack action of the train and must govern himself accordingly in future brake applications. In the main, the contention of the committee that most desirable brake action is secured when the slack is kept stretched and the brakes applied before the throttle is closed was upheld. H. H. Burns, Westinghouse Air Brake Company, agreed with a previous speaker in questioning the advisability of placing as much emphasis on piston travel as was done in the committee's report. While insisting that a constant effort should be made to improve the standard of air brake maintenance including recommended piston travel, Mr. Burns said that the improvement within the past year or two has been such that irregularities in brake action due to non-uniform piston travel are far less serious than those occasioned by the combination of loaded and empty cars in the same train with disproportionate braking power. Moreover, the drop in pressure at the end of a 100-car freight train, which may be as much as 15 lb., will occasion a greater variation in braking power between the front and rear cars of the train than would be caused by considerably more than the usual variation in piston travel.

Mr. Burns also commented strongly on the damage (often concealed) done by trying to spot locomotives for coal or water without uncoupling from heavy drag freights. He pointed out that while road foremen and sometimes two or three of their men may be able to do this successfully, by far the great majority of enginemen cannot spot a heavy tonnage train at a water standpipe or coaling station without unnecessary rough handling. The general conclusion was that no hard and fast rules can be adopted regarding this matter, which must be left more or less to the judgment of the engineman, depending on conditions. At the conclusion of the discussion the Association voted to adhere as closely as possible to the general rules laid down by the air brake companies for brake operation and in addition make brake applications with the slack stretched as recommended by the committee.

Appliances for lubricating locomotives

Until recently the hydrostatic lubricator of various designs had been the only medium used for applying oil, but with the advent of larger locomotives it has been felt that a device should be produced which would fulfill these functions more efficiently. With this end in view, the mechanical or force feed lubricators of various designs have been placed on the market, and have been applied to a considerable extent. Your committee has sent out a questionnaire to the membership with a view of securing information as to the degree of success secured from the application of the force feed lubricators; also, how their operation compares with the hydrostatic lubricators. The replies received would indicate that while a great number of those lubricators have been applied, they have not been in service long enough to secure definite data as to their efficiency as compared with the hydrostatic lubricators.

Each of the two types of lubricators has its separate merits and defects. For instance, by applying the hydrostatic lubricators to the large modern engines, it has been felt by some that because of the great length of the oil delivery pipes serious difficulties were being introduced in delivering the oil successfully to the valves and cylinders.

Not being able to secure any definite data comparing the hydrostatic and mechanical lubricators, the chairman of this committee will give his personal observation. We have applied mechanical force feed lubricators to our mountain type locomotives operating in heavy fast passenger service and have secured very satisfactory results. Certain defects were encountered, but with the experience we have gained these are readily overcome. The chief defect was choke valves leaking, which allowed steam to back up in the oil pipes and condense in the oil chamber. This condensation settled to the bottom and in some cases was of such a volume as to float the oil above the intake of the pump. This defect can be easily detected and remedied by the simple practice of opening the drain valve at the bottom of the lubricator and if water appears, this is an indication that a leaky choke valve exists and requires attention. Our staff has now been instructed and trained to watch this feature. The result is that this defect has now been practically eliminated. There are also instances where the lubricator apparently did not feed on one side. The cause of this was found to be choke fittings corroded and seized.

Some authorities claim that a lubricator should feed an amount of oil corresponding to the speed of the locomotive. This is not good reasoning, because the volume of oil required for lubrication is not always in proportion to the velocity, or to the area rubbed over. Especially is this so when the temperature of the rubbing surfaces is increased by some other agent than friction, which greatly reduces the viscosity of the lubricant and destroys the oil film in a very short time.

On this account the volume of cylinder lubrication would be regulated more by the cylinder temperature than by the area rubbed over. Assuming, then, that on account of occasional high water or bad water the oil film on the cylinder walls has been destroyed, how is this lubricating film to be restored if the volume of lubricant cannot be immediately increased? I might say that this film can be restored with the mechanical lubricator by lengthening the

cut-off, which generally would come in line when a condition of this kind arises. With a hydrostatic lubricator it would be necessary for the locomotive engineer to readjust the feeds.

The oil film is also often destroyed by the admission of front end gases to the cylinders when they are at high temperatures, and it must again be built up by the admission of a little excess oil, because the regular feed only supplies the necessary amount to replace the regular wear of the film, and cannot be expected to build up a new film. The lubricator must be equipped so its capacity can readily and quickly be adjusted to meet requirements.

Among the replies received to the questionnaire sent out was one from the London Midland and Scottish Railway, stating that this railway has 513 locomotives equipped with mechanical lubricators. They have no locomotives equipped with either the two-feed or the four-feed lubricators for oiling valves and cylinders, but a large number of their engines are fitted with eight-feed mechanical lubricators, and they also have three-cylinder compound passenger engines fitted with twelve-feed mechanical lubricators. In regard to the type used, they state that the mechanical lubricator used is of their own design, each oil supply being fed by its own pump unit. Regarding tests conducted between mechanical force feed and hydrostatic lubricators, they state that they have fitted some engines with hydrostatic lubricators, but prefer the mechanical lubricator.

One road uses graphite lubrication

The talk on lubrication of valves and cylinders so far has had to do with valve oil and of different methods of supplying it to valves and cylinders, but at least one large system has secured some very good results from the use of dry graphite for lubricating valves and cylinders. This graphite is prepared in the form of solidified cakes and is fed by what is known as a pendulum graphite lubricator. The magazine containing the graphite is situated on top of the boiler and back of the smoke-stack. The natural side motion of the locomotive while running causes the pendulum to swing over the cakes of graphite and dusts or scrapes off a small amount of graphite at each swing. The graphite scraped off passes through a pipe into the superheater header and extends to the valves and cylinders.

While the dry method of lubricating valves and cylinders has not been brought into use to any considerable extent, it is nevertheless the opinion of the committee that it offers certain advantages, and we would strongly recommend that this feature of lubrication of valves and cylinders be gone into as thoroughly as possible.

The report was signed by A. N. Boyd, chairman, road foreman of engines, C. N.; W. E. O'Brien, road foreman of engines, B. R. & P.; C. H. Holdredge, district road foreman of engines, S. P.; J. W. Wells, road foreman of engines, N. Y. C. & St. L.; and G. C. Jones, division road foreman, A C. L.

Discussion

The discussion of this report indicated that mechanical lubricators are now being used in considerable numbers on many of the roads and are giving good results. One of the members expressed the sentiment that most of the minor defects common to earlier types of mechanical lubricators have now been remedied and the installation of this device will solve many present lubrication difficulties. On long runs over two or more divisions there is no possibility of the first crew using more than its share of the oil in the lubricator as a certain fixed amount is fed to the valves and cylinders for every revolution of the driving wheels. The lubricator feed is set at the time of shopping the engine and cannot be changed without the authority of the road foreman or master mechanic. It is outside of the control of the engineman except in case of emergency when, to make necessary adjustments, he must break a seal.

A representative of the B. & O. said that mechanical lubricators require little maintenance except the pipes which are subject to breakage by vibration unless the lubricators are properly located with regard to this limitation. Experience seems to indicate that the back valve head is the best place. Discussion at the convention brought out the fact that mechanical lubricants can be used for delivering oil to practically any part of the locomotive, several roads using the various feed lines to air compressor, feed water pump and to the guides. In general, the advisability of a mechanical feed to the air compressor was questioned because the compressor is usually working hardest when the locomotive is still and no oil being delivered. It was testified that to meet this condition at least one of the mechanical lubricators has provision for feeding by hand, there being the objection, however, that operation of the hand wheel forces oil to all the feeds.

The possibility and advisability of setting the lubricator feeds to give ample oil while breaking in a new locomotive was emphasized, the feed later being reduced by proper authority as conditions make it permissible. E. Von Bergen, Illinois Central, said that general experience fails to show whether it is best to lubricate locomotives through the valves or the cylinders, good results have been obtained both ways. He personally believes that a majority of the oil should be delivered to the cylinders, and the Illinois Central practice is to supply 25 per cent to the valves and 75 per cent to the cylinders. Some of the members testified just the reverse, that they delivered 75 per cent to the valves and 25 per cent to the cylinders. One of the members commented on another advantage of the mechanical lubricator in that it permits locomotives to be hauled dead without taking down the rods and blocking the crossheads.

Election of officers and other business

At the concluding session of convention, the following officers were elected for the year 1926: President, J. N. Clark, Southern Pacific; first vice-president, J. B. Hurley, general road foreman of engines and fuel supervisor, Wabash; second vice-president, J. D. Heyburn, master mechanic, St. Louis-San Francisco; third vice-president, James Fahey, traveling engineer, Nashville, Chattanooga & St. Louis; fourth vice-president, Ralph Hammond, traveling engineer, New York, New Haven & Hartford; fifth vice-president, A. N. Boyd, traveling engineer, Canadian National. David Meadows, Michigan Central, was re-elected treasurer of the association. W. O. Thompson, New York Central, is life secretary.

The by-laws of the association were amended to provide for an increase in size of the executive committee from 12 to 18 members, the following new members being elected: J. N. Nicholson, fuel engineer, Atchison, Topeka & Santa Fe; D. R. Sweeney, traveling engineer, Chicago, Burlington & Quincy; A. White, general road foreman of engines, Southern; M. A. Daly, general fuel supervisor, Northern Pacific; W. L. Robinson, superintendent of fuel and locomotive performance, Baltimore & Ohio; J. E. Bjorkholm, assistant superintendent of motive power, Chicago, Milwaukee & St. Paul, and D. I. Bergin, road foreman of engines, Wabash.

As a Means of stopping leaks that develop in containers in transit, the Freight Claim division of the American Railway Association suggests the use of soap. It has been found that soap has been used successfully in garages to stop gasoline leaks, for it does not dissolve in gasoline or heavier oils, melts very slowly in water, and resists some acids.

An effective letter filing system

Method of filing correspondence numerically by classification—Letters located quickly whether referred to in reply or not

By Beno Farenwald

Night enginehouse foreman, Chicago, Milwaukee & St. Paul, Avery, Idaho

THE correspondence filing system described in this article has been used for two years in the office of the master mechanic of the Chicago, Milwaukee & St. Paul at Deer Lodge, Mont., having there demonstrated both its simplicity and effectiveness. The system consists of a classification of correspondence in such a way that each figure in the file number represents a name or classification.

In developing this system it is necessary to have a fairly definite idea of the nature of the correspondence handled and then pick out the most important differences in the correspondence and number them from 1 to 9. In like manner make a second division to represent the second digit and continue until you have enough digits and separations to suit the needs. It is not necessary to assign completely each figure of the classification at first; in fact it is best to assign only figures as there is immediate need for them.

Suppose it is desired to build up a filing system for a railroad mechanical office, with steam and electrical power and all other special equipment under one jurisdiction: The first step is to separate the major differences in the correspondence, possibly numbering steam locomotives (1), electric locomotives (2), gas electric equipment (3), special equipment such as steam shovels, ditchers, etc., (4), power plants (5), roundhouses (6), heavy repair shops (7), labor (8), general, or anything which cannot be classed under any of the above heads (9). The foregoing separations will then represent the first figure in the proposed file number, and in like manner, a second separation can be made as follows: Material (1), machinery (2), lubrication (3), coal (4), fuel oil (5), electric power (6), additions and betterments (7), wrecks (8), general (9). Then for the third set of figures, subdivide into: Reports (1); investigations (2), instructions (3), agreements (4), permits (5), federal laws (6), accidents (7), train delays (8), general (9). The fourth separation might be: Timekeeping (1), pay checks (2), accounting (3), enginemen (4), shopmen (5), other employees (6), discharged employees (7), general (8), unassigned figure (9).

In filing letters the key to the correspondence files would be grouped as shown in Table I, so that a file number can be given each letter quickly, after it has been read by the chief clerk or file clerk.

In addition to the classification in Table I another division which will classify more specifically is the use of a letter on the end of each file, corresponding to the first letter of the most important factor of the letter.

Suppose we now want to file some correspondence in reference to a compressor of an electric locomotive. This would resolve itself into 2298-C. In like manner a letter in reference to a labor agreement would be filed 8948-A. Correspondence in reference to a roundhouse fire would be 6998-F.

Table I

1st Digit of File	2nd Digit of File	3rd Digit of File	4th Digit of File
(1) Steam locomotives	(1) Material	(1) Reports	(1) Timekeeping
(2) Elec. locomotives	(2) Machinery	(2) Investigations	(2) Pay checks
(3) Gas electric equipment	(3) Lubrication	(3) Instructions	(3) Accounting
(4) Special equipment	(4) Coal	(4) Agreements	(4) Enginemen
(5) Power plants	(5) Fuel oil	(5) Permits	(5) Shopmen
(6) Roundhouses	(6) Elec. power	(6) Federal laws	(6) Other employees
(7) Heavy repair shop	(7) Additions and betterments	(7) Accidents	(7) Discharged employees
(8) Labor	(8) Wrecks	(8) Train delays	(8) General
(9) General	(9) General	(9) General	(9) Unassigned

Letter index box or folder also required

The best method of handling this filing system is to make two copies and attach one to the main file, the other being put in a letter index correspondence box or folder corresponding to the first letter of the person the letter is addressed to. A new letter index box should be used every month or as often as necessary. The monthly system generally gives the most satisfaction. The file number should be on each carbon copy as well as on the original letter. The purpose of putting the second copy in the index box is to interlock the files for protection against replying letters giving the wrong file number or not mentioning the file number, but referring to the date of the letter. In this event the procedure would be to go to the box file for the month referred to and under the letter as previously explained find the letter of the date referred to; and obtain from it the proper file number. With this file number in mind go to the main file and obtain the correspondence desired, and pin the entire correspondence together. The file is now ready to be passed to the correspondent. The box index letter should never be taken out of its place unless absolutely necessary, as this

The type of filing system in use has an important bearing on office efficiency

is the interlock which protects against replying letters with an incorrect or no file number. If neither date or file number are given, then the correspondence must be classified until the proper file is obtained. This, however, is seldom necessary where a conspicuous red letter stamp at the top of the outgoing letter requests that (In reply please refer to file ——).

Disposition of dead files

After several years of files have accumulated a great many dead files in the filing cabinet can be permanently filed away in the record room. In order to expel dead correspondence from the files it is only necessary to put a hypen between the new file's first and second digit as 1-873-A. Build the new files as previously, and bring the live correspondence over into the new files as it comes up, leaving the remainder in their folders until such time as the live correspondence has been transferred into the new files. The old files can then be filed away in the record room and need only be brought out when something comes up of a very old date.

The disadvantages of this particular system are:

1—The above filing system in rare cases allows two different files to be put away under the same file number. However, there is always a relation between the letters in the same file folder. If files pertaining to each are always kept pinned together no trouble will be experienced.

2—A separate card reference must be kept to trace letters which have not been answered in the time desired.

3—Two copies of each letter must be made, but bearing in mind that it takes no longer to make two copies than it does one, except where the stenographer needs to use an eraser a great many times, the only objection is the exta sheet of paper needed. In view of the fact that very cheap paper can be used for the carbon copies, this is not a serious objection.

The advantages of this system are:

1—The file number can easily be put on the outgoing letters.

2—This system can be installed any time.

3—Obsolete files can be eliminated at any time.

4—Any one can learn to operate the system quickly.

5—This method has an interlocking system which can be operated quickly.

6—This method groups allied correspondence close together.

7—By allowing unassigned numbers vacant new subjects can be assigned numbers.

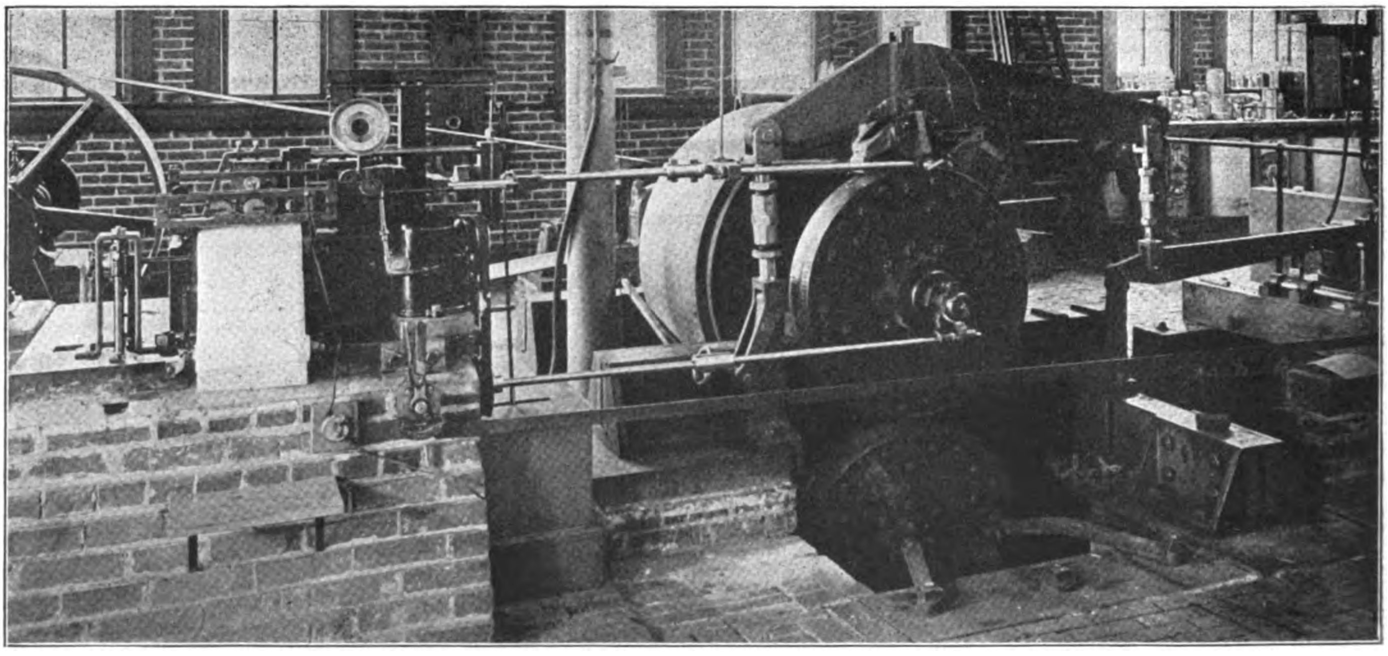
231,088 files are possible

Some idea of the available file numbers can be obtained from a study of the combinations that can be made by four digits of figures whose numbers lie within 9,999 and 1,111 or a sum of 8,888. Then the 26 letters in the alphabet make a possible of 26 times 8,888 or 231,088 possible files.

With 231,088 possible files, the possibilities of such a system can easily be understood. This system can be used by an entire mechanical department. The highest officer in this department need only assign various prefix letters to each subordinate officer. Any file originated by the highest officer will have his prefix, and in like manner files originating from subordinate officers will have theirs.

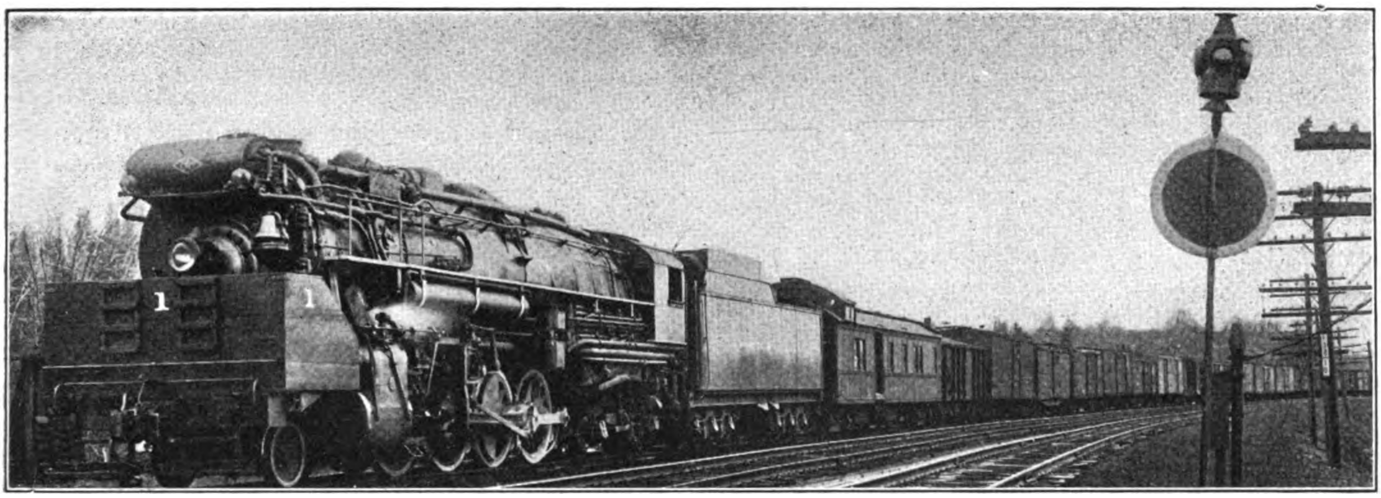
A mechanical officer whose duties compel him to write letters while traveling can do so by using the classification as a guide, and it will not interfere with his main office, even if he does not classify exactly as his file clerk does in the main office. The only difficulty that this may at times bring about is that the interlock system of ascertaining the file number by classification, which should only be used as a last resort, might not be as efficient. However, this is not a serious objection, and the other advantages gained by being able to file while on a business or inspection trip will more than offset this disadvantage.

This filing system affords an easy method of naming all correspondence quickly; the name is a number which, when referred to by the replying letter, automatically tells where to find the file. In the event that the file number is not referred to, several different quick methods can be applied to ascertain the proper file number.



Brake shoe testing machine installed at Purdue University by the Master Car Builders' Association in 1898

More than 500 brake shoes have been tested for wear and coefficient of friction since its installation. It is available for use at any time for investigation work by the Mechanical Division of the American Railway Association



The locomotive and a test train on the Albany division of the Boston & Albany

2-8-4 locomotive tested on B. & A.

Tests show satisfactory performance of new features of construction—Develops high fuel economy

By F. A. Butler

Superintendent motive power and rolling stock, Boston & Albany

ON page 267 of the May, 1925, issue of the *Railway Mechanical Engineer* there appeared a description of the new 2-8-4 type locomotive which was built by the Lima Locomotive Works, Inc., and placed in service on the Boston & Albany in February, 1925. In this article mention was made of the fact that the locomotive was undergoing tests in service, from which data would later be available. This article contains a summary of the results obtained in those tests.

This locomotive, which was designated as No. 1, was received at the Boston & Albany enginehouse at Selkirk, N. Y., on February 18, 1925. Two days later it was placed in regular freight service on the Albany division of that road and after a short period in regular freight service, test apparatus was applied at the West Springfield shops. The first test trip with the dynamometer car was run on March 28, 1925.

Test equipment

The test equipment included New York Central dynamometer car No. X-8006. Indicators were placed on the cylinders of the locomotive and gage glasses were applied to the corners of the tank to measure the water. The tank was calibrated by weighing water in a barrel mounted on platform scales on top of the tank. A slope bottom coal box mounted on platform scales was applied to the tender for measuring coal.

Steam gages were applied at the dome, to the saturated side of the superheater header, to the superheated side of the superheater header, to the steam chest, to the exhaust passage, to the steam space of the feed water heater, to the feed water line at the boiler check, to the steam line to and to the exhaust line from the locomotive booster.

Thermometers were applied to both steam pipes close to the steam chest and to the exhaust passage on the left side. Thermometers were also applied in the tender tank, in the water line to the feedwater heater, in the water line from the feedwater heater, in the exhaust steam line to the feedwater heater and in the condensate line from the feedwater heater. Pyrometers were applied to the superheated side of the superheater header and in the smoke box.

Provision was made to read the draft in the firebox,

in front of and in back of the diaphragm. A summary of the data collected is given in the tables.

Operating conditions

The Albany division is between Selkirk, N. Y., and Springfield, Mass., a distance of approximately 100 miles. The tests were run east bound from Selkirk to Washington, which is at the top of the grade, a distance of 60 miles. A condensed profile of the line is included which also contains certain operating data as well as the profile. The Albany division has many curves, but no attempt has been made to show these on the condensed profile.

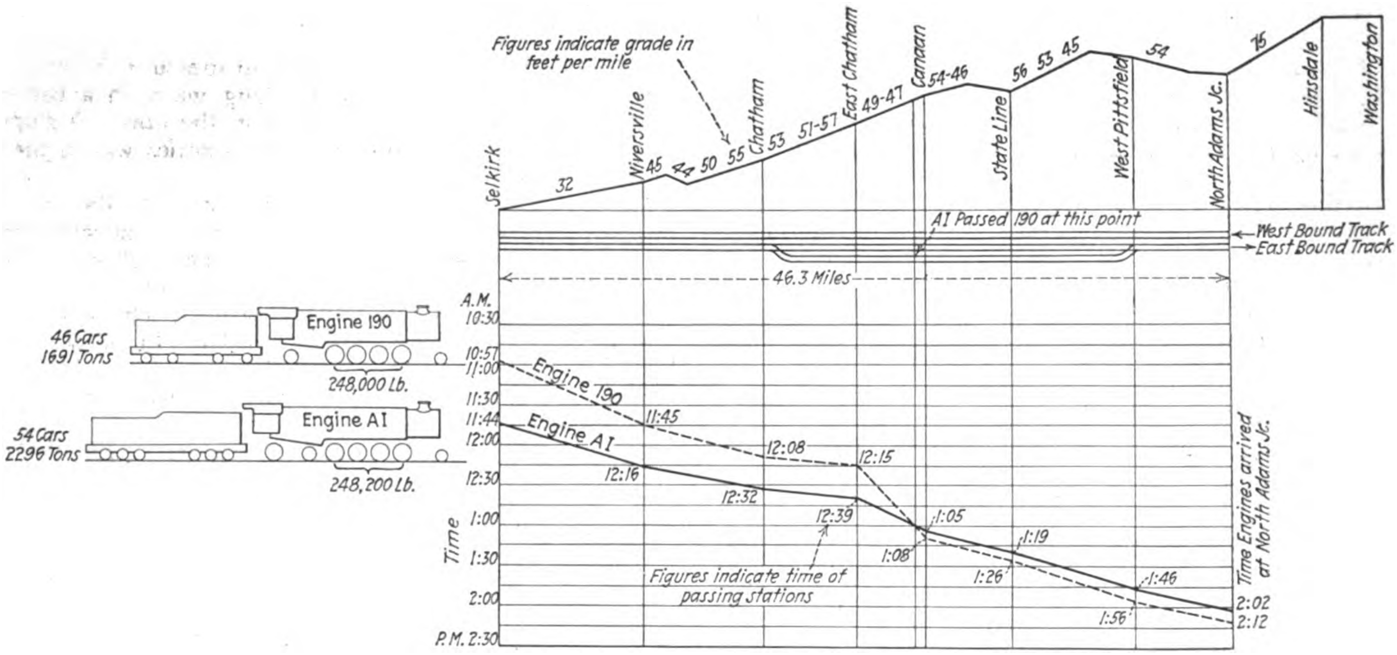
Under normal conditions the volume of freight and passenger traffic closely approaches the capacity of the track. Therefore, any increase which can be effected in the size of the train unit and the speed of operation relieves this condition.

Nine reliable tests were made between March 28 and April 18. During this period the weather conditions were variable and at times the condition of the rail was poor, as light snows were encountered. The average atmospheric temperature for one complete test was 43 deg. F. The tests were run under normal operating conditions and the results, therefore, reflect the performance of the locomotive in regular service.



Profile of the Albany Division, showing the comparative test run of locomotive No. 1 and a Mikado locomotive

All figures are given as average over the test division including the effect of all variations of power output, from the maximum to the minimum which go to make up the average, and hence are valuable as data which can be used to make comparisons and predictions in regular train operation. For this reason no attempt was made to correct for grades and curves where these factors might enter into the final results.

Average boiler and engine performance

The efficiency of the steam generating plant ran from 72.75 per cent to 89.51 per cent, the average of all runs being 80.5 per cent. The relation between coal rate and efficiency is shown in one of the diagrams. This high average was the direct result of the large grate area and firebox and the boiler equipment. The large grate area gave an average coal rate per square foot per hour of 52.66 lb. for all runs. The large firebox and the Type E superheater which permitted a maximum gas area through the tubes and flues, together with the feedwater heater produced an average evaporation of 8.13 lb. of water per lb. of coal as fired. The equivalent evaporation per lb. of dry coal was 11.37 lb., average.

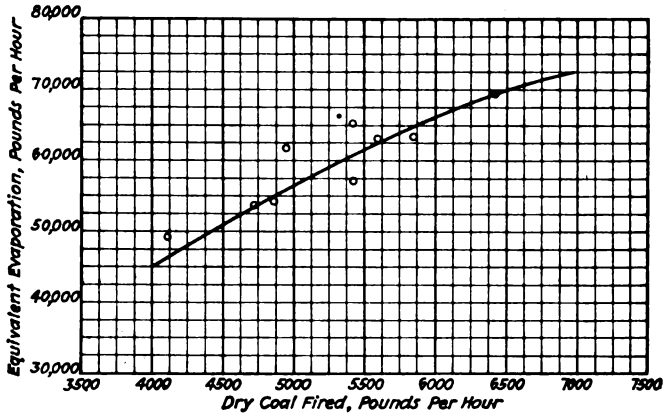
The smoke box temperatures clearly reflect the ability of the firebox and boiler to absorb heat. These figures ran from 543 deg. F. to 599 deg. F.

The boiler pressure of 240 lb. per sq. in. and the limited cut-off enabled this engine to produce an average of 1923.7 indicated horsepower with an average cut-off over the test division of 43.7 per cent. This resulted in an average water rate per indicated horsepower-hour of 20.16 lb. The coal per indicated horsepower-hour was 2.44 lb., average, with a maximum of 2.67 lb. and a minimum of 2.34 lb. The maximum cylinder horsepower recorded was 3,675.

The dry coal per dynamometer horsepower-hour averaged 3.13 lb., with a maximum of 3.41 lb. and a minimum of 2.83 lb. The maximum drawbar pull was 76,800 lb., of which the booster produced 11,800 lb. The maximum sustained drawbar horsepower recorded was 3,240.

The locomotive as an operating unit

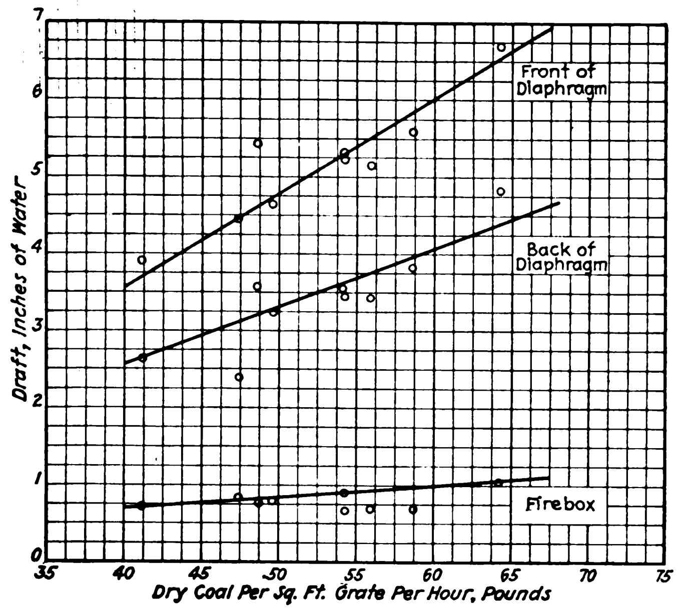
Reference was made in a previous paragraph of this article to the severe operating conditions on this division



The relation between boiler output and coal consumption

due to the great number of trains to be moved and the relief it is possible to obtain by increasing the size of the train unit and the speed of operation. To effect this requires an increase in gross ton-miles per hour per locomotive, which in turn means a corresponding increase in dynamometer horsepower per locomotive.

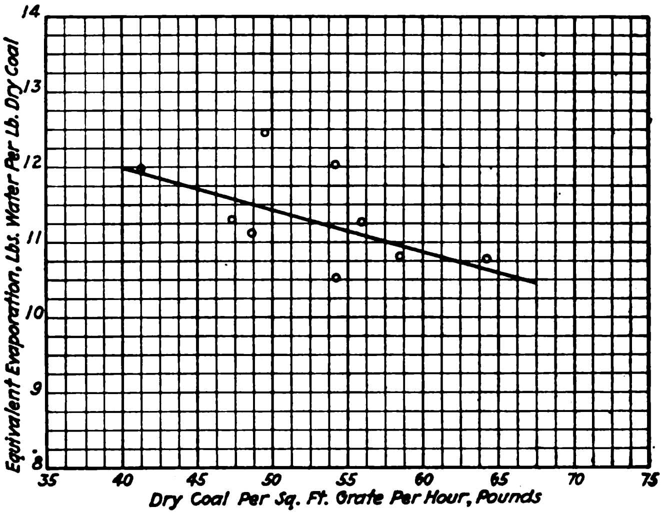
Probably the clearest comparison in this regard between the 2-8-4 type engine and the Mikado type now used on the Albany division (the principal dimensions



Variation of the coal rate in relation to the draft

of which were compared with those of the 2-8-4 locomotive in the description of the latter in the May, 1925, *Railway Mechanical Engineer*, was the test run of April 14, 1925. This comparison is shown in the diagram below the drawing of the profile of the division.

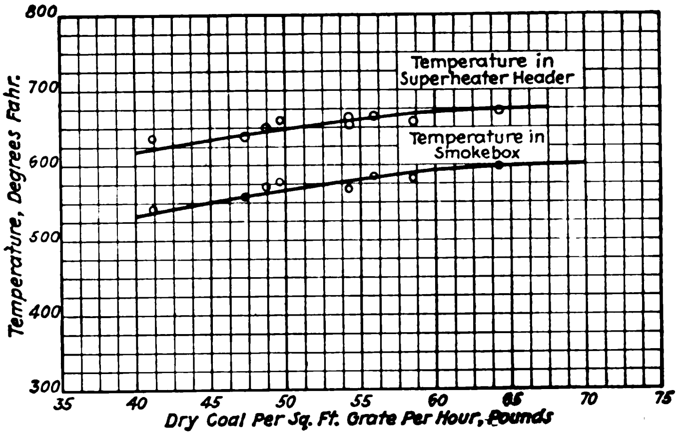
On this day Mikado engine No. 190 started from Selkirk with a manifest train of 46 cars, 1,691 tons, 47 minutes ahead of the 2-8-4 type class A-1 which had 54 cars, 2,296 tons. Both trains ran without delays, the A-1 overtaking the No. 190 at the point shown on the diagram. At Chatham, No. 190 took the outside track so that at the time of passing the two trains were running side by side on parallel tracks under exactly the same conditions. Between East Chatham and Canaan is a difficult part of the line, with many curves and a heavy



The relation between the coal rate and the rate of evaporation

grade, the severity of this part of the line in comparison with other sections having similar average grade conditions not being adequately shown by the profile.

This run may be taken as a fair comparison of the relative ability of the two engines to move freight over the line. The uniform speed of the 2-8-4 type locomotive over the test division is noteworthy as indicated by the uniform slope of the time curve.



Relation between the coal rate and superheater and smokebox temperatures

The following data compiled from the test result of the two locomotives is a comparison on the basis of gross ton-miles and fuel.

Average dynamometer horsepower, which is proportional to gross ton-miles per hour

Average lb. dry coal fired per hour	A-1	Mikado	Per cent increase A-1 over Mikado
4,000	1,200	†	...
4,500	1,350	†	...
5,000	1,480	1,200	23.5
5,500	1,600	1,250	28
6,000	1,750	1,320	33
6,500	*	1,420	...
7,000	*	1,550	...
7,200	*	1,650	...

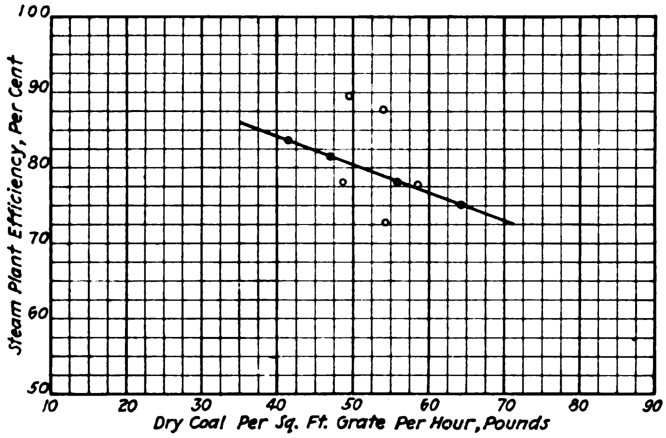
*The A-1 never reached these rates of firing.
†The Mikado never ran at as low rates as these during the tests.

Further details of the test data are shown in the tables

of engine and boiler performance. Charts showing a number of pertinent relationships with respect to the coal rate per sq. ft. of grate per hour, the coal and steam consumption rates and the thermal efficiency, calculated from this data, are also presented.

Performance of the new features of construction

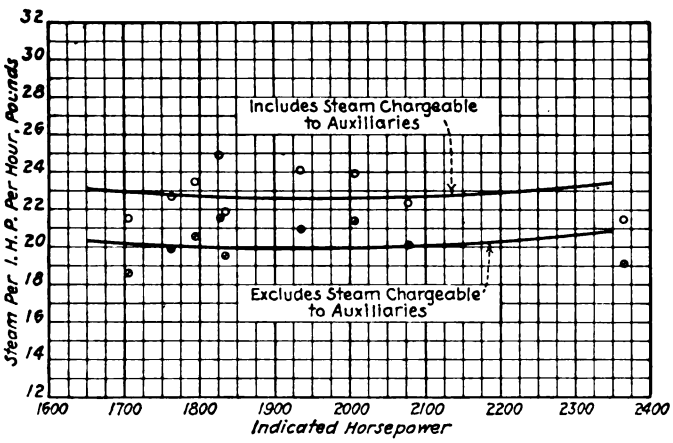
Many new features of construction were incorporated into the design of the Class A-1 locomotive. As these are vital elements in the economic performance of the



The efficiency of steam generation in relation to the coal rate

engine, their operation was noted with special care to determine their adaptability and usefulness under service condition. The principal new features, which were described in detail in the May, 1925, issue of the *Railway Mechanical Engineer* are the compensated limited cut-off in the cylinders, the cast steel cylinders, the articulated main rod drive, the articulated trailing truck and the large grate area.

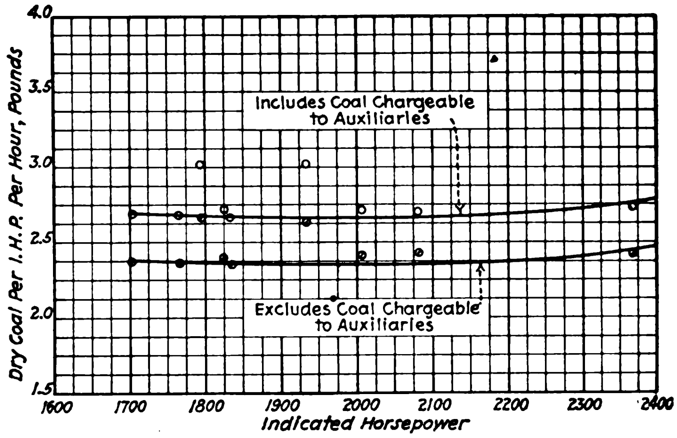
Trials were run to determine the best point of cut-off consistent with prompt starting under the worst conditions of rail, grade and position of the cranks. It was



Steam consumption in relation to indicated horsepower output

found that 60 per cent maximum cut-off best met this condition. With this cut-off an indicated tractive force of 69,400 lb. was obtained at slow speeds. The indicator cards gave a very even turning moment with the result that with this tractive force, giving a factor of adhesion of 3.58, there was no more tendency to slip than there would be with a full stroke cut-off engine, having the same driving wheel load and developing 63,500 lb. tractive force. Prompt starting was secured under all conditions.

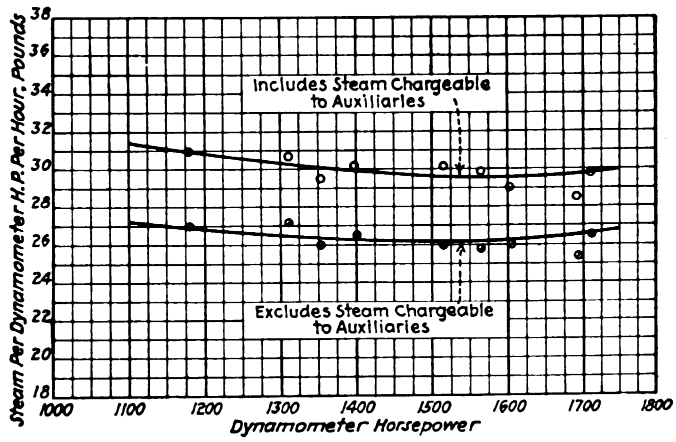
With respect to the cylinders, the only comment which can be made after a limited time of operation of about three months is that the cylinders showed no signs of



Dry coal consumption per indicated horsepower

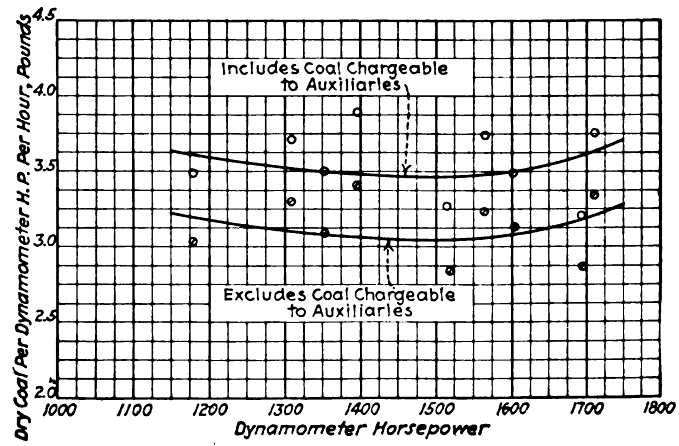
weakness and that all the joints of the exhaust passages remained tight. In fact these joints were never touched during that time.

No trouble was developed with the new type of rod



Steam consumption in relation to dynamometer horsepower output

drive, the same bearings with which the rods were first equipped remaining in place throughout the test. No hot pins or main boxes trouble developed, although with

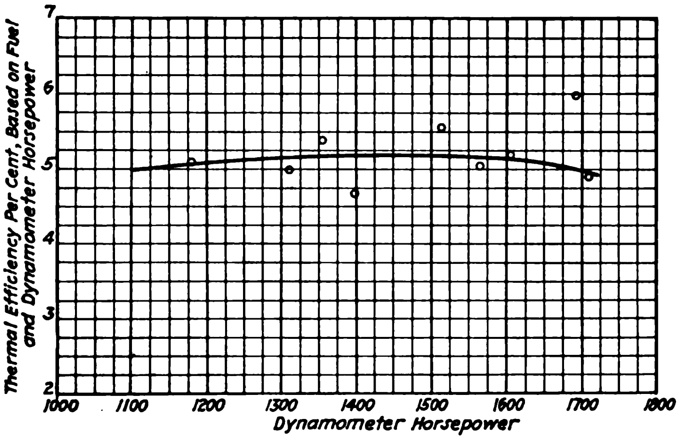


How the rate of coal consumption varied with the dynamometer horsepower output

240 lb. pressure the piston thrust is 148,000 lb. Measurements of the wear on the main and rear boxes were made to determine whether the piston thrust was being dis-

tributed by the rod drive over two pairs of boxes. These measurements showed almost exactly the same horizontal wear in the back as in the main brass thus indicating the correctness of the theory that this rod drive distributes the thrust over two pairs of wheels. Final confirmation of this, however, can only be obtained after more extended service.

No trouble of any kind was experienced with the tracking or operation of the articulated trailing truck and it seemed to adapt itself very well to the track conditions. The engine rode steadily up to the highest operating speeds which the service required. Particular comment



The thermal efficiency at the drawbar

is made upon the large ash pan and the ease with which it can be dumped. The accessibility of the booster and stoker is also worthy of note from a repair and maintenance standpoint.

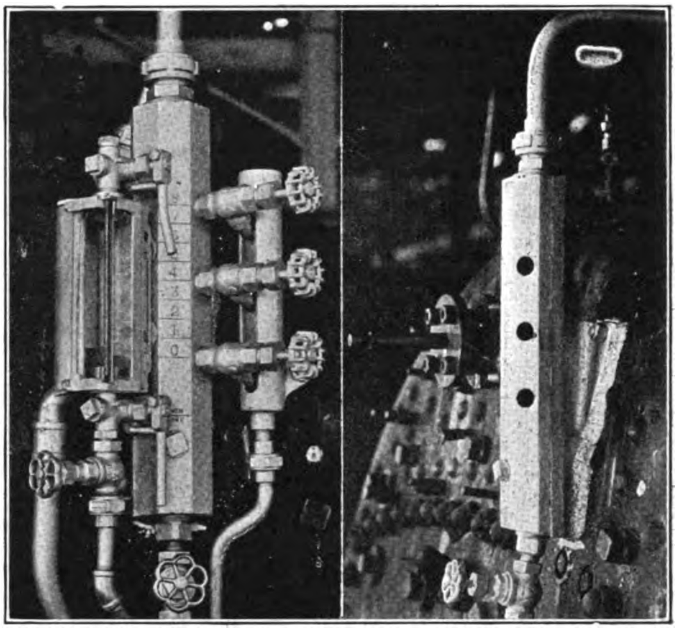
Observations were made to determine if under conditions of very light work proper combustion would be supported over the large grate area. No trouble from this cause was experienced and rates of firing as low as an average of 41 lb. of coal per sq. ft. of grate per hour over the test division were recorded.

Compact cast steel water column

IN view of the interest being shown by the railroad field in the question of satisfactory water columns, the accompanying details of the L. & C. cast steel water column, which has become standard on the Canadian National, should offer useful suggestions to those working on this problem. Up to the present time over 300 locomotives have been equipped with this column. It is of a compact and rigid design and is welded directly to the backhead of a boiler without the use of separate brackets. This method keeps the application close enough to the face plate to give the engineer an unobstructed view of all gages. This condition, together with the elimination of bolts or studs for securing it to the boiler, is a particular feature of the L. & C. column. The welding pad which is cast integrally with the column permits over 30 in. of welding and this pad is so designed as to fit on to a locomotive boiler without covering any tee-iron rivets.

The first L. & C. columns applied had a bore of 2 in., but later applications were given a 3-in. diameter bore. The bottom connection into the boiler, which is made of cold-rolled brass, is provided with a ¾-in. opening and is applied in such a manner as to provide additional fastening to the boiler. By removing the plug in the face of the column, the bottom connection can be readily cleaned.

The water glass mountings are applied directly into the column in such a position that they project the least possible distance beyond its face while still being easily



General view of water column and method of welding to backhead

visible to both the engineman and fireman. In the case of the Canadian National mountings, they project only 2½ in. beyond the face of the column.

FREE AND EASY.—The following account of an accident caused by an explosion in an empty tank car, published in Bulletin No. 67, Bureau of Explosives, is pointed in its lesson, as well as in its style:

"Because of a shortage of space, this one had to be left out of the preceding bulletin, but really, it is too good to miss. If your own ears burn when you read it, please note that no names have been mentioned, and gratefully accept the opportunity to turn over a new leaf.

"A freight train stopped somewhere along the line. In the train was an empty tank car which had previously contained gasoline. A couple of tramps came along, looking for free transportation to some region where handouts were freer and bulldogs more scarce. As a rule, a freight brakeman loves a tramp to about the same degree that a dog adores a cat; but in this particular instance the flag-bearer must have recognized a personal friend or something, for he cast about for a place wherein the brake-beam acrobats might ride without being detected.

"Aha! the empty tank car! Realizing that there might be vapors in the car even stronger than certain characteristics of the average tramp, the brakeman took the most dependable, as well as the most sudden, way of finding out. In other words, he lowered his lighted lantern through the dome!

"It really seems superfluous to go on. Our sentiments concerning the whole affair are most forcefully (though unintentionally) expressed by a paragraph from the B. E. Form 25, on which the case was reported. This paragraph is as follows, the numbers referring to numbered questions on the form:

"1—Blank! 2—Blank!

"3—Brakeman was inspecting interior of empty tank car to see if O. K. for trespassers to ride in it. As he lowered his lantern into the dome, gas explosion occurred, severely burning the brakeman and a trespasser about the head, neck, hands and arms. Brakeman will be incapacitated for a period of about three weeks.

"4—Blank. 5—Blank!

"The exclamation points are our own. The thought occurs that if the brakeman was burned about the head, possibly some charcoal was formed."

Safety first competition

By H. L. Needham
Master mechanic, Illinois Central, Clinton, Ill.

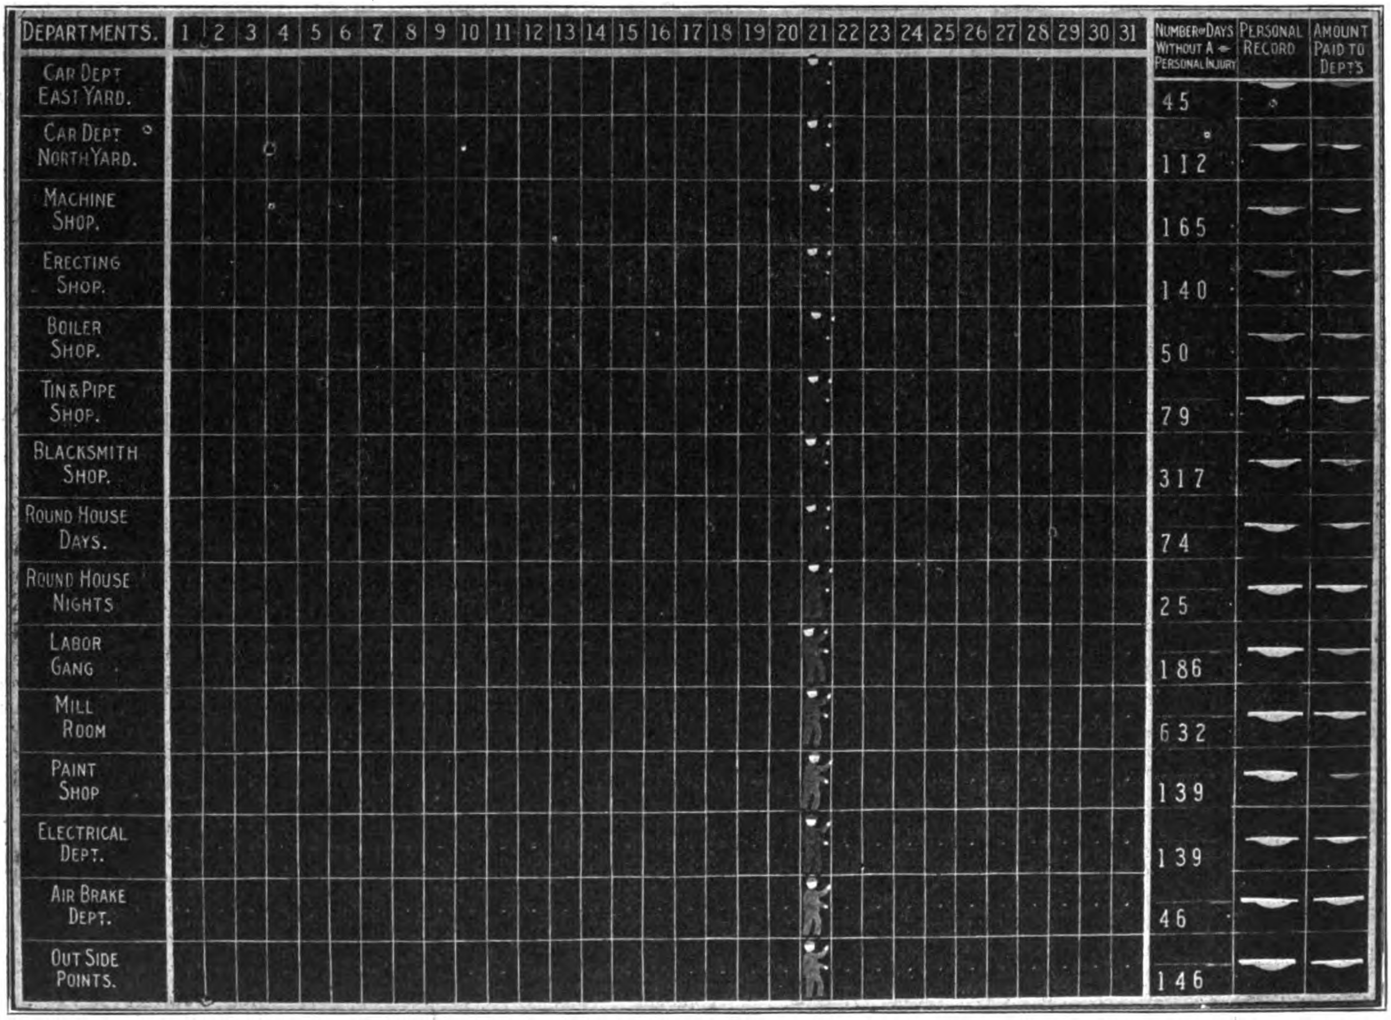
COMPETITION in safety first records is encouraged in the Clinton shops of the Illinois Central by means of the 63-in. by 90-in. board illustrated. At the top of the board the days of the month are indicated and at the left the various departments in the back shop, enginehouse and car repair yards. On the right of the board are three columns, one of which indicates the number of days which have elapsed without a personal injury and the other two containing pockets for personal record cards and cards indicating the amount of money paid to injured men.

About 700 shopmen are employed in 15 different departments, each of which is represented by the figure of a man which may be moved about on the board at will. Should a personal injury occur in one of the departments the figure is left standing at the date when the injury occurred, the name of the man being written on a small T-card and attached to the figure by a flap which slips in a pocket provided for this purpose. The figure remains on that date until the close of the month, an additional figure being started in its place. Should a second man be injured in that department the second figure is left on the date on which the injury occurred, and in this way at the end of a month there are as many figures on the board for each department as there have been accidents in the respective departments.

The use of this board keeps before the supervisory officers the names of the men who are injured, the department in which each works, the number of days which have elapsed without a personal injury, together with the amount paid in compensation. Healthy competition between the departments is stimulated.

The board illustrated was put in use May 1, 1925. During the month of May, 1924, 11 injuries were reported in the mechanical department at Clinton, there being none in May, 1925. In June, 1924, 11 injuries were again reported, there being two in June, 1925. A similar improvement was made in July. In other words, and four injuries during a similar period in 1925.

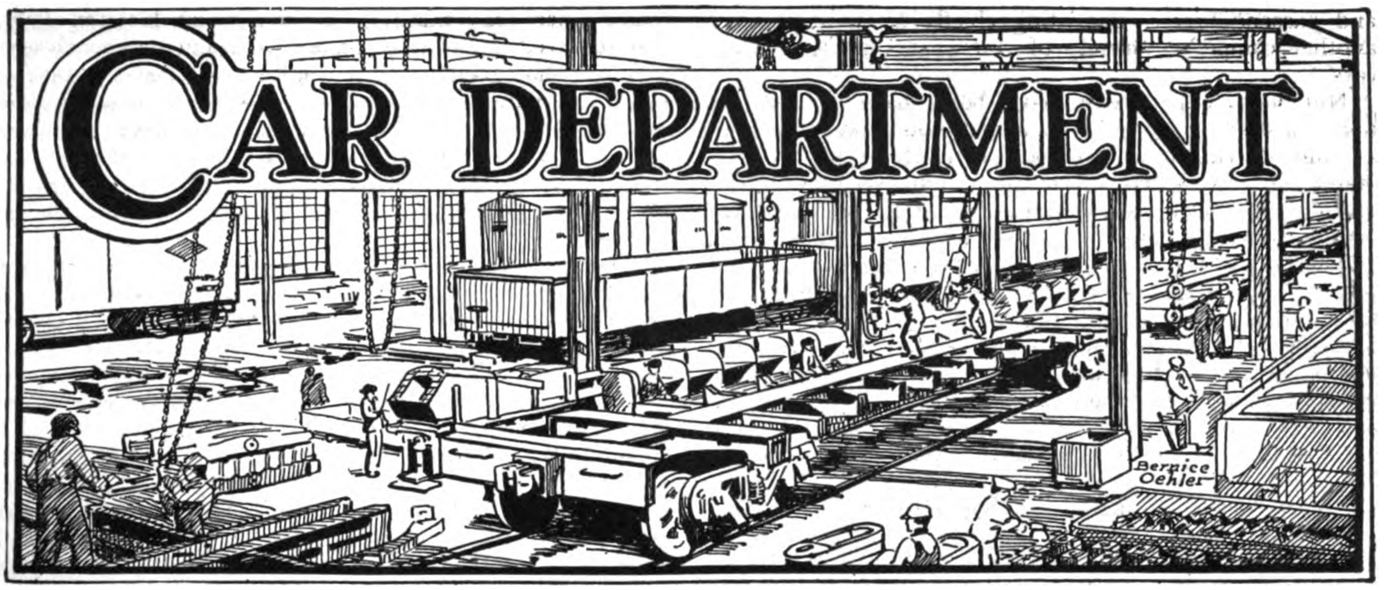
Much interest has been shown in the matter of safety since this arrangement for visualizing results was put into effect. Each department endeavors in every way to keep from having an accident which will spoil the record of "number of days without a personal injury." Moreover, the employees do not want their names to appear on this board and consequently do everything in their power to prevent getting injured.



Safety first board used at Illinois Central shops, Clinton, Ohio

---

A SECOND WASTE RENOVATOR and oil reclaiming machine has been installed at its shops at River Rouge, Detroit, by the Detroit, Toledo & Ironton, and is reclaiming an average of 80 gal. of refined oil and 260 lb. of clean waste daily. The operation has been simplified to such an extent that the cost has been reduced considerably below the value of the oil and waste reclaimed.



Car inspectors and foremen hold twenty-fourth convention

Opening sessions featured by papers on lubrication and progressive freight car repairs

THE twenty-fourth annual convention of the Chief Interchange Car Inspectors' and Car Foremen's Association of America was held at the Hotel Sherman, Chicago, September 22, 23 and 24. The sessions were presided over by President C. M. Hitch, a total of 549 members and guests being registered in attendance at the convention. Short informal addresses were delivered by F. H. Hammill, executive vice-president of the Chicago, Rock Island & Pacific, and F. W. Brazier, assistant to the general superintendent of rolling stock, New York Central. Among the individual papers presented were Progressive System of Freight Car Repairs, by F. A. Starr, general car inspector of the Chesapeake & Ohio; Lubrication, by L. R. Christy, general car inspector of the Missouri Pacific; A. R. A. Billing and Preparation of Records, by L. Martin, chief accountant, A. R. A. Bureau, Baltimore & Ohio, and Prevention of Transfers and Transfer Claims, by F. S. Cheadle, chief car inspector, Richmond, Fredericksburg & Potomac. Abstracts of these addresses and the convention proceedings will be published in this and succeeding issues of the *Railway Mechanical Engineer*.

New officers elected

The following officers were elected for the ensuing year: President, W. P. Elliott, general foreman, Terminal Railroad Association of St. Louis, East St. Louis, Ill.; first vice-president, B. F. Jamison, special traveling auditor, Southern, Meridian, Miss.; second vice-president, E. R. Campbell, general car foreman, Minnesota Transfer, St. Paul, Minn.; third vice-president, M. E. Fitzgerald, general car inspector, Chicago & Eastern Illinois, Danville, Ill.; secretary and treasurer, A. S. Sternberg, master car builder, Belt Railway of Chicago, Chicago. The following were elected members of the executive committee to serve two-year terms: F. A. Starr, general car inspector, Chesapeake & Ohio, Covington, Ky.; L. R. Christy, general car inspector, Missouri Pacific, St. Louis, Mo.; and W. R. Rogers, chief interchange inspector, Youngstown, Ohio.

Lubrication

By L. R. Christy

General car inspector, Missouri Pacific, St. Louis, Mo.

The problem of bearing lubrication is the oldest of all lubricating questions. As we review its development since man first conceived the idea of vehicular movement with bearing surfaces, we find that innumerable improvements have been made in the designs of journals and bearings, the refining of lubricants and methods pursued to insure correct practice. It is obvious that the future will unfold further advantages over our existing standards of lubrication.

Selection of materials

In the purchase of waste, it is essential that the material be free from rags, knotted fibre, particles of metal, grit and other foreign substances, and that the strands be of sufficient lengths. To insure this, the waste should be bought on specifications sufficiently rigid to permit of rejection of material which does not meet these requirements. The waste must have properties that give the necessary degree of resiliency to insure proper contact with the journal at all times, and be capable of conveying the oil to the journal with sufficient rapidity to maintain the lubricating film without breakage. There seems to be a fairly unanimous agreement that the two standard types of waste are preferable: one for use on locomotives

and passenger cars, consisting chiefly of wool strands; another composed entirely of cotton strands for freight cars.

Numerous experiments have been made in order to obtain a bearing metal formula that would cause the least amount of friction, and yet be sufficiently strong to withstand pressure without crushing. Our standard lining metal is a tri-metal alloy, consisting of 85 per cent lead, 10 per cent antimony and 5 per cent tin. This closely follows the recognized standards of a great many of the principal railroads, and is a satisfactory formula. A lining metal of this kind, due to the greater proportion of lead in the formula, will, within a short time, conform to the contour of the journal and reduce the unit pressure to a minimum. In the purchase of new journal bearings, and where old journal bearings are relined by outside companies, it is advantageous to have the test departments of the railroads make periodical inspections at such plants to determine whether proper compositions are used.

We can ill afford to discuss the subject of lubrication without considering the laws of friction, as it is apparent that, were there no friction, there would be no necessity for interposing a lubricant between the journal and journal bearing. The primary object of bearing lubrication is to provide a lubricating film between the rubbing surfaces, and thereby replace the metallic friction with fluid friction, so far as possible, and then, to minimize the fluid friction in the oil itself. Fluid friction is independent of the pressure of the surfaces in contact, but is directly proportional to the area of the rubbing surfaces. If we will give but a moment's thought to this statement, we will realize that it is true, because, each infinitesimal particle of oil will retard the movement of the entire body of oil, and, as the viscosity of the oil increases, so will the fluid friction. Compare the flow of oil from a receptacle, first using a light car oil and then a heavy valve oil. The light car oil will flow from the receptacle more readily because its fluid friction is lower than that of the valve oil. It must be remembered, however, that, as the temperature of the bearing increases, the viscosity of the oil decreases, and the body of the oil must be such that it will maintain the film without breakage at the normal running temperature of the journal. Experiments conducted to determine the relative temperature of the journal, the bearing and the lubricant have indicated that the temperature of the lubricating film is higher than that of either the journal or the bearing. It therefore follows that the least viscous lubricant not unduly influenced by great variations in temperature is the most desirable car oil. The oils which best satisfy these requirements are mixtures of mineral oil and suitable fixed oils.

Renovation and saturation of packing

The company with which I am connected, arranged during the current year for the installation of waste renovating plants of modern design at two of its principal shops. All journal packing removed from locomotives, passenger cars and freight cars, in addition to waste used in shops, is forwarded to these plants for renovation. The journal packing thus reclaimed is also re-impregnated at these plants, as is the saturation of new packing, and this material completely prepared for immediate use, is apportioned to the various shops, repair and inspection points, as needed. It seems to the writer to be of sufficient interest and probably value to relate the process as it obtains and the results achieved in this manner.

The packing removed from journal boxes, and the discarded waste in shops is placed in specially constructed metal containers, of approximately 300 lb. capacity, and bearing necessary markings to distinguish between packing removed from locomotives, passenger cars, freight cars and shop waste. As promptly as sufficient quantities are accumulated at any point, shipment is made to the nearest renovating plant. These same containers are used, of course, in forwarding packing to the various locations, and in this manner sufficient containers are always available at both the plants and the outlying points on the railroad.

When consignments are received at the plant, the contents of each container are weighed, inasmuch as a complete record is kept of the material received and issued to each point, which affords a positive method of determining whether or not all old material is returned.

The waste is first placed in metal trays, where the larger pieces of babbitt, cinders, small stones and other similar foreign substance are removed. This requires only a few minutes to each container of packing. The next operation consists of placing the waste in a heating tank, where it remains approximately 20 min. immersed in oil, at a temperature of 130 to 140 deg. F. It is then forked up on a drain board and drained for a period of from three to five minutes. Then, the waste is removed to a motor driven centrifugal extractor, which is equipped with a filtering arrangement, and rotated for five minutes at the rate of approximately 1,200 r.p.m. At this stage of the process most of the oil has been removed, filtered and drained into an underground storage tank. After this operation, the waste is conveyed to a motor driven cleaning and drying machine, where the dirt is thoroughly removed from the material, and it is dried within 12 min. This machine is equipped with steam coils and air intake fan and operates under air blast at a temperature of 180 deg. F. The cylindrical container oscillates after making two and one-half revolutions in either direction. When the waste is removed from this machine, it has been thoroughly renovated and is ready for saturation in the waste impregnator. This device, by the combined use of a vacuum pump and compression head, actually accomplishes the complete saturation of the waste in less than five min. In preparing packing from the renovated waste, only the reclaimed, filtered oil is used, which is pumped from the underground storage tank to the impregnator. Past experience has shown that one gallon of surplus oil accrues to each 100 lb. of waste renovated. In other words, slightly more oil is recovered from this amount of renovated waste than is consumed when it is again saturated. It has been demonstrated that oil does not wear out in service, but simply becomes contaminated with foreign matter, and after proper reclamation is, in reality, as good as new oil. New oil is used with new waste in preparing new packing. In no case is new packing mixed with renovated packing.

An electrically operated machine for making packing rolls is also contained in this system.

The capacity of each plant is two and one-half million pounds of renovated packing per annum, which reduced to an average daily production, amounts to 9,000 lb. The services of five men are required in connection with the operation of each plant.

This system has many varied advantages over the ordinary methods of reclaiming and saturating packing. You have perceived that the entire operation of renovating and saturating the packing requires less than one hour, as compared with 48 hours, which is the usual length of time waste is subjected to immersion, not to mention the labor incident to cleaning waste by hand. Without doubt, the packing is decidedly cleaner and the oil penetration is better. By concentrating this work into fewer plants of greater capacity, and modern design, a large number of small obsolescent plants were abandoned.

Aside from the improved mechanical features mentioned, this concentration alone insures both economy and uniformity of practice. With both, a substantial saving is possible, owing to the greater percentage of oil and waste reclaimed, including the used shop waste converted into freight car packing, and a corresponding decrease in new oil and waste issued. Moreover, the extravagant use of materials is minimized, if not entirely eliminated, by this procedure. Wasteful practices are more difficult to correct where the packing is prepared at numerous points, as it is evident packing indiscriminately made is not always properly drained, nor is all old packing accounted for, as it is often left in train yards, thrown in outbound cars, used in firing locomotives, or otherwise discarded, unless there is some definite means to keep a record of the consumption. This process also largely precludes the use of free oil which is such an expensive factor in lubrication.

Considerable discussion has ensued at these meetings with respect to conditions contributing to hot boxes, as well as the proper method of packing boxes. It follows that the causes are generally understood, and doubtless there is but a slight divergence of opinion concerning the packing of boxes, which is largely restricted to the advisability of applying a filler, or plug, at the front of the journal box. Reasoning on this basis, it is apparent we should then determine whether the correct practices are followed. Have we assured ourselves that inspection forces are sufficiently alert in their efforts to discern the various defects that result in hot boxes? Are we certain that oiling forces in train yards are giving necessary service treatment to cars, and that sufficient dexterity is shown with the packing iron?

Considering the importance of the proper use of the packing iron, it is surprising how frequently this attention is neglected. I am inclined to believe that few railroads have standard packing irons and packing hooks, as is evidenced by the miscellaneous assortment in use. Many of these are of such dimensions and construction as to prevent oilers from obtaining best results. A satisfactory means of fixing individual responsibility for improperly packed boxes, is to assign to each oiler a symbol number, with alphabetical prefix to designate terminal or division, and require him to mark this symbol on both sides of car when he has given service treatment, or repacked boxes. If trouble subsequently develops at any point on the railroad, due to improper attention, it is possible definitely to place responsibility with the oiler at fault.

It is conceded that cars ordinarily do not remain in train yards for a period sufficient to make a thorough inspection of packing in all boxes, and to completely adjust packing, or repack boxes when necessary. In view of this condition, it behooves us to give thorough attention to cars when on repair tracks where facilities are available. In such instances, the packing should be entirely removed and each box repacked at designated intervals. The necessity of complying with this practice cannot be too forcibly emphasized, and if each railroad will actively pursue a program of this kind, an appreciable reduction in the number of hot boxes will be made. During the time the car is on the repair tracks, reasonable precautionary measures should be taken with respect to the mechanical conditions that contribute to hot boxes. Trucks should be in proper alinement; journal boxes parallel and not unduly worn; tops of boxes free from irregular surfaces, dirt and grit; broken or missing truck springs should be replaced; wedges should not be distorted or otherwise defective. When wheels are exchanged, compound should be thoroughly removed from journals and journal boxes carefully cleaned. Due care should also be exercised in removing worn truck pedestals on passenger cars. The best results are not obtainable when relined journal bearings are used on passenger cars. The periodical jacking of boxes on passenger cars, for the purposes of carefully examining journal bearings, wedges and journals, is advisable and necessary to the successful operation of passenger trains. Our practice is to inspect each passenger car in this manner at three months' intervals. The expense thus incurred is promptly offset by the reduction in cost of caring for hot boxes.

Before concluding, I desire to comment briefly on the intimate relation of supervision to the suppression of hot boxes. Intensive supervision is always a potent factor in this respect, just as it is in connection with various other phases of our work. A single illustration of its significance is that hot box trouble does not long remain in epidemic form at any one point.

Progressive system of freight car repairs

By F. A. Starr

General car inspector, Chesapeake & Ohio, Covington, Ky.

The repairs to freight cars may be divided into two general classes or grades: light and running repairs, which is that class of repairs accruing from current wear and breakages; and classified heavy, general and rebuilt repairs, which is that class of repairs involving the restora-

tion of the car as a whole to first class condition for a period of time.

Scheduling and routing

Many forms of scheduling and routing systems have been developed and successfully installed in locomotive and passenger car repair shops, but only in the last few years has any degree of perfection been reached in the scheduling of freight cars. Fundamentally, such systems are very similar in principle and application to freight cars, and there is no reason for assuming that a system, which has greatly benefited locomotive and passenger car repair shops, will not produce equally satisfactory results in freight car repair shops. The quantity of freight cars repaired automatically induces systematic operating methods; but the scheduling and routing of freight cars is more difficult on account of the large number and many types of cars, and the extensive area over which they operate as compared with either locomotives or passenger cars, which operate over one or two divisions while freight cars operate over the entire road and country. The most successful freight car scheduling is obviously dependent upon large operation and number of cars in the same series, sufficient material and supplies, and a complete organization which will enable men to be highly classified into special gangs. It is not really difficult to handle up-to-date scheduling and routing methods in freight car repair shops, but it may be necessary completely to rearrange or relocate repair tracks, material storage, and associated shop facilities.

Advantages and possibilities of progressive system

It has been conclusively demonstrated that with the progressive system of shop operation there are greater possibilities for economy and efficiency than with any other method yet devised. This system permits of properly organizing the shop forces, systematic delivery of materials at designated points and at defined intervals. It is conducive to specialization of the work by groups and individuals, which is an important factor in production. It lessens the multiplicity of tools and fixed equipment, also simplifies supervision as the men become familiar and more efficient in the execution of the particular operation for which they are responsible, and are induced to devise plans and means, and to provide themselves with suitable tools especially adapted to their portion of the work, which greatly contributes to increasing and improving output and reducing labor costs. The men become better satisfied and more interested in their work, co-operating closer with the supervisor; friendly rivalry or competition arises among the various gangs, striving not only to increase quantity but to improve the quality of work as well. All of these advantages and conditions greatly reduce the probability of personal injury to the workmen.

The only objection raised to the adoption of this system is the effort necessary to collect cars in the same series at the same shop in sufficient number to make the operation a success, and the possibility that work on another series of cars might retard the progress. However, it is possible, except perhaps on smaller roads, to overcome this difficulty by arranging a schedule of classified repairs to freight cars to extend over a period of from two to ten years, and cars in certain series can be shipped to the shop to which that series is allotted from other shop points. The advisability and practicability of shopping cars by series or classes is recognized, and most of the obstacles in this respect have been overcome to the extent that the method has become quite general in its application to heavy and classified freight car repairs.

On roads large enough to so arrange, cars in the same series may be allotted to two or more shops to eliminate all possible empty car haul.

Materials

One of the most important requirements of this system is the prompt delivery of materials, which should be done by tractors or electric driven trucks with trailers, unless the shop is equipped with overhead cranes. No work should be started on the repair schedule until material necessary to complete the program is on hand in sufficient quantities to carry on the work until the remainder required is received, that there may be no hold-up or retarding of the progress on account of shortage of material.

Suggestions for repairs

In the actual work of repairs it is suggested that draft gears, attachments, and center sill construction be sufficiently strengthened, so that the shocks incident to modern service will be absorbed and distributed throughout the car without causing excessive damage to the superstructure. Center sills and draft sills should have sufficient sectional area and should be protected against buckling by the use of cover plates. A common cause of failure in steel cars is due to the bodies of hopper cars not being securely fastened to the center sills. A few rivets are driven in the hopper sheets to hold the body to the center sills, and the heads corrode or wear off, allowing the rivets to pull through the sheets. This results in the whole strain being thrown on the body bolsters, which are usually of a wide single plate type, with result that they are unable to stand up under the strain. The sills start moving back and forth under the car which soon gets in such condition that permanent or thorough repairs become a rather expensive operation. These conditions must be overcome as far as possible when car receives heavy repairs, if it is expected to continue the car in service. The sides and ends of steel equipment should be properly reinforced to prevent bulging or buckling. Doors, and door equipment and appliances should be kept in proper working order to facilitate unloading. Care should be taken in repairing trucks of all cars to provide proper side bearing clearance, and to see that air brakes and running gears are kept in good condition.

A well defined program of reinforcement should be outlined and put into practice on all roads. The cost of such additions and betterments is usually insignificant when the future life and productive service of the car is considered. Money appropriated for such features is a good, sound investment, when judiciously used, and should pay large dividends. Many roads make the mistake of repairing their older equipment in kind as they do not have exacting conditions on their line. Such equipment should either be reinforced or kept on their own line and not offered in interchange, when there is a possibility of it getting out into the large industrial centers and into heavy tonnage trains, when it is almost an impossibility to keep it off the repair tracks. This places an unnecessary burden of expense on both the owner and the handling line.

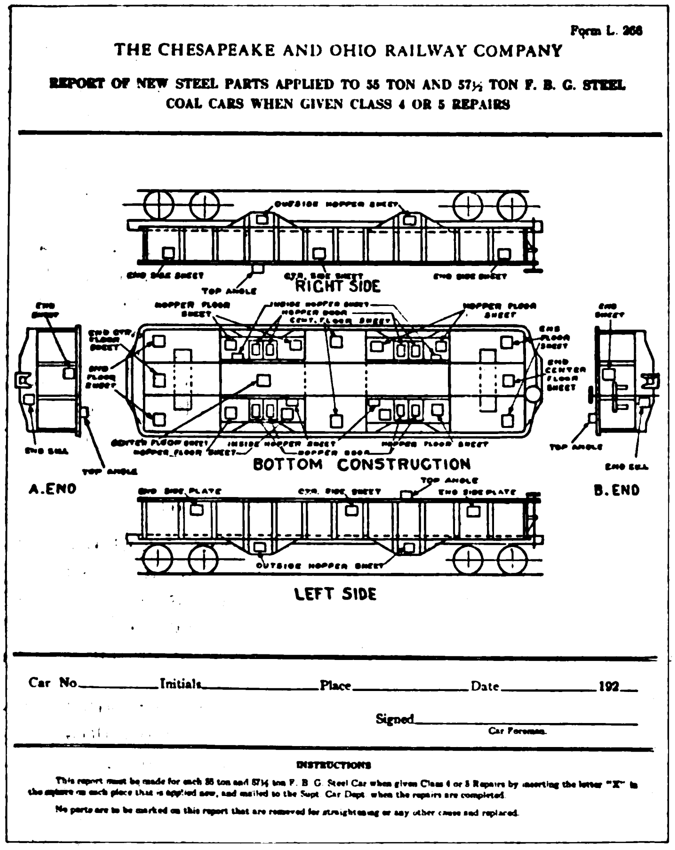
As cars come into the shop for general repairs, a careful inspection should be made; and, if a car has not deteriorated to the extent that it is felt advisable to scrap it, it should be repaired in accordance with a well defined reinforcement program, as outlined. Otherwise, if this is not done, after considerable money has been spent on the car it will again come back to the shop track.

Manner of handling work

A meeting of general, district and divisional car department officers is called three or four months before the close of the year, and the shopping schedule thoroughly dis-

cussed. A chart, previously prepared, showing the cars due for classified repairs or to be rebuilt the following year, is carefully considered and the cars are allotted to each shop represented, commensurate with its force and facilities. All cars in the same series are rarely allotted to one shop, but to at least two shops on opposite ends of the road. The cars to be rebuilt are selected by their general condition, the age being an important factor in determining just what parts of the cars are due for renewal. Past experience, tests, and service conditions and requirements under which steel car equipment operates, have demonstrated that floor and hopper sheets should be renewed every 10 or 12 years, while the side and end sheets will run for approximately 16 years before requiring renewal, if 1/4-in. thick. A definite program of reinforcement is outlined and closely followed.

At least 90 days is allowed in advance of starting on the



Form L. 268

THE CHESAPEAKE AND OHIO RAILWAY COMPANY

REPORT OF NEW STEEL PARTS APPLIED TO 55 TON AND 57½ TON F. B. G. STEEL COAL CARS WHEN GIVEN CLASS 4 OR 5 REPAIRS

Car No._______ Initials_______ Place_______ Date_______ 192__

Signed__________
Car Foreman.

INSTRUCTIONS

This report must be made for each 55 ton and 57½ ton F. B. G. Steel Car when given Class 4 or 5 Repairs by inserting the letter "X" in the square on each piece that is applied new, and mailed to the Supt. Car Dept. when the repairs are completed.

No parts are to be marked on this report that are removed for straightening or any other cause and replaced.

Form on which a record is kept of the new steel parts applied to each car

repair program to enable the purchasing and stores departments to purchase and deliver materials required; so, immediately following the allotment of cars to be rebuilt, each shop participating in the repair schedule places a requisition for 50 per cent of the material it will require, which should place this material on the ground in time to start with the year's program promptly. The other 50 per cent of the material is requisitioned in sufficient time so that it will be delivered in time to prevent any cessation of the work. If more than one series of cars are allotted to one shop, which is sometimes necessary, it is determined at the general meeting the order in which each series is to be routed through the shop and the material is ordered accordingly, the same advance information and consideration being given the stores department as mentioned above.

The entire schedule is laid down on a schedule and performance sheet, which permits the recording of starting and completion dates in proper sequence. The closest co-operation between the car and stores departments is absolutely necessary, not only to prevent any shortage of materials but also to avoid any surplus material being left on hand when the program is finished.

Classified repairs of steel cars

Cars in the same series are placed on bonded tracks equipped with electric rivet burning apparatus consisting of the following:

A generator supplying direct current not to exceed 80 volts, with 450 to 500 amperes for each cutting unit employed, located as near to cutting tracks as possible to prevent voltage drop.

Lead wires from generator to cutting stations of sufficient area to prevent excessive loss of watts.

A permanent scaffold six feet high and two feet wide, extending the entire length, and on both sides, of the burning tracks, the frame work of which is used for carrying the supply wires and having plug-in switches every 40 feet.

A rivet burning tool consisting of a graphite stick, held by a handle, of sufficient area to prevent excessive temperature resulting from heavy amperes carried.

A specially constructed mask to protect the operator's eyes and face from violet ray.

Cars placed on bonded tracks are inspected by a competent inspector or gang foreman. All sheets to be removed and replaced with new are marked with yellow crayon. All sheets and other parts to be removed, repaired and replaced are market with red crayon. All rivets not in sheets and other parts marked for removal, but necessary to be burned from draft lugs, center braces, door fastenings, etc., are also marked by the inspector.

Marked rivets, and rivets in sheets and other parts to be removed, are burned by placing the electric torch on the head or button of the rivet, depressing the head without injury to the sheets, stakes, or other parts that are to remain in the car. One operator burns out an average of 1,500 rivets each eight hours, and same operator cuts scrap sheets in shape for loading out as scrap; classification "Steel cars cut for shears." This operator is followed by an operator with a nine-inch pneumatic hammer, who backs out an average of 1,800 rivets each eight hours.

The major portion of the work done by electric burning and back-out rivet gangs is done on the second and third shifts, one burner and one back-out man forming a unit; but this operation can be extended over the three shifts or all be done on the first shift, depending on the track space and output desired.

When rivets are backed out the sheets are dropped, and the following day all scrap is picked up by a locomotive crane, equipped with a magnet, and loaded directly into cars to apply on a scrap sales order previously secured by the purchasing department. This eliminates unnecessary handling and the necessity of providing storage space to accumulate this class of scrap while awaiting sale. Parts to be repaired and replaced are pooled at the straightening shop, which is equipped with a furnace, a face plate, presses and necessary tools to restore parts to original shape. Nothing then remains but the skeleton car which is moved to the heavy repair tracks and the work proceeds from there as follows:

The second operation is performed by gang No. 2, or the truck gang. The cars are jacked up and placed on tripods, the trucks dismantled, and all broken or defective parts removed. This gang repairs all trucks and lets cars down on the trucks at the proper stage in the progress of the schedule. All arch bars are removed and taken to the smith shop where they are annealed and reset, by which process any crack or fracture is easily detected.

The dismantling gang, or gang No. 3, follows and backs out all rivits that cannot be taken out on the burner track, drops all couplers, draft gears, cylinders, reservoirs, bolster tie plates, space blocks, center plates, draft castings, and any other parts to be removed from the car.

Following the dismantling gang, the straightening gang, No. 4, straightens all parts that are to remain in the car, and prepares the car for the fitters.

The first fitters, or gang No. 5, follow and fit up all underframe work, end sills, tie plates, splice plates, space blocks, corner posts, sub-side sills, center plates, etc. Gang No. 6, the first reaming gang, reams the underframe, end sills, and all work fitted up by the first fitters, and makes the car ready for the first riveters.

The first riveters, gang No. 7, follow and drive all rivets under the car body and all rivets that must be driven before the car is fitted with side or floor sheets.

When entire sides are renewed, the side sheets, stakes, top and bottom angles are riveted up on the bench in jigs by gang No. 8, or the bench gang, and hung complete with locomotive crane by the 9th or second fitting gang. Gang No. 9, or the second fitters, working with an electric crane truck or locomotive crane, fit up the body of the car, hanging with special fitting up bolts, sides complete, side and end sheets or floor, hopper and cross ridge sheets, side and end posts; top and bottom, side and end rails, tie braces, side knee braces, etc. Gang No. 10, or the second reamers, follow and ream the entire body and prepare for the body riveting gang.

Gang No. 11, the second or body riveters, then drive all rivets in the body of the car, grab irons, sill steps, brake shaft platform and brackets, door attachments, etc. One gang fits up all door locks ready for final or OK riveters.

Gang No. 12, or the coupler gang, works in at any time after the bottom of the car has been driven. This gang puts up all couplers, uncoupling levers, card boards, brake mast, brake rods, brake levers, center pins, lock doors, greases center plates and side bearings, lets the car down on trucks, gages couplers and adjusts side bearing clearance.

Gang No. 13, OK riveters, works in one gang, driving all rivets in door locks, front carrier irons, and any rivets overlooked by regular riveters or missed by reaming gang, and drives all rivets marked out by the inspector. This method insures that all the work is properly performed.

Acetylene burners work in one or two gangs of one car repairer and one helper each, cutting out any rivets necessary to leave in on the burning track, cutting out bolster web plates for center sill splice plates, and any other work necessary to keep the regular gangs moving.

Laborers and helpers form a material delivery gang and work as follows: One man operates each electric truck engaged in the distribution and delivery of material, and, with two or more men, delivers to the car and truck all sheets, posts, rails, truck frames, wheels, spring planks, bolsters, and any other heavy materials. They also handle all couplers, arch bars, truck side frames, and other material, to and from the smith shop. One man keeps the rivet heating furnaces in repair and looks after the oil supply for rivet furnaces and heating torches. One or two men deliver to the cars and trucks all light materials such as grab irons, card board, brake mast and platform, ratchet wheels, brake hangers, brake levers, brake hanger rods, bottom connections, journal boxes, lids, brass and wedges, and bolts, nuts and rivets in quantities.

Located convenient to shop tracks are sufficient material racks with bins in which are kept short bolts, nuts, washers, cotters, clevises, knuckle pins and locks, brake pins, nut locks and grip nuts, and other small materials which are used in small quantities. One man takes care of these racks, replenishing the stock daily, and he also picks up any usable material left on the ground by carmen, returning it to the proper bin in the nearest rack. A standard list of material to be carried in each rack is posted, and each forenoon the attendant makes a check of the material on hand in these racks, and any shortage is ordered at one time and replaced in proper bins. This keeps a stock of such material on hand and convenient for the carmen's use at all times, thus eliminating the probability of waiting for the delivery gang or of hunting up the foreman for an order to the store room.

When cars are ready to paint they are moved to the shipping track where the air brake men, two car repairers and one apprentice repair and put in first class condition train lines, brake cylinders, and reservoirs; applying triple, release and retainer valves, angle and cut out cocks, hose and dirt collectors, which are cleaned and repaired in accordance with A.R.A. Rules governing the Maintenance of Brake, Train and Air Signal Equipment; connect, test and adjust brakes. Train lines, hose and all connections are given soap suds test; brake cylinders are given leakage test by gage; and triple valves are cleaned, repaired and tested on a standard test rack.

The cars are painted on the shipping track with a paint spray, working from a push car running on the service track along side of the car. On this push car are carried all supplies and materials required to coat the setting. When the paint is dry the stencilling is done from a scaffold erected on a push car, on which all supplies and stencils, made in panels, are carried. The painter moves himself on this push car by taking hold of the side of the car and pulling the scaffold and push car with him to the desired location.

Final inspection is made of cars on the shipping track, and any work marked out by inspector is corrected, if possible, before the painter has left the car. Cars are then reported ready to be pulled and weighed.

An individual car record of sheets removed is kept on special forms, as shown in the illustration. These forms are filed numerically and the record is available at all times in the general office to determine the general condition of an individual car of the series.

Classified repairs to box cars

After cars in the same series are spotted and properly spaced, they are carefully inspected by the gang foreman, accompanied by the stock clerk, and all parts to be renewed or repaired are so marked, and check made of material available, and necessary action taken to have all material on the ground when required.

Gang No. 1, or the truck gang, jacks up all cars in the setting, runs out the trucks and lets the cars down on trestles or tripods in a safe manner, after which it dismantles the truck, removing all defective or broken parts. All arch bars are removed and taken to the smith shop where they are annealed and reset. This gang is so regulated that trucks are rebuilt when the car is ready to let down.

Following the truck gang, the stripping gang, or gang No. 2, consisting of two car repairers and sufficient laborers to keep the yard clean of scrap lumber, removes all trimmings, drop couplers and draft gears, defective or broken siding, flooring, lining and roofing.

The sill and frame gang, gang No. 3, follows and removes all defective or broken sills, posts, braces, side plates and end plates, belt rails, purlines, ridge poles and carlines, replacing them with new, squaring the car, tightening all sill and plate rods, trussing car, repairing and replacing couplers and draft gear, and letting car down on truck. This gang also removes, repairs and replaces body bolsters and draft arms.

The fourth operation is performed by the sliding gang, which applies all siding, side and end fascia, door tracks and top corner bands. The roofing gang, gang No. 5, follows and patches or applies roofs complete with running boards. The flooring gang, gang No. 6, patches or applies new floor complete. This gang is followed by gang No. 7.

the inside or lining gang, applying or patching all end and side lining and grain strips.

Gang No. 8, or the safety appliance gang, follows and applies all grab irons, sill steps, lift levers, center corner bands, brake shafts, front and back door stops, and hangs the doors. The doors are repaired or made new and trimmed in the door shop and delivered to the car ready to hang.

The steel gang, gang No. 9, consisting of two or more car repairers and apprentices, is what may be termed a floating gang, doing any steel work required, such as straightening riveting, etc., and works closely in touch with the sill and frame gang. The acetylene gang, consisting of one car repairer and one apprentice, works wherever needed and has no regular routing to follow.

The air brake men are the last to finish their work of repairing and putting up train lines, brake cylinders, reservoirs and triple valves, and connecting, testing and adjusting brakes. Triple valves are repaired, cleaned and tested on a standard test rack.

Where the shipping track is provided the cars are pulled from the shop track and spotted on the shipping track, where painters and air brake men perform their portion of the work, similar to the same operation on cars of steel construction.

The painters follow closely behind all wood working gangs, painting sills, belt rails and plates ahead of siding, roofing and flooring gang, whom they follow closely. Cars are all painted and stencilled when the air brakes are tested. After a final inspection the cars are ready to pull. The yardmaster is so notified; and a list is furnished him of the cars to be set in after OK'd cars are pulled from the tracks.

The working of cars in the same series is an advantage to all departments. The siding, roofing, flooring and lining is cut to length in the mill. The same material, bolts, castings and timber are used throughout the entire setting. The painter need carry only one set of stencils for the series of cars being repaired.

The number of men in the various gangs, on both steel and wood cars, is governed by the amount of room on shop tracks, facilities, the output desired, the class of equipment undergoing repairs, and the amount and character of repairs, reinforcements, etc., necessary and applicable to the majority of the cars in the setting.

Requirements

What is needed more than anything else is a systematic program for making heavy repairs to freight cars so that a certain percentage of the equipment will be given such repairs each year, this percentage to be based on the number of years a car can safely run between heavy repairs. Locomotives are shopped on a mileage basis. Why not establish a reasonable and scientific basis upon which to shop freight cars and then see that it is lived up to. This will keep the equipment in prime condition, at a minimum of expense, after a systematic program has been well established.

Shops should be provided at points where heavy repair car work is performed. Overhead crane service is desirable and by proper arrangement eliminates the necessity for material or service trucks between the working tracks. Small wall of jib cranes should be installed for handling yoke riveters, etc. The money expended for shops will repay the investment many times over in a few years.

There is a large field for consideration and planning, when designing new shops, to provide proper tracks and facilities, which will co-ordinate with production systems and schedules best adapted to produce maximum output and minimum cost.

Decisions of the Arbitration Committee

(The Arbitration Committee of the A.R.A. Mechanical Division is called upon to render decisions on a large number of questions and controversies which are submitted from time to time. As these matters are of interest not only to railroad officers but also to car inspectors and others, the Railway Mechanical Engineer will print abstracts of decisions as rendered.)

Another case under Rule 32

C., M. & St. P. car No. 9403 received some damage while in possession of the N. Y. C. & St. Louis which it was claimed occurred in the ordinary switching service and disposition was requested from the owners in accordance with Rule 120. The car owner claimed that the damage was due to the handling line responsibility. In making its contentions, the car owner stated that it had received a letter from the handling line which stated, among other things, that it was not the practice to ride cars in Conneaut Yards where the accident occurred. The car owner further contended that the damage exceeded that specified in the footnote to Rule 43. The handling line contended in its statement that it had received the car in question from the N. Y. C. at Buffalo, N. Y., at which time an inspection was made which revealed a number of defects. In view of these defects the car was billed home to the owner at Chicago. It was while the car was en route home that it was damaged in switching service which caused eight sills to break on the car. As the car was not derailed, roughly handled or damaged in any other manner outlined in Rule 32, the handling line felt justified in requesting a settlement in accordance with Rule 120.

The Arbitration Committee rendered the following decision "The car being handled without rider protection, the handling line is responsible as per Rule 32, Section D, Item 4. See Arbitration Decisions Nos. 1224 and 1331.

"In the event repairs are made, the car owner is responsible for that portion of the defects which are ordinarily the owner's responsibility and not associated with the delivering line defects, as provided in Rule 41."—*Case No. 1335, Chicago, Milwaukee & St. Paul vs. New York, Chicago & St. Louis.*

Wheels remounted on Standard A. R. A. axles with wheel seats in excess of standard diameter

The Chicago, Burlington & Quincy included in its bill to the Southern Pacific a charge amounting to $36.06 for repairs to S. P. car No. 62342 at Alliance, Nebr., November 30, 1921. The bill in question bore no date, but represented the account as of November, 1922, and contained charges for repairs made on November 30, 1922. The car owner contended that revisions of Paragraph 2, Section A, Interchange Rule No. 91 of the 1921 Code, had been violated. The C., B. & Q. also included in this bill a charge for wheels and an axle changed under S. P. car No. 24846 at Alliance, November 17, 1922, on account of one wheel being tread worn and the other having a large bore, at the same time scrapping the axle on account of large wheel seats. The car owner contended that the axle should have been credited at second-hand value. In defense of the first part of the agreed

statement of facts, the S. P. contended that the second paragraph of Section A, Rule 91, distinctly provides a time limit of one year within which charges for repairs are to be represented. With respect to car No. 24846, the S. P. contended that the wheel and axle record represented by the repairing line shows the diameter of the wheel seats for the axle removed to be 7⅛ in. This was ⅛ in. larger than the dimensions for the new axle as specified in the table in Rule 86. However, its interpretation of this table was that the diameters for the wheel seats and center are minimum, and that there should be no objection to slight variations which in themselves actually increase the strength of the axle. The C., B. & Q. contended in its statement that it had complied with both the letter and spirit of Rule 91 and that the bill was actually made and rendered in November, 1922, with the necessary delay required to add final entries and make recapitulations along with 500 other bills for the same month. With reference to the renewal of the wheel and axle under car No. 24846, the handling line claimed that an axle for the minimum limit of wheel seat prescribed by the table in Rule 86 is in effect scrap and that wheels fitted to such an axle are likewise scrap regardless of whether the wheel seat dimension is great or small.

The Arbitration Committee rendered the following decision "With reference to the time limit for rendering a bill, Arbitration Decision No. 1228 is parallel. The contention of the C., B. & Q. is sustained.

"The general situation is such as to warrant the practice of using A.R.A. standard axles with wheel seats not more than ⅛ in. in excess of standard diameter for remounting second-hand wheels, in order to avoid scrapping good wheels. The 1924 Code of Rules will be modified to make this clear. Therefore, the contention of the C., B. & Q. is not sustained."—*Case No.* 1333, *Southern Pacific vs. Chicago, Burlington & Quincy.*

Credit for wheels removed because loose on the axle

On March 11, 1922, the Atlanta, Birmingham & Atlantic exchanged wheels under Illinois Central car No. 131255 showing under the "Why Made" column one wheel OK, one wheel loose on the axle and scrap on which a charge was made against the car owner for one pair of second-hand wheels applied, less one second-hand and one scrap wheel removed, or $3.60, it being claimed by the repairing line that the wheel scrapped was unfit for further use owing to having been removed from a standard axle. The I. C. maintained that both wheels removed should have been considered under the existing condemning limits as second-hand inasmuch as the A.R.A. rules make no provision for the scrapping of wheels for such causes as claimed by the repairing line.

In rendering its decision, the Arbitration Committee stated that "If the loose wheel was unfit for remounting on a standard axle with a wheel seat not more than ⅛ in. in excess of the standard diameter, it should be credited as scrap. If it could be so remounted, it should be credited as second-hand.—*Case No.* 1334, *Illinois Central vs. Atlanta, Birmingham & Atlantic.*

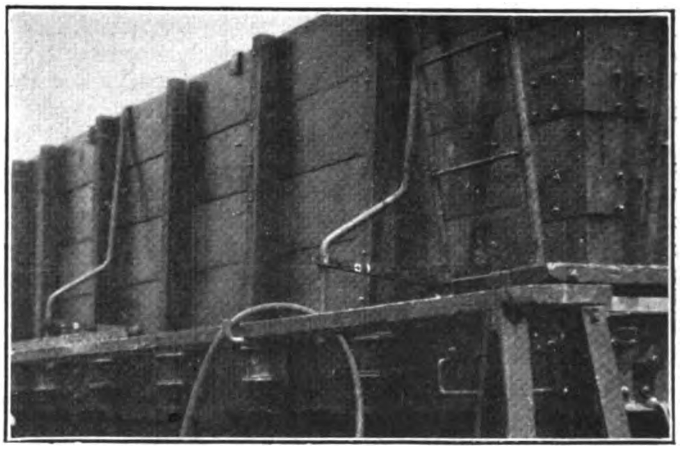
Car without rider protection damaged in switching service

On June 20, 1923, Canadian National car No. 610862 was damaged while being switched at South Chicago and was reported by the Chicago, Rock Island & Pacific showing an estimated cost for labor of $185 and material of $200, making the total $385. The damage occurred when two cars of coal, without rider protection, ran into C. N. car No. 610862, breaking it in two at the middle. The handling line contended that the responsibility for the damage to the car did not come under Rule 32, Section D, Item 4, nor the footnote to Rule No. 43 for two reasons: first, that only five sills were broken new which was evidenced by the records which show that when the car returned through interchange to the handling line, one side sill and two intermediate sills were broken, were old or decayed and were broken prior to the time the car was broken in two in switching service. Second, the car was not derailed, cornered or sideswiped. The handling line further claimed that rider protection was not necessary as the accident occurred in a level yard while the cars were being switched at ordinary safe speed. It was the contention of the car owner that the handling line was responsible under Rule 32, Section D, Item 4, and that the car should be handled under Rule 112, as no rider protection was provided.

The Arbitration Committee in rendering its decision stated that "The damage exceeded that shown in the footnote to Rule 43 and as car was being handled without rider protection, the handling line is responsible as per Rule 32, Section D, Item 4."—*Case No.* 1336, *Chicago, Rock Island & Pacific vs. Canadian National.*

A convenient type of portable scaffolding

An interesting feature of the car building contest recently held by the car department of the Delaware & Hudson at Carbondale, Pa., was the numerous kinks and unique practices used by the three contesting teams. The Oneonta team, the victors in the contest, were



Scaffolding arrangement used by the Oneonta team, victors in the D. & H. car repair contest

especially well equipped with various improved tools and devices for efficiently performing the work. One of these devices is the portable scaffolding shown in the illustration.

The planks for the floor of the scaffolding are placed on a bracket made of round bar iron about 1¼ in. in diameter. The bar is bent so as to hook over the side of the car and extend down to form a support for the plank, as shown in the illustration. It is held in position against the side of the car by means of a brace made of ⅜ in. by 1¼ in. wrought steel bar. The brace is made in two pieces, bent to the same shape, so as to form a clamp for the round bar at one end and a base at the other. The two pieces are then placed back to back, clamping the round bar as shown in the illustration, and held securely by three ½-in. bolts.

Master Painters meet at St. Paul

Methods of securing satisfactory painting results with the least expenditure of time and money are discussed

THE fourth annual meeting of the Equipment Painting Section of the Mechanical Division, American Railway Association, was held at St. Paul, Minn., the week of September 14, 135 master painters representing railroads in all parts of the country being in attendance. Much of the discussion centered on methods of painting railway equipment which would produce satisfactory results at the least cost and at the same time hold equipment out of service as short a time as possible while in the paint shop. Considerable emphasis was placed on methods of testing paints and several engineers of tests from various railroads discussed the problem of painting from this angle. Steps were taken to place railroad testing of paints on a more scientific basis.

The master painters were welcomed to St. Paul on behalf of the railroads by E. F. Flynn, assistant to the vice-president of the Great Northern, who made an inspiring address on the improved relations between American employers and employees which has taken place in recent years. He pointed out the dependence of each on the other and said that only by mutual helpfulness can American ideals and the present high standard of living be maintained.

During the meeting tribute was paid to Secretary V. R. Hawthorne when the members presented him with a solid gold railroad watch in token of appreciation for his faithful services in the interests of the Equipment Painting Section and its predecessor, the Master Car and Locomotive Painters' Association.

F. W. Bowers (Erie)
Chairman

A. E. Green (C. & N. W.)
First vice-chairman

James Gratton (B. R. & P.)
Second vice-chairman

Election of officers

The following officers were elected for the year 1926: Chairman, A. E. Green, foreman painter, Chicago & North Western, Chicago; first vice-chairman, James Gratton, general foreman painter, Buffalo, Rochester & Pittsburgh, Dubois, Pa.; second vice-chairman, F. E. Long, foreman painter, Chicago, Burlington & Quincy, Aurora, Ill. According to the regulations of the Section, the last two past chairmen automatically become members of the Committee of Direction, which together with the three above make the Committee of Direction of the Equipment Painting Section as follows: H. Hongeveld, master painter, Atlantic Coast Line, Waycross, Ga.; B. E. Miller, master painter, Delaware, Lackawanna & Western, Kingsland, N. J.; H. C. Allehoff, foreman painter, Oregon-Washington Railroad & Navigation Company, Portland, Ore.; L. B. Jensen, general foreman, passenger department, Chicago, Milwaukee & St. Paul, Milwaukee, Wis.; D. C. Sherwood, foreman painter, New York Central, West Albany, N. Y.; J. McCarthy, foreman painter, Canadian National, Montreal, Que.; W. Mollendorf, foreman painter, Illinois Central, Chicago; G. H. Lehnen, foreman painter, Chicago & Eastern Illinois, Danville, Ill.; A. H. F. Phillips, foreman painter, New York, Ontario & Western, Middletown, N. Y.; Marceau Thierry, foreman paint shop, Norfolk & Western, Roanoke, Va.; J. N. Voerge, general master painter, Canadian Pacific, Montreal, Que.; and J. McDowell, foreman painter, Chicago, Rock Island & Pacific, Chicago.

Abstracts of several of the papers are given below. The papers dealing with testing will appear in a later issue.

Apprentice systems

By J. W. Gibbons

General master painter, Atchison, Topeka & Santa Fe, Topeka, Kan.

The writer has always advocated that for the first three years students for all crafts could and should have the same studies. The fourth year should be specialized along the lines of the craft he is learning. The painter apprentice should be taught free hand drawing, designing and elementary lessons in the chemistry of oils and pigments and their relative protective qualities. He should be encouraged to read well chosen text books containing

the fundamental principles of the painting craft. And as this may be considered the iron and steel age, he should be taught the elements that enter into their destruction and the best means of preserving them.

In addition to the school, the Santa Fe has shop instructors whose duty it is to teach the boys the practical side of the application of paint and designing of letters and ornamentation, as well as to emphasize the fact that the first and most essential reason for painting is preservation of the surface and that ornamentation is only a secondary consideration. It is up to the foremen and apprentice instructors to realize their responsibility in handling the apprentice assigned to them. We take the place of the teacher in educating the youth of today so he will be the craftsman of tomorrow. We teach him to breathe a soul into his work, in fact, the future of the boy is in our hands. The habits he forms as an apprentice will remain with him when he becomes a mechanic. If he learns to do work neatly and correctly as an apprentice it will be no trouble to do it when he graduates. If he gets the correct view of the relation a workman has to his foremen and instructors, he will retain it. If we treat him gruffly and instruct him grudgingly, he will assume that attitude toward us and our work. Worse than that, he will take it for granted that we are representatives of the company that employs us and he will become a pessimist as to the good faith in the promises of fair treatment made to all employees by higher officers. We can make the boy a good, loyal mechanic, or we can make of him an indifferent, careless workman, whose mind is in rebellion against all authority. A boy, unconsciously, is affected by examples of those around him, especially those who have authority over him.

Supervisors should always remember that it is their duty, not only to teach the boy a trade, but to build character, to assist the boy in acquiring a personality. Give him faith in humanity; make him a thorough craftsman.

Shop construction committee discusses mechanical painting

It is a well known fact that a shop of modern construction and equipment is a great help towards economy and efficiency. If a shop and its equipment are ancient, then economy and efficiency are crippled to some extent.

We understand that our railroads have not gone very deeply into the mechanical painting of passenger car bodies. We who have used the mechanical system of painting know of the many objectionable features when used inside of the shop buildings. The fumes and mist that arise from the operation endanger the health of the operators and those who are required to be in the immediate locality and the mist settles on other equipment. If mechanical painting is used to any extent, the work should be confined to a certain section of the shop provided with booths or screens to protect other equipment. This section should be ventilated with a vacuum system, so that the fumes and mist can be removed through the ventilators.

The mechanical painting of removable and small parts is being done by the use of different kinds of devices, and a great deal of thought, time and money have been expended by various concerns in the manufacture and improvement of mechanical painting devices. A number of railroads have made or are making trial applications with mechanical painting devices for locomotives and coaches with lacquers and different kinds of finishes. Pyroxylin finishes are now produced by a large number of manufacturers under many different trade names. About all of these materials are made on the general principle of a nitro-cellulose base dissolved in various liquids of a highly volatile and inflammable nature. The fire hazards involved are very great and great care should be taken in equipping the place or building with fire protection, where mechanical painting is done.

(The committee's recommendations relative to the design of the paint, cabinet and pattern shops, and also removing paint by the sand blast process, are the same as those made by the Committee on the Design of Shops and Engine Terminals at the 1925 annual meeting of the Mechanical Division, A.R.A. An abstract of this report was published in the July, 1925, *Railway Mechanical Engineer*, page 412.—Editor.)

The report was signed by the chairman A. H. F. Phillips, N. Y., O. & W.; O. S. Minnick, W. M.; C. E. Ream, Penn.; J. T. MacLean, B. & M., and W. F. James, A. C. L.

Maintenance and care of paint and varnish at terminals

Freight and passenger locomotives should be cleaned before every trip. Where a washing machine is available, the locomotive should be placed on a wash track and the drivers, trucks, frames, spring rigging and tender trucks washed. These parts should then be wiped with kerosene. Jackets, cabs and tenders should be wiped with waste saturated with renovator, followed by dry wiping with waste. The front end should receive a suitable front end paint, and where the paint shows a tendency to scale, it should be removed and cleaned to the bare iron and repainted before the engine is placed in service.

Passenger locomotives should be repainted every nine months. Freight locomotives every twelve months and switching locomotives every fifteen months. The painting of locomotives should be done in stalls partitioned off for this purpose which should always be properly heated, ventilated and lighted.

Exterior cleaning of passenger cars

The exterior of passenger cars are to be washed daily with cold water before the cars leave the terminals. The exterior of cars used in first class trains and main line service should be washed with a solution of oxalic acid every 30 days or when the condition of the cars demand it. After applying the acid and all grease and dirt has been loosened, the acid and dirt should be washed off with cold water. Care should be taken that no acid and dirt remains on the body of the car.

The solution of oxalic acid should be 20 lb. dissolved in 50 gal. of hot water. It must be thoroughly dissolved and allowed to cool and applied cold.

The bodies of passenger cars should be renovated after each periodical washing, as this will destroy the effectiveness of the acid and stop it from working into the open joints, window sash brads and open sheathing. To apply the renovator use a handful of waste moistened with renovator and after it has been applied, care should be taken to see that the surface is thoroughly wiped dry and clean with clean waste. First class cars should be washed with oxalic acid and renovated every 60 days. New and newly painted cars operating in first class trains and main line service, should not be washed until a period of 20 days has elapsed. Trucks should be sprayed or wiped with distillate oil and washed with soap and water. All washing compounds and soda solutions must be avoided, as these compounds will destroy the varnish and paint.

Interior cleaning of passenger cars

All passenger cars should be blown with compressed air and all dust removed, before washing the head lining, wall pipes, and seat arms. They should be washed with a

solution of soap and water, then rinsed and dried with a chamois skin. The solution of washing material should be put in one pint of diluted vegetable oil soap to a bucket of water. Floors should be mopped and care taken that not too much water remains on the floor, causing the floor to become water soaked, which is injurious to the under frames of passenger cars. Toilets, baggage and express car floors should be washed with a solution of one-half pint of disinfectant to 12 quarts of water. Vestibules should be washed with soap and water and dried with a chamois skin. The interior of the cars should be gone over with a suitable furniture polish or renovator when the varnish becomes dry and dull looking. This work should be done by experienced men.

Painting of passenger cars

Terminal painting—When the cars present a bad appearance they should be held out of service and have the parts repainted that demand it, at the coach yards. The painting of the roof, steps, trucks, vestibules, sash, head lining, seat arms, foot rests and guards, pipes, pedestal and floors, should be done under the supervision of experienced employees.

A great many railroads have applied lacquer to passenger cars for test purposes and your committee recommends that all such cars be washed with a solution of vegetable oil soap and rubbed thoroughly dry after each period of 30 days. The secret of success in the cleaning of this equipment is the thorough rubbing after it is cleaned, as this brings about a high gloss that is much desired.

The report was signed by G. Schwantes, chairman, C., M. & St. P.; J. J. McNamara, B. & O.; J. H. Whittington, C. & A.; J. McCarthy, C. N., and H. E. Brill, A., T. & S. F.

Report of committee on standards—Cars and locomotives

What success, if any, has been obtained to prevent paint peeling from galvanized iron car roofs?—It is the consensus of opinion of the committee that galvanized iron, when new, should only receive one coat of company standard paint for appearance sake. The result of tests shows that asbestos fibre cements have adhered better than the ordinary carbon blacks or oxide paints, and have proved more permanent.

The most practical and economical method of bringing up interiors of steel passenger coaches for graining or coloring.

First day—Sand blast and apply railroad company's standard steel car primer.
Second day—Stand to dry.
Third day—Apply coat of steel car surfacing.
Fourth day—Putty and knife where necessary.
Fifth day—Sandpaper and apply first coat of railroad standard enamel.
Sixth day—Stand to dry.
Seventh day—Apply finishing coat of enamel.
Eighth day—Apply standard ornaments, striping and necessary notices.

In cases where cars are to be grained, two coats of ground color should be applied, allowing 24 hours for drying between each coat; the first coat of ground color to be applied on the fifth day, instead of enamel. Then grain and apply the first coat of varnish. Apply the necessary ornaments and notices, followed by two coats of varnish.

Where rub finish is required, 48 hours should be allowed after the last coat of varnish. Rubbing should be done in accordance with railroad shop practice.

The most practical and economical method of bringing up the exterior of steel passenger coaches—Where finish and appearance would be acceptable to the railroad company officers, your committee would recommend the following system, as it would provide ample protection:

First day—Sand blast and prime with approved steel car primer.
Second day—Stand to dry.
Third day—Apply coat of steel car surfacing.
Fourth day—Putty and knife where necessary.
Fifth day—Sandpaper and apply coat of standard color semi-gloss and of sufficient covering qualities that one coat will cover.
Sixth day—Ornament and letter. If the shade of body color used requires two coats, the second coat of color can be applied in the morning and lettered on in the afternoon. Follow with two or three coats, in accordance with shop practice, of coach finishing varnish to be applied.

What is the most economical and practical material for passenger car headlinings?—This committee recommends from a maintenance standpoint agasote, panelyte or similar material, as the most economical and practical material for passenger car headlining.

Standard for painting of passenger and freight locomotive cabs, domes and tenders—This committee recommends the following system as a standard for painting of passenger and freight locomotive cabs, domes and tenders:

1—Sand blast should be used for removing all old paint and scale from the metal.
2—The primer and surfacers used should be all black in color. The reason for recommending black undercoatings is that one coat of black locomotive finish will cover more solidly, and abrasions will not show as readily as with lighter undercoatings.
3—After lettering, apply one coat of finishing varnish on freight and two coats on passenger locomotives. Both black locomotive varnish and finishing varnish should be resistant to either hot or cold water.

The report was signed by G. H. Lehnen, chairman, C. & E. I.; J. N. Voerge, C. P.; A. E. Green, C. & N. W.; D. C. Sherwood, N. Y. C.; K. J. Johnson, N., C. & St. L., and F. E. Long, C., B. & Q.

Painting of freight car equipment

A great majority of the new steel equipment is not being sand blasted before painting, causing the paint to peel in a short time. This committee considers it most important to sand blast equipment, whether new or old, before painting and then prime with an approved standard metal protector. A primer made of chromate of lead has been found to be very durable. For open top cars, this primer can be followed with two coats of carbon black.

On steel box cars, after sand blasting and priming, apply two coats of oxide of iron, thinned to a brushing or spraying consistency with two-thirds boiled linseed oil, and one-third thinning oil. All steel underframes should be sand blasted and coated with a good metal primer, followed with at least one coat of standard body color. We do not consider it necessary to paint trucks other than new.

Steel or galvanized iron roofs, after being sand blasted, should be primed with the same material as the body, followed by two coats of the railroad company's standard roof paint. All stencilling should be done with white lead in oil, thinned to stencilling consistency, with boiled linseed oil. On new box cars, the interior of all steel plates, posts, braces, etc., should be painted with a good metal protector and one coat of oxide of iron applied. A good heavy red lead, or satisfactory metal protective paint should be applied on all new cars where metal overlaps, or is joined.

We recommend the following for new wooden equipment: All steel underframes should receive the same treatment as for steel cars. The outside of the sheathing, and all sides of roof boards and saddles, should be primed

with oxide of iron and boiled linseed oil before being applied to the car, after which two coats of oxide of iron should be applied, thinned to a brushing or spraying consistency with two-third boiled linseed oil and one-third thinning oil.

Roofs, if wood, should receive the same treatment as the body of the car. If metal, the same treatment should be given as on steel equipment. All stencilling should be done with white lead in oil, thinned to a stencilling consistency with boiled linseed oil. In the maintenance of old equipment, all new work should receive three coats and old work two coats of oxide of iron. Underframes on old equipment should receive one coat of standard body color. Roofs should receive two coats of railroad standard roof paint.

Owing to the necessity of getting this equipment into service with dispatch, we recommend that all painting be done by the mechanical method. While climatic conditions on certain railroads may require a slight change in the outer coatings, the committee believes that the above would be a good general practice.

The report was signed by the chairman D. C. Sherwood, N. Y. C.; Edward McDade, G., C. & S. F.; E. S. Butcher, F. W. & D. C.; C. O. Smith, B. & L. E.; H. C. Allehoff, O. W. R.R. & N. Co.

Applying corrugated steel ends to box cars

THERE are many car repair yards having considerable work to do in repairing box cars, that are not provided with adequate crane facilities to handle the work and it is a difficult job to apply corrugated steel ends without the assistance of a crane. One car shop, however, has been able to perform this work quite effectively by means of the trestle and derrick shown in Figs. 1 and

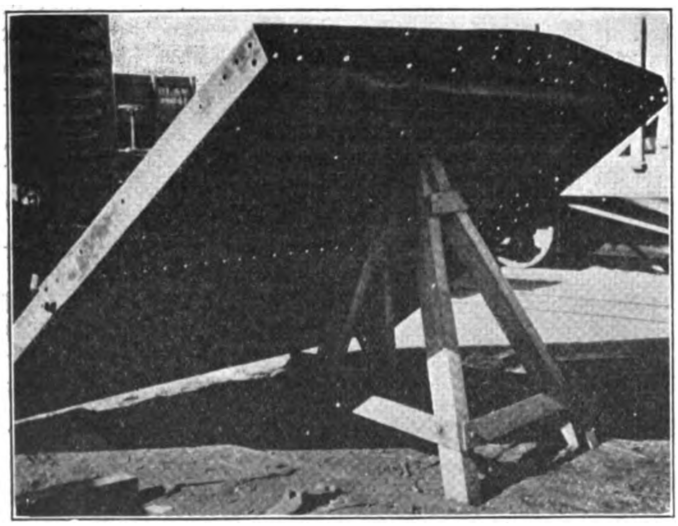


Fig. 1—The trestle holds the car end in such a position that the car repairman can work underneath

2, respectively. Referring to Fig. 1, the trestle is constructed with grooves in the top that fit the corrugations on the car end. The top is sloped so that the bottom of the car end rests on the ground and the top is elevated sufficiently so that a car repairman may work underneath.

Car ends are placed in position and applied by means of the derrick shown in Fig. 2. The derrick consists essentially of two timbers which form the legs and are braced by two cross-pieces. It is placed in position as shown in Fig. 2, and held by blocks and tackle, one block is secured to the top and the other to an adjacent car.

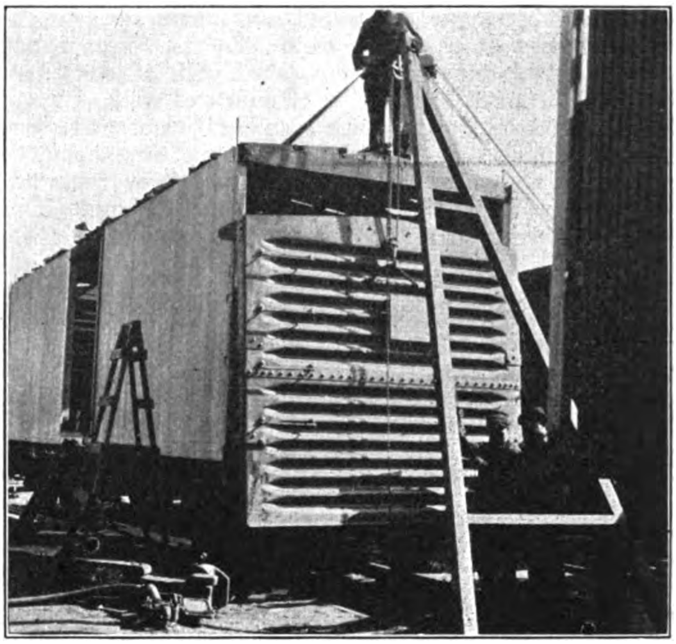

Fig. 2—Applying a corrugated steel end with a derrick and chain hoist

In this way the derrick may be adjusted to any height desired. The car end is then raised to position with a chain hoist.

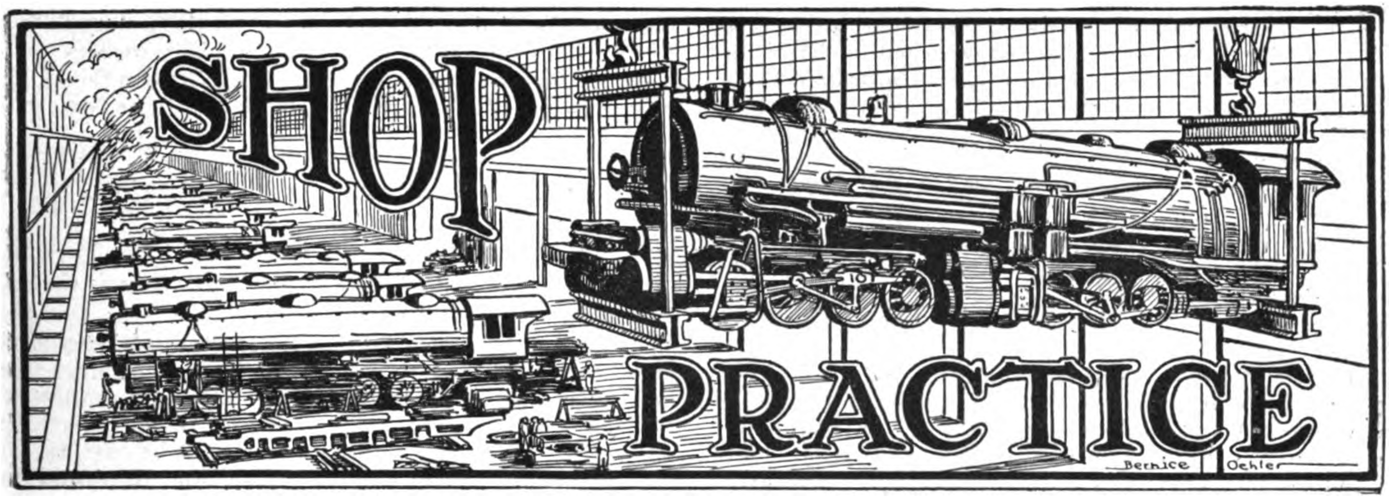
Perpetual examination of brasses*

DURING the past few months I have observed a practice which may be termed "perpetual" rather than "periodical" examination of brasses. The method appears the most logical of any I have studied and is bringing splendid results. A "hot box" out of the terminal coach yard is a rare occurrence.

Instead of examining the coaches in the yard when the journals are cool, an inspector of unquestioned ability is stationed at the terminal depot, where the journals can be examined immediately on arrival of the train when they are still at a running temperature. The inspector feels every journal, in addition to making a careful visual examination. When he finds a journal warmer than normal, he marks the box for examination, knowing there must be something which caused the excessive heat, not necessarily knowing what. This box is jacked up when the car reaches the coach yard, the trouble ascertained and the remedy applied.

There are a great many terminals, both passenger and freight, where this could be followed and a "perpetual" examination of brasses made which might make unnecessary the "periodical" examination. It would seem more dependable to determine conditions by actual running temperatures than by a "cold" examination, which will not disclose many defects, such as cracked linings, defective wedges, too old "dope," etc. A high running temperature does indicate one or more undesirable and possibly dangerous conditions.

*An extract from a paper by W. H. Davis, service engineer, Universal Packing & Service Company, Chicago, entitled "Practical lubrication of railway equipment," read December 1, 1924, before the Cleveland Steam Railway Club at Cleveland, Ohio.



Tool foremen meet at Chicago

Thirteenth annual convention best attended and most interesting recently held

THE thirteenth annual convention of the American Railway Tool Foremen's Association, held September 2 to 4 at the Hotel Sherman, Chicago, surpassed both in point of view of attendance and interest in the valuable reports and papers presented, any convention of this association held in recent years. The opening address was made by H. T. Bentley, general superintendent of motive power and machinery of the Chicago & North Western, who commented on the importance of the work of railway tool foremen and pointed out the opportunity which they have of saving money for the railroads by providing more efficient tools with which employees in shops and enginehouses can work. The tool foreman's responsibilities were discussed by G. T. Martin, assistant to the general superintendent of motive power of the Chicago, Milwaukee & St. Paul, and the proper machine equipment for toolrooms by C. A. Shaffer, general supervisor of shop machinery and tools of the Illinois Central. E. J. McKernan, general supervisor of tools of the Atchison, Topeka & Santa Fe, discussed "Economies possible by standardized small tools," and E. L. Woodward, western editor of the *Railway Mechanical Engineer*, read a paper entitled, "The importance of the toolroom to the railroads," emphasizing some ways in which the toolroom can be operated to help reduce shop and enginehouse costs. E. A. Hildebrandt, tool foreman of the Cleveland, Cincinnati, Chicago & St. Louis at Indianapolis, presented some pertinent remarks on "Co-operation." An abstract of the papers and reports presented at the convention will appear in this and subsequent issues of the *Railway Mechanical Engineer*.

Election of officers

The new officers of the association elected for 1926 are as follows: President, E. A. Hildebrandt, tool foreman, Cleveland, Cincinnati, Chicago & St. Louis, Indianapolis, Ind.; first vice-president, O. D. Kinsey, general supervisor of tools, Chicago, Milwaukee & St. Paul, Milwaukee, Wis.; second vice-president, E. L. Graeme, tool foreman, Delaware, Lackawanna & Western, Scranton, Pa.; third vice-president, W. R. McMilligan, tool foreman, Missouri-Kansas-Texas, Parsons, Kan. G. G. Macina, Chicago, Milwaukee & St. Paul, Chicago, was elected permanent secretary-treasurer of the association. The newly elected executive committee consists of E. C. Heingarten, (C. & N. W.), M. J. Harney, (N. Y., N. H. & H.), J. T. Sumner, (M. C.), L. C. Brown, (C. B. & Q.), and W. J. Hynes, (M. P.).

The tool foreman's responsibilities

By G. T. Martin

Assistant to general superintendent of motive power, Chicago, Milwaukee & St. Paul, Chicago

To obtain a practical demonstration of the tool foreman's responsibility, it is only necessary to be close to a job where a mechanic is trying to do a day's work, with a motor that will not function properly, or a reamer that fails to cut or perhaps an air gun that fails to do business. In cases of this kind, the tool foreman's responsibility is fully and clearly established in the mind of the man operating such tools. What he is saying about the tool foreman would, in my opinion, be too spicy to appear in print.

Conditions of this nature cannot generally be charged against the tool foreman because in my experience I never found a real tool man who would willingly allow tools in his cars to get in such condition. In a shop where poor tools are in evidence to any great extent, the responsibility for such conditions generally rests upon the local or general officers. Either they fail to secure a competent tool man who can remedy the situation, or they fail to furnish proper facilities whereby a competent man can accomplish this task.

Many conditions contribute to the responsibilities of the tool foreman. The railroads are still struggling through a period which has demanded the greatest courage and resourcefulness on the part of the executives to meet the demand made on them for handling the country's transportation, without having the power to establish or secure competent returns to cover the ever increasing expense of operation.

In 1923, the railroads of this country attained a record that has heretofore never been approached in the history of transportation. The service rendered measured by the number of tons of revenue freight moved one mile, showed an increase of sixty billion net ton-miles greater than was moved in 1916. In hauling this great volume of business, the net revenue obtained was something like seventy-eight million dollars less than that obtained for handling the transportation business on the railroads in 1916. The year 1924 and the first half of 1925 show a marked decrease in tonnage available, resulting in a greater necessity for added returns to overcome deficits in net earnings in the future.

I touch on this important subject to reflect, if I can, the necessity of every man in all branches of the service realizing his full responsibility, in order that each unit may develop the highest standard of efficiency.

As mechanical men, one of our important problems is to increase the output of shops, roundhouses and repair yards, in order to cut maintenance costs to the very minimum. In this respect, the tool foreman plays a very important part. Assuming the best possible facilities and maintenance forces comprising workmen carefully selected, well organized and properly supervised, it will then depend on an adequate supply of properly maintained tools if our repair costs are to be brought to a minimum. Without sufficient well kept tools, no shop can hope to maintain its share of responsibility in output.

The tool foreman's responsibility rests largely in his ability to organize, develop, perfect and promote the thought, plan, device or organization connected with the successful maintenance of an up-to-date, adequate tool supply. We know that often tool foremen are held responsible for the condition of tools which have long outlived their usefulness. Those of us who have had practical experience realize that the tool foreman is often held responsible for tools which apparently have not held up under the strain or speeds for which they were built, owing to improper heat treatment or carelessness in manufacturing. Often you are held responsible for damage to tools on account of excessive speeds of motors, presses or machines when using drills, taps, dies, reamers, cutters, etc., when in reality the responsibility in these matters rests to a large degree on the lack of co-operation shown the tool foreman when he has intelligently brought the subject to the attention of his superior officer.

To have good tools available at all times requires a definite skilled organization. In this day and age, no man can do all the work or assume all the responsibility. He must of necessity depend upon his associates who comprise his organization and keep before them the motto of this association—"Higher efficiency in the railway tool service."

Chas. E. Helm (C. M. & St. P.)
President

Machine equipment for the toolroom

By C. A. Shaffer

General supervisor of shop machinery and tools, Illinois Central, Chicago

In the apparent increasing tendency toward better and more complete shop machinery and other facilities for making repairs to locomotives and cars, the matter of suitable equipment for the maintenance of all tools with which that work must be done, should not be overlooked.

In the past, it is quite evident that due consideration has not been given to equipping the tool department to the best advantage for making and maintaining in first class condition such tools as may be required. This is true of many shops from the largest to the smallest, and, at the present time, when the importance of good tools is being generally recognized, it may not be amiss to discuss the question of toolroom machinery.

The tool department of any railroad shop should be adequate to maintain all tools used locally or under that shop's jurisdiction properly and economically, and in order to keep pace with improvements made in design, and the increased size of machinery and tools for handling modern locomotives, it is necessary that corresponding attention be given to the equipment for maintenance of such tools.

Obviously, it is impossible to work out a definite list of machinery and equipment which would be practicable to meet requirements for all shops because of the various methods used by different railroads for handling this work, also the kind and amount of work to be done and local conditions governing. Therefore, it would seem desirable to submit possibly three groups of equipment for consideration either separately or in combination of items from one or more groups as may be best suited to meet the requirements of individual cases.

Some of the larger railroads make it a practice to have centralized toolrooms, usually located at their main shops, where certain standardized tools are made for the entire railroad and shipped to the different points on requisition. These are generally known as manufacturing toolrooms.

and require somewhat greater and more diversified lots of equipment than the tool departments where only maintenance or reconditioning work is done.

However, the majority of railroads have tool departments at their main shops where all local tool maintenance and repairs are taken care of, and, possibly, some new work in emergency cases or for occasional replacements.

Group No. 1.—Equipment for general tool manufacturing and maintenance department

Item No.	Nominal size	Type and kind of machine	Special equipment or extra attachments
1	20-in. by 10-ft	Engine lathe	Taper attachment; 16-in. four jaw independent chuck.
2	18-in. by 8-ft	Engine lathe	Taper attachment; 14-in. four jaw independent chuck.
3	16-in. by 8-ft	Toolroom lathe	Taper attachment; draw-in attachment; universal relieving attachment and one universal, and independent chuck.
4	14-in. by 6-ft	Toolroom lathe	Taper attachment; draw-in attachment; universal relieving attachment and one universal, and independent chuck.

Miscellaneous

Air flow meters.
Air tool testers.
Scleroscope and other measuring or testing instruments.

In selecting a list of toolroom machinery, there are a number of important points to be considered, the principal ones being: (1) Will manufacturing of new tools be done and if so, what kind and to what extent? (2) Will all classes of work pertaining to the upkeep of tools for every department be performed? (3) Equipment should be practical both as to size and design with a view to future requirements or expansion.

For the above groups, the following machines are suggested. The description of individual items is brief and confined to the kind or type of machine and principal dimensions or features. The maker's name has been purposely omitted. All machines should be individual motor-driven and equipped with suitable push button control. For convenient reference, the machines are classified and listed by consecutive item numbers.

Group No. 2.—Equipment for medium size shop doing mostly maintenance work

Item No.	Nominal size	Type and kind of machine	Special equipment or extra attachments
1	20-in. by 10-ft	Engine lathe	Taper attachment; 16-in. four jaw independent chuck.
2	14-in. by 6-ft	Toolroom lathe	Taper attachment; draw-in attachment, universal relieving attachment, and one universal and independent chuck.
3	No. 3	Horizontal, knee type universal milling machine.	
4	16-in.	Crank shaper	Universal table.
5	20-in. by 1¼-in. capacity	Upright drill press	Reversible; compound table; universal vise.
6	10-in. by 36-in. by 24-in. table travel	Medium service universal cutter and reamer grinder	Complete with power and hand feeds with all attachments.
7	¼-in. to 3-in. capacity	Twist drill grinder	
8	Capacity up to 3-in.	Tap grinder	
9	Capacity for all sizes.	Universal die chaser grinder	
10	14-in. by 2-in. wheels.	Double floor stand grinder	
11	Medium size	Floor stand type arbor press	
		Heat treating equipment	
12	8-in. by 12-in. by 26-in.	Furnace	Electric or gas.
13	4-in. by 8-in. by 12-in.	Furnace	Electric or gas.
14	24-in. by 36-in	Oil immersion tank	36-in. by 36-in. water jacket.

Miscellaneous

Air flow meters.
Air tool testers.
Scleroscope and other measuring or testing instruments.

Regarding the first group of equipment in the above list (comprising 33 items), it should be remembered that while the number of machines may appear excessive, an outfit about equal to this would be required to handle properly the work of manufacturing on a paying basis, certain new tools, such as reamers, cutters, taps, forging dies, jigs, fixtures and other special tools in quantities for general use at all shops, in addition to maintaining all local tools. It is believed, however, that the necessity for manufacturing such tools as reamers, taps, drills, threading dies, etc., is diminishing and the possibilities for effecting savings in this line are very remote. This is due to keen competition among commercial manufac-

Group No. 3.—Equipment for smaller shop where the only work done is reconditioning of tools generally used on running repair work

Item No.	Nominal size	Type and kind of machine	Special equipment or extra attachments
1	20-in. by 10-ft	Engine lathe	Taper attachment; 16-in. four jaw independent chuck.
2	20-in. by 1¼-in. capacity	Upright drill press	Reversible; compound table; universal vise.
3	10-in. by 36-in. by 24-in. table travel	Medium service universal cutter and reamer grinder	Complete with power and hand feeds with all attachments.
4	¼-in. to 3-in. capacity	Twist drill grinder	

turers and the fact that several reputable concerns are now listing as standard such tools as were considered special a few years ago and were priced accordingly.

There are many special time-saving tools and devices which had their origin and development in the railroad shop being manufactured and used today, which cannot be obtained elsewhere. These, together with forging and forming dies or other equipment of similar construction, give reason for a full complement of machinery in the tool department of an up-to-date railroad shop.

In the second group (comprising 14 items) is shown such machines as may be considered adaptable for the average medium-size shop to take care of occasional replacements and specialties in the way of new tools and the complete repairs and reconditioning of existing equipment.

The third group (comprising only four items) is suggested for outlying shops to handle limited light repairs to local shop equipment and sharpen such hand tools as drills, reamers, taps, thread chasers and cutters which would otherwise have to be shipped to a larger shop for reconditioning.

Report on shop jigs and devices

If some shop jigs and devices are not direct labor savers, they perform certain operations more uniformly and correctly than would otherwise be possible and therefore help increase the efficiency of shop operation and reduce costs. The jigs and devices shown in the accompanying illustrations have been developed and are used successfully at various points on the Santa Fe, notably San Bernardino, Cal., and Topeka, Kan.

A device for repairing the worn tender conveyor screws of Duplex stokers is illustrated in Fig. 1. The mechanically guided oxy-acetylene cutting torch cuts off the worn part of the top of the screw at a uniform distance from the center line and a steel strip subsequently welded to the conveyor screw brings it back to the standard diameter. Referring to the illustration, it will be noted that the conveyor screw is capable of rotation between centers on an iron frame-work supported on two wooden blocks. A carriage with an adjustable clamping arrangement to hold the cutting torch moves parallel with the center line of the conveyor screw, being guided by four flanged wheels which roll on the bed plate of the device. A vertical projection on the carriage carrying a taper roll at the top governs the horizontal movement of the carriage by bearing on the spiral of the conveyor screw and keeps the torch tip at the proper distance for effective cutting. In other words, starting with the torch at the right end of the conveyor screw, revolution of the screw will push the carriage with the torch attached to the left, the tip of the torch always remaining at the same distance from the spiral which is being cut. The speed of revolution of the conveyor screw is adjusted to that required for efficient operation of the cutting torch.

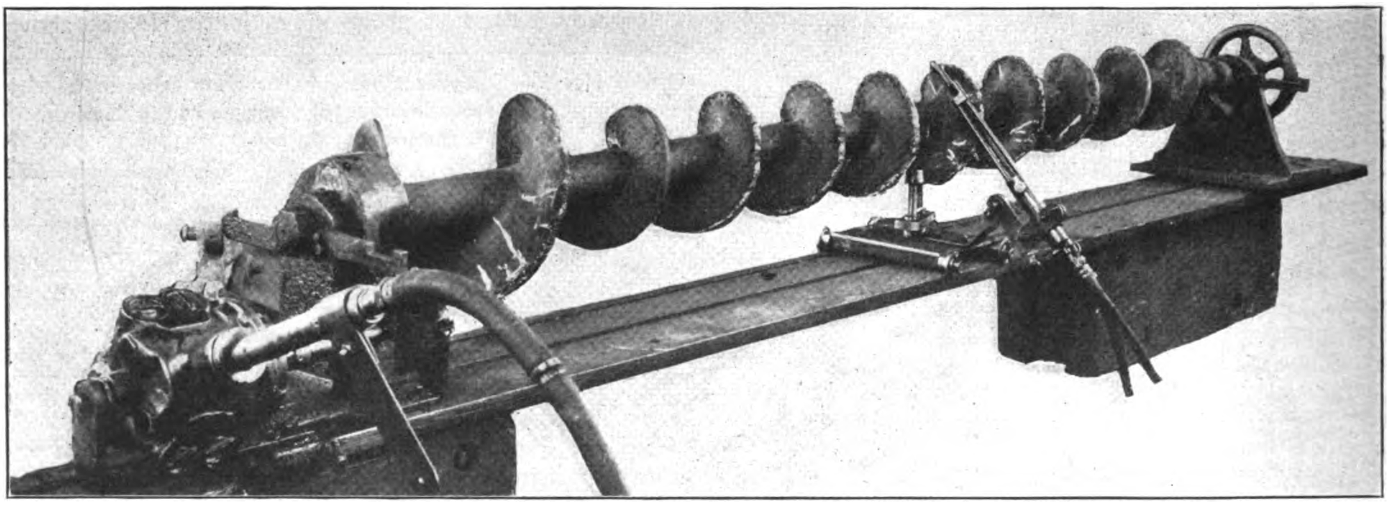

Fig. 1—Device for cutting off the worn part of Duplex stoker conveyor screws

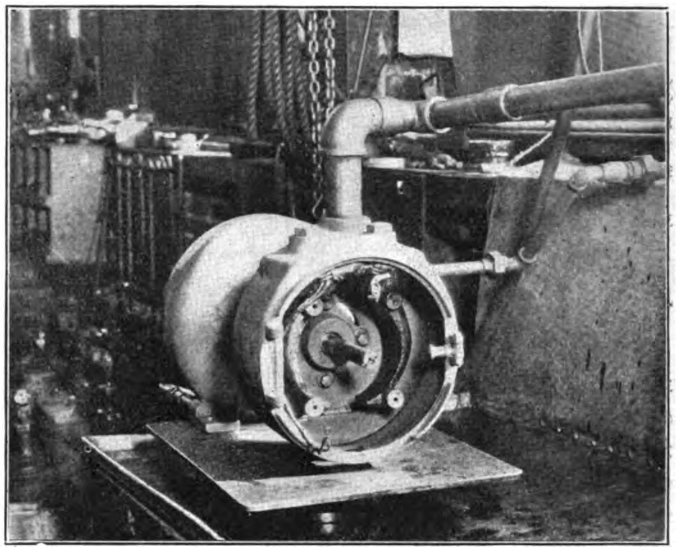

Fig. 2—Turning platform and work bench for repairing headlight turbines

A turning platform and work bench for use in repairing and testing headlight turbines is illustrated in Fig. 2. The platform turns on ball bearings and its use materially facilitates handling the turbines on the bench.

An ingenious and effective drill press clamp is illustrated in Fig. 3, clamps of this type being used on most of the drill presses in the Topeka shops for holding work. Bolts, U-clamps and blocks are largely eliminated, and set-up time is reduced proportionately. The construction of the clamp is plainly shown in the illustration, pressure on the work being obtained by pneumatic pressure in the cylinder, with a taper block on the end of the piston acting on the rigid right angle arm. Two substantial rolls on each side of the taper block reduce friction. A suitable

collar and retaining spring keeps the right angle arm up against the heavy 2½-in. nut, out of the way of any work on the drill press table while arranging the set-up.

Another device which assists in handling drill press work is the jig illustrated in Fig. 4. The length of time required for blocking up work at an angle on the drill press table is well known, and moreover, without the

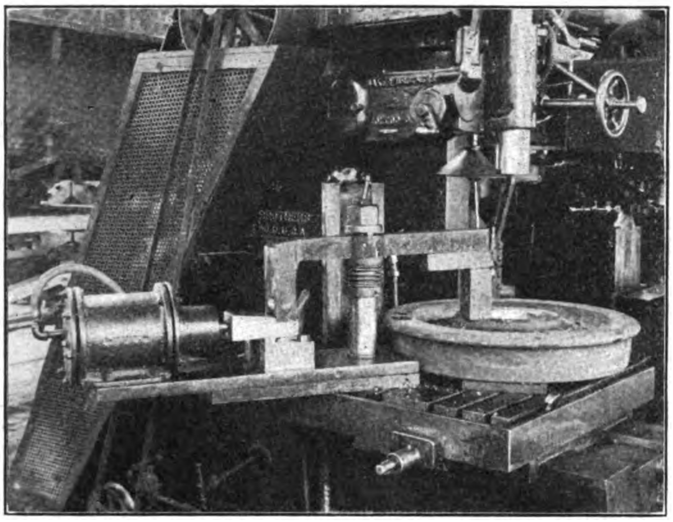

Fig. 3—Set-up time is saved with this pneumatic drill press clamp

exercise of considerable care and skill there is danger of ordinary blocks slipping and resulting in drill breakage. The jig illustrated consists simply of a bracket bolted to the drill press table with an auxiliary table capable of tilting at any angle. For drilling small holes such as oil holes in the spring hangers illustrated, simply tighten the two nuts on the bolts on which the auxiliary table pivots.

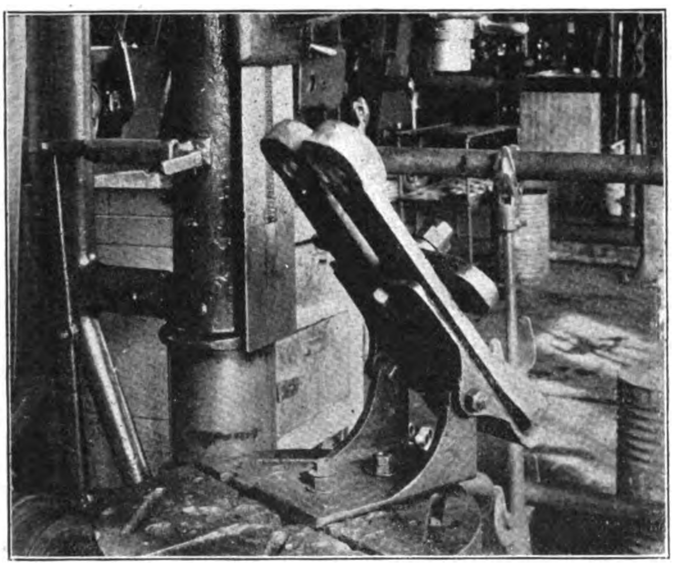

Fig. 4—Convenient drill press jig for drilling oil holes in spring hangers

This will develop sufficient friction to hold the table at any desired angle.

A convenient device for removing gears from a stoker shaft or other similar part is illustrated in Fig. 5. The framework of the device consists of a substantial U-shaped forging with the two ends turned over to form jaws and an accurately-cut 1½-in. screw threaded through a hole in the head of the puller. Any drive or force fit which is within the capacity of the device can be readily broken.

A particular advantage is its portability. It can frequently be used for removing gears in difficult places

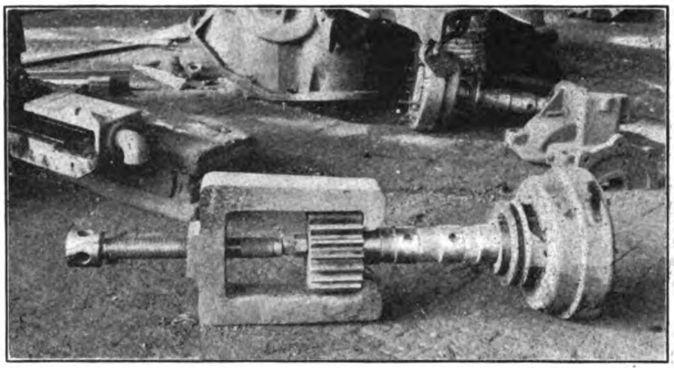

Fig. 5—Screw puller for removing gears from stoker shafts and other similar work

which would otherwise require dismantling the entire machine in order to take the particular shaft involved to the hydraulic press.

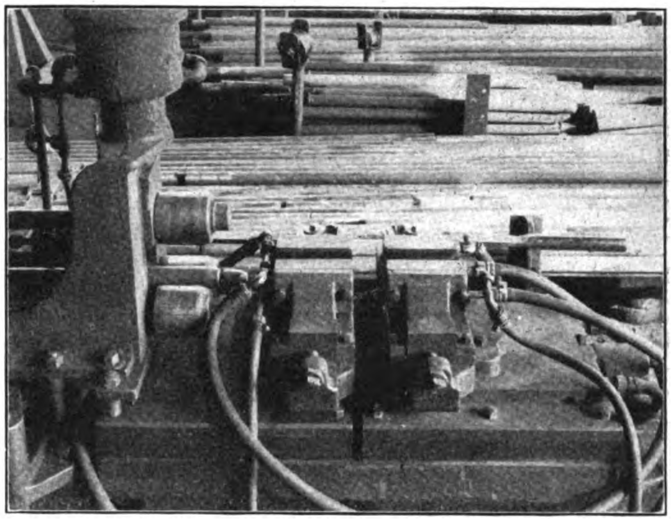

Fig. 6—Three-point roller as applied to modern electric flue welding machine

A three-point flue roller used with an electric welding machine is illustrated in Fig. 6. This device will roll the welds on flues smoother (on the inside as well as the out-

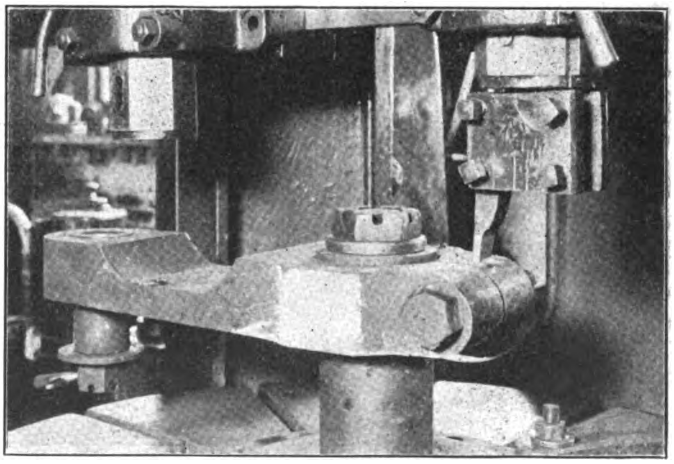

Fig. 7—Jig for holding eccentric crank arm while facing on boring mill

side) and do better work than with the old style roller.

A convenient jig for holding eccentric crank arms while being faced in a boring machine is illustrated in Fig. 7. By means of this jig the crank arm is easily and accurately set.

Some of the simplest shop devices are the ones which in the aggregate prove most effective and the chuck for turning and holding boiler check valves in a lathe, as illustrated in Fig. 8, may be taken as an example. This device permits the valves to be machined accurately and

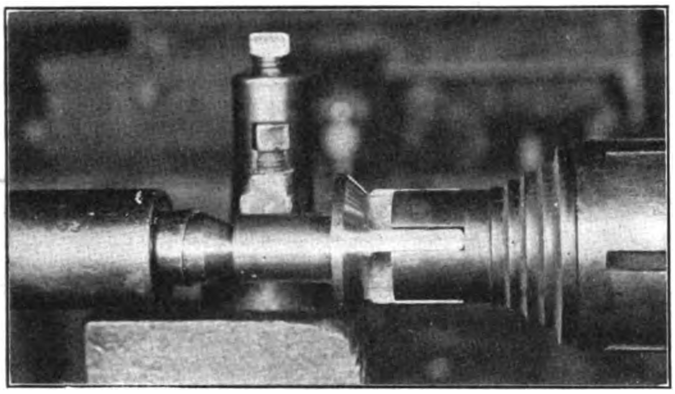

Fig. 8—Special lathe chuck for holding boiler check valves while being machined

in a minimum time. They are easily slipped in place and taken out again at completion.

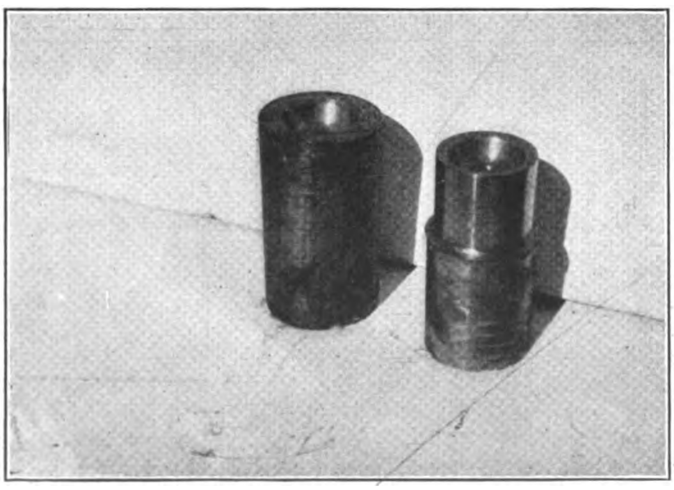
This report was signed by the chairman of the committee, Henry Otto, tool foreman, Atchison, Topeka & Santa Fe, Topeka, Kan., who requested that the association express its appreciation to J. R. Phelps, shop apprentice instructor of the Santa Fe at San Bernardino, Cal., for his able assistance in collecting data and photographs of many of the shop kinks.

Crank pins machined with counterbored ends

By J. Robert Phelps

Apprentice instructor, A. T. & S. F. shops, San Bernardino, Cal.

THE machining of locomotive crank pins in job lots is one of the common jobs in the locomotive repair shop. Considerable time can be saved in these



Finished and semi-finished crank pins with the ends drilled and counterbored

shops by adopting the following methods. The pins are first roughed out on a lathe and are then taken to a drill press where they are drilled and counterbored on both ends. The pins are now ready to be turned according to the sizes furnished by the wheel gang.

The lathe operator places the crank pins on the lathe centers in the holes which have been previously drilled in the pins. When the pin is finished, to size, its outside surface is true with the hole and the counterbore and is ready to be pressed in by the wheel press, thus eliminating any waiting at the last minute on the part of the wheel gang for the pins to be drilled. The machining of crank pins in this manner fits in well with the practice of keeping on hand a number of pins and axles all finished except for the wheel fits.

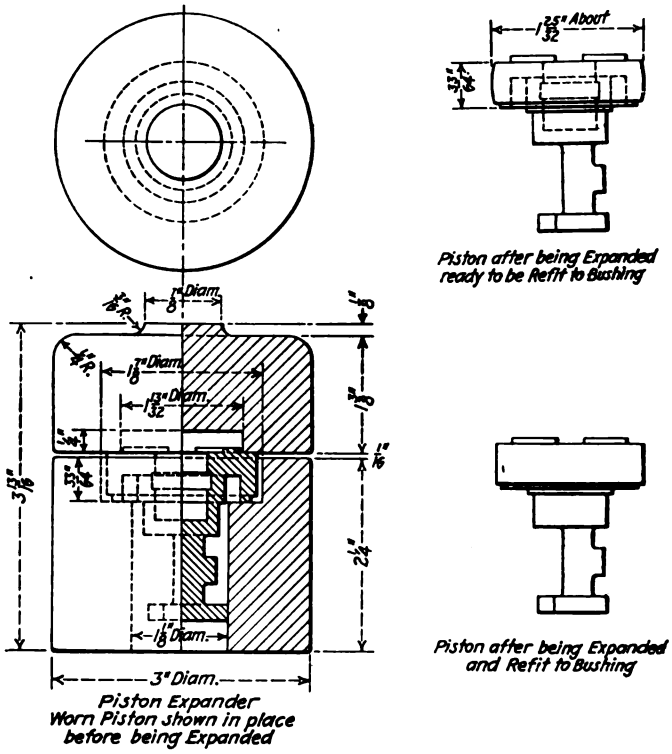
Piston expander for reclaiming feed valves

By N. T. Cline

Air brake foreman, P. & L. E., Pittsburgh, Pa.

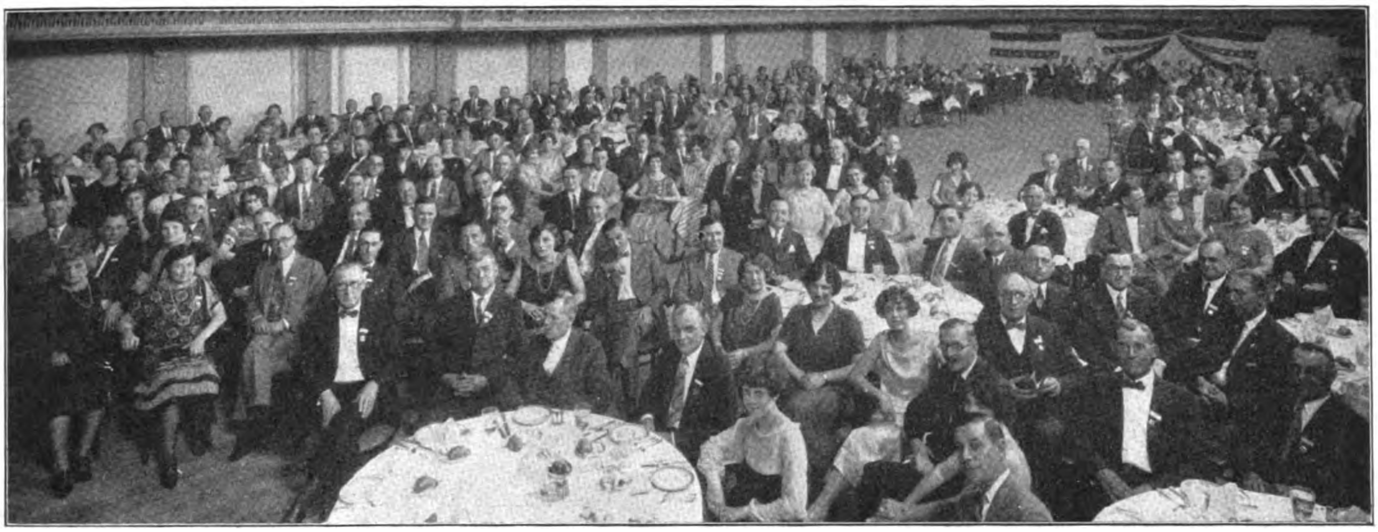
THE device shown in the drawing will be of benefit to air brake repairmen who are engaged in the repair and reclamation of air brake material. It has been used for reclaiming worn out *C*-6 and *B*-6 feed valve pistons at these shops for a number of years and has been found to be quite efficient for this work.

The operation of the device is simple and fast. Pistons



Device for reclaiming worn out C-6 and B-6 feed valve pistons

which have been worn down too small for further use are inserted in the device, as shown in the drawing, and the cap is placed on the top. The device is then placed under a hydraulic or air press that has sufficient capacity to force the two parts together. This causes the metal in the piston to expand sufficiently to permit machining to the proper size. The thickness of the piston is slightly smaller after this operation but the difference is so slight that it does not interfere with the operation of the valve. The two operations of expanding and machining take about six minutes.



Annual banquet of the International Railway General Foremen's Association, Hotel Sherman, Chicago, Ill.

General foremen meet at Chicago

Report is made on supervision of repairs to special locomotive appliances—Six other topics discussed

SIX reports were discussed at the nineteenth annual convention of the International Railway General Foremen's Association held at the Hotel Sherman, Chicago, September 8 to 11, inclusive, as follows: Automatic Train Control, Supervision of Repairs to Special Locomotive Appliances, Straightline or Spot System of Car Repairs, What Can the General Foreman Contribute to Obtain More Ton Miles per Shop Man Hour, Reclamation of Car and Locomotive Material, and Best Routing System to Increase Shop Output. A feature of the convention was the address on the third day by Roy V. Wright, editor of the *Railway Mechanical Engineer,* who made a strong appeal for a higher type of leadership in the railroad mechanical field, and pointed out the urgent need of definite plans for building men for the future. An abstract of Mr. Wright's remarks is presented below.

Election of officers

The officers of the association for 1926, most of whom were re-elected, are as follows: President, H. E. Warner, New York Central, Elkhart, Ind.; first vice-president, C. A. Barnes, Chicago & Western Indiana, Chicago; second vice-president, F. M. A'Hearn, Bessemer & Lake Erie, Greenville, Pa.; third vice-president, C. F. Bauman, Chicago & North Western, Winona, Minn. William Hall, Chicago & North Western, Winona, Minn., is permanent secretary-treasurer. William Mulcahy, Baltimore & Ohio, Garrett, Ind., and B. L. Davies, Baltimore & Ohio, Hammond, Ind., were replaced on the executive committee by J. N. Chapman, Illinois Central, Water Valley, Miss., and H. Keys, Baltimore & Ohio, Baltimore, Md.

Leadership—Building men for the future

By Roy V. Wright

Editor, Railway Mechanical Engineer

Many things have happened in the past 10 years which have brought about radical changes in railroad shop methods, practices and administration. The shop crafts strike, for example, in 1922 proved to be a terrible experience for both the men and the managements. It had one lasting and beneficial result. It forced both sides to face the situation squarely and to do some real thinking about their mutual relationships. The year 1922 will in all probability mark the passing of large strikes and lockouts in the railroad field. We are going back into the dark ages when we attempt to settle differences by brute force. There is no winner in such a contest—both sides lose, regardless of which one may come out ahead.

"If a house be divided against itself, that house cannot stand." We are coming into a period of co-operation. The ownership of a corporation or railroad is vested in so large a number of people that the executives act in the capacity of trustees and are just as much employees as are the workers in the ranks. In a very real sense, therefore, the executives and representatives of the managements and the workers are *co-workers.*

We now have several different types of co-operative endeavor in the railroad shops, extending all the way from organized co-operation on the part of the labor unions to various forms of so-called employee representation. All of these methods tend to emphasize the importance of the human element in the organization and to restore to some small degree, at least, that intimate contact between the management and the worker which was lost with the coming in of the present industrial age. Then, too, the limelight has been focused on the keystone of the arch in the organization—those men, foremen and subordinate supervisory officers, who come in intimate contact with the workers and lead them.

The foreman and his training

These foremen have the responsibility of interpreting the policies of the management to the men and in turn interpreting the needs of the men to the management. They hold a most vital and strategic position. It would seem that they should be selected only with the very greatest care and that they should receive a most careful course of training in leadership.

A bright young man oft-times in these days with a high

school training, will go into a shop and spend four years as an apprentice in training to become a mechanic. He has much to learn and at the end of his apprenticeship is still in many respects just a beginner. He does possess a certain degree of manual skill and understands how to operate certain machines and equipment. If he continues to develop, becomes a master craftsman and has a good personality, he may become a gang leader or foreman—indeed, if he is willing to study and work hard and possesses any great degree of executive ability, he may climb far up the ladder of success.

There is no more delicate or complicated piece of mechanism than the human being and no two individuals are alike. Treated and directed rightly, a worker will function with enthusiasm and great efficiency—misunderstood, even to a slight degree, and his efficiency and interest may fall off greatly. Surely, if it takes four years to make a mechanic who must deal with inanimate objects and operate relatively simple machines, it should take years of careful and painstaking work to prepare a man for a position in which he must lead and direct his fellow workers.

How much special training of this sort must a man have to qualify for the position of foreman? You know even better than I do how much he gets. It is, of course, true that certain men are born with the faculty of understanding their fellows and are natural leaders. They are comparatively few in number, however, and even these fortunate ones can benefit greatly by understanding clearly the basic principles upon which successful leadership rests. Not so many years ago people would have smiled if management had been referred to as an art or a profession. Today it is recognized more and more generally as a science.

Have we not a real task before us in training men who must occupy positions of leadership in the future and of helping those who now hold supervisory positions to take advantage of the great amount of information which has been developed in recent years on the art of human leadership?

This information is available for several sources and in different ways, if we will but busy ourselves to take advantage of it. On one road, at least, successful foremen training classes have been conducted under local leadership, but with the aid of a course provided by the extension department of a state university. Other universities have similar courses and I know of at least two different railroad points which are going to put on foremanship training courses this fall with the aid of the state universities.

Then there are a number of roads on which foremen's clubs have functioned. The programs of the staff meetings on many roads have been broadened to include discussions of problems relating to successful leadership. Several correspondence school study courses on foremanship training are available. Some roads believe in sending their foremen and officers to visit shops on other roads in order that they may broaden their ideas and see how other shops are administered. A few mechanical department officers are asking their associates to present written criticisms of articles in the technical papers or reports before railroad clubs or other organization. At least one of these officers is concentrating this sort of a campaign on articles relating to foremanship training. There are other ways in which the foremen are being assisted in getting a better idea of the principles underlying successful leadership, as well as on up-to-date methods and practices. I imagine a most productive session of this convention could be entirely devoted to the exchange of practical experience on this question.

Getting back to the very root of the matter, several mechanical department officers have suggested that the best type of foreman can only be produced by selecting the apprentices with the greatest possible care and then giving them a thorough apprentice training along the lines which have been so well worked out on the Santa Fe. I shall not attempt now, however, to discuss this matter of apprenticeship. For at least a quarter of a century the *Railway Mechanical Engineer* and its predecessors have consistently and aggressively advocated more modern apprenticeship training methods. Some progress has been made in this quarter of a century, but it is only within the past two or three years that the roads at large have shown any very great interest in this question and too many of them are still sound asleep or dozing.

Helping the young men

A splendid movement has been started in the interests of the boys and young men in railroad service. On some roads unusual care is taken in selecting boys for positions in the various departments. On other roads little if any attention is given to this vital question. Even under the best conditions boys are often found in a department or on a class of work who by nature are much better fitted for some other type of work. Some boys cannot be happy or do their best work unless it is particularly adapted to their peculiar abilities. Something must be done to help these boys find the positions in which they can function to the best advantage. More than this, however, any boy can do much better work if he receives the right kind of coaching and encouragement. I am speaking now not of apprentice training, but of the more or less informal contacts with the boys. It is doubtful if any other single investment will mean so much to the railroads in the future as that which can be made by the foremen and supervisory officers, as well as by some of the men in the ranks, in showing a real interest in the boys' welfare and giving them a reasonable amount of encouragement.

The Transportation Department of the Y. M. C. A. held a boys' or younger men's conference in connection with its triennial conference at St. Louis two years ago. An attempt was made at this week-end meeting, which extended over three days, to give the boys some idea of the opportunities for life work on the railroads and to help them find themselves. Briefly, each boy filled out a form answering questions as to the kinds of work which appealed to him, what position he would like to hold ten years from now, etc. On the basis of these answers the boys were divided into small groups, each of which was assigned to the practical railway officer who could best talk matters over with the group and advise the individuals in it. I shall not take more time to explain just how the program was carried on, but it proved so successful that it was found necessary to hold a similar national meeting a year later at Detroit, and a third meeting of this kind is scheduled at Pittsburgh this fall. In addition, one system, the Chesapeake & Ohio, carried out a similar program for its own boys and special care is being given in following this up and getting the foremen and officers to take a larger interest in all of the boys on the system.

After all, the thing that counts in a movement of this sort is the actual concrete results. I know of no way in which these can be better expressed than through the boys themselves. Five months after the Younger Railroad Men's Conference at Detroit, I wrote to all of the boys, asking them if they had received any help or inspiration from the Detroit conference, and whether they had been able to pass this on to boys back home who were unable to attend the meeting. I want to read just a few typical extracts from the letters that I received in reply.

Before doing so, however, just a word about the Detroit conference.

Results of Detroit conference

The Detroit Younger Railroad Men's Conference was attended by 277 boys and young men and 51 leaders. Naturally, a certain percentage of the more ambitious and progressive boys went back home and started something. On the other hand, probably a large percentage of the boys personally profited greatly from the experiences at Detroit, but have not accomplished a great deal for their comrades back home, except that a change in attitude or conduct may have impressed itself upon those with whom they come most intimately in contact. Because the boys were carefully picked, undoubtedly the percentage of self-starters is fairly high.

Undoubtedly, also, the best results in specific communities have been obtained where the community was represented by several delegates. Where only one or two boys have come from a given point, it has been difficult for them to carry back and impress the spirit on their comrades, unless they are of unusual ability. Typical comments follow:

Car repairer apprentice, Boston & Albany.—"I would like to state that from the educational point of view, or in shops with some high employee of the railway company."

Machinist apprentice, Chicago, Rock Island & Pacific.—"Another value is to hear big railroad men talk—not only talk, but get acquainted with them. It's something that every boy and everybody doesn't get a chance to do. You also get acquainted with many railroads, railroads that you never hear about. First thing you'll ask, 'Where is this railroad and how big is it? And what are the apprentices doing?' You learn a lot of those things just from the boys sitting next to you at the dinner table, from the boys who are many miles from home attending the conference."

Machinist helper apprentice, Delaware, Lackawanna & Western.—"That conference has shown me what really great and many opportunities there are in the railroad game. It has encouraged me to study my daily work in the shops with greater interest. It has shown me that my employers are greatly interested in what the young men on our road are doing and that our employers are anxious to help us in our struggle to get ahead. Since the Detroit conference there have been greater activities among us apprentices at the Scranton shops of the Lackawanna."

Machinist apprentice, Lehigh Valley.—"First, it has shown me that the more we come in contact with the big business man, the more we take to him and understand

H. E. Warner (N. Y. C.)
President

C. A. Barnes (Belt Ry. Chi.)
1st Vice-president

F. M. A'Hearn (B. & L. E.)
2nd vice-president

Wm. Hall (C. & N. W.)
Secretary

fact from each and any point of view you may look at it, I personally have failed to find the words that will express the great value and helpfulness that I got out of it. It has shown me a different spirit towards my work and also towards my fellow workmen, also a cleaner and better way to live."

Machinist apprentice, Boston & Albany.—"Until the conference, things were sort of dead, but after the conference the fellows knowing the real meaning of service got to work. A greater interest was taken in our Christmas savings clubs. Americanization classes were started and a circulating library commenced. The officials hearing our reports soon understood that we were out to win and all sorts of help followed."

Clerk, Chesapeake & Ohio.—"Since the return of the other boys, we have gotten together and with the help of Mr. Watkins, our Y. M. C. A. secretary, we have organized a club known as 'The Ambitious Club.' The object of this club is to get the younger men and the employers in closer relationship. This club meets at the Y. M. C. A. every Monday night for about one hour and 15 minutes. The meetings are open and the business of the club is discussed. The rest of the time is spent listening to short talks and discussing questions arising in the office and him. Second, it seems as if the work comes easier to us if we have a better feeling toward our employer. One thing I have learned since I came back from Detroit, and which I think the conference was to blame for, and that is not to form an opinion of a person until you have heard some of his good deeds as well as his wrong ones. Because if you stop to think, none of us is perfect. It also proved that to co-operate is to secure benefits for both parties and creates a better feeling between both employee and employer. And that is to get everything out of it you can, especially to find out if you are in the right job. I think this was one of the most important questions asked. Because if you are not in the right job you are discontented and nothing seems to go right."

Sheet metal worker, New York Central.—"Possibly the most individual help was obtained through the Get-Together Meeting. Every young man was given the opportunity to discuss his problems with some older man who was well versed in that particular line of work. Such difficulties as: what a young man could make of himself with his own abilities, how a young man working at a trade which was not adapted to his standard of knowledge or abilities could become a better workman at some other branch of the service and at the same time serve his em-

ployer to a better advantage, were thoroughly reviewed and proved to be possible."

Clerk, Reading Company.—"When we returned home from the conference at Detroit, we decided that we should help the other fellows of our road. As a result of this decision we five who represented the Reading Company at the Detroit conference, organized a younger men's club on our road.

"The club is known as the Reading Company Younger Men's Club. It meets the first and third Friday of each month, in the Y. M. C. A. auditorium.

"The purposes of the organization are as follows: (a) To develop its members spiritually, mentally, physically and socially. (b) To foster and promote a spirit of unselfish service. (c) To assist young men in finding their proper vocation. (d) To promote good fellowship among the younger men of the Reading Company. (e) To promote a spirit of friendly co-operation between employer and employee."

Apprentice instructor.—"Personally, the Detroit conference was the biggest thing in my life and I see the railroad, my work and my boys and superior officers in an entirely different light than formerly. Railroading is no longer just a job, but the most important factor in the progress and development of our country. I do not know of a field that presents such a challenge or opportunity for service, improvement in methods, equipment, development and better human relationships."

Conclusion

I shall let these expressions speak for themselves.

Let us remember that the railroads are vital to the welfare and prosperity of the states and nation. If our foremen and supervisory officers are keen to take advantage of those things that will help them to improve their leadership ability and if we can select, train and inspire the new recruits so that they can find that work for which they are best adapted and in which they can be most happy, then we shall have gone a long way to safeguard the railroads of the future and the best interests of the communities which they serve.

Report on repairs to special appliances

When a booster engine is received at the shop, the engine is placed on a pit and the booster removed for overhauling. The booster binder is taken down and placed low enough to permit the axle gear to pass over, and the wheels to be run clear from the locomotive. After all wheels are removed, the locomotive frame is dropped down far enough to permit the removal of the booster engine by means of a specially constructed four wheel truck provided especially for this purpose. After the booster is removed, it is taken to the booster repair department, where it is placed on horses, at a convenient height for easy access to all parts, the booster resting on the engine bed and axle bearing, keeping the cylinder cock rigging free for testing.

The covers are then removed for washing, and the oil drained off. After it has been washed, each part is removed and inspected. The first part removed is the idler gear, rocker and pin. In most cases the gear bushing has been worn to such an extent as to cause lost motion in the gearing of the booster with the locomotive, and has to be replaced with a new bushing. If the gear is worn more than 10 per cent it is also replaced. It is seldom that a broken rocker is found.

The next part is the clutch cylinder. This is removed from the booster and given a thorough overhauling. Most of the trouble is found with the piston and rings; either, the piston sticks in the cylinder or the rings in the piston. These parts are washed thoroughly with kerosene, and made to move freely. When a clutch cylinder is removed a new gasket should be applied, as when the cylinder is assembled, to be in first-class condition, it must be air tight.

The air lines are then tested in the booster, after which an inspection is made of the pistons and valves. The back heads are taken off and the piston rings examined. In a great many cases it is found necessary to apply new rings.

The valves are then checked up to ascertain if any part of the valve gear is out of line. Sometimes, the valve rocker is found to be bent; in such cases, repairs are made. If everything is found satisfactory the heads are replaced and steam manifold inspected for cracks or steam leaks.

The cylinder jacket is looked over and repaired if necessary. To finish up the back end of the booster, the cylinder cock rigging is checked. In a great many cases the fingers are broken or too short, or the rigging out of line with the cocks, which makes it necessary to take the whole rigging apart for repairs.

When this work has been completed, the swab cups, the piston rods, the valve stems are repacked. An inspection is then made of the crossheads and guides. The crossheads are rebabbitted and machined, and guides are lined up to suit.

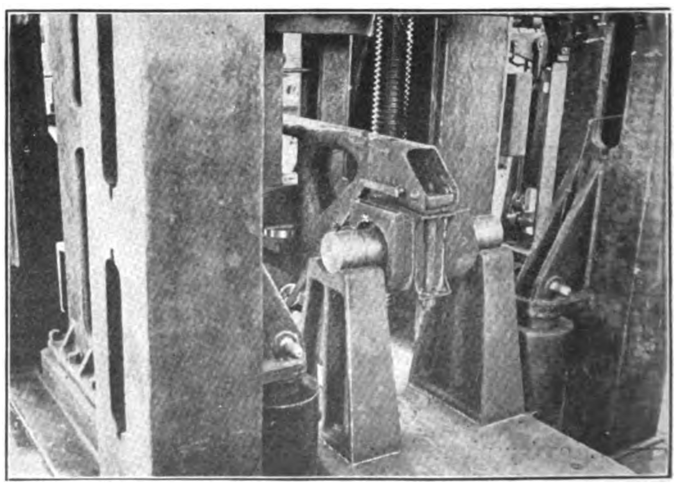
The next operation is the connecting rod bushings. This is a simple matter as these bushings are standard and are easily replaced.

The valve rocker bushing gives very little trouble. If found necessary to renew, it is babbitted and run in. The eccentric crank is next. If any lost motion is found there it must be replaced or a new crank pin is applied. In some cases both parts have to be replaced. The crank shaft and bearings are looked over and if the gear is found satisfactory, bearing caps are adjusted by means of liners being removed. If the gear is worn more than 10 per cent, it is replaced by a new crank shaft, likewise with all other gears in the booster.

When the covers and cylinder jacket are repaired and put back, the booster must be oil tight. The booster binder is replaced and axle bearings inspected. If no repairs are necessary, the booster is ready to be reapplied to locomotive.

The maintenance cost of boosters is low.

The report was signed by the chairman of the committee, R. D. Kocher, Delaware, Lackawanna & Western, Scranton, Pa.



Testing truck side frames at Lehigh University

Blacksmiths' Association Convention

FOLLOWING are abstracts of a number of papers and reports which were presented at the twenty-ninth annual convention of the International Railroad Master Blacksmiths' Association, held at Cleveland, Ohio, August 18-20, 1925. A report of this convention in which abstracts of a number of papers were also given appeared in the September, 1925, issue of the *Railway Mechanical Engineer*, page 575.

Drawbars and pins

By John P. Reid

Master blacksmith, Missouri Pacific, Kansas City, Mo.

All drawbars and safety bars are manufactured from hammered iron furnished from specifications drawn up in the office of the engineer of tests. The practice of closing the pin holes and shortening the draw bars has been discontinued on the Missouri Pacific. When a bar becomes worn in the pin holes, it is scrapped and manufactured into spring hangers or other parts.

We punch the pin holes on all drawbars used on our switching power and preheat when the bars are completed so as to remove all hammer strains that may have been set up during manufacturing. Too much care cannot be given the forging of draw bars. A "pull over" or "cold sheet" may be the cause of a heavy loss to the company. We drill the pin holes on all drawbars and safety bars on our heavy power, both freight and passenger, and preheat when completed which, I believe, goes a long way toward eliminating drawbar failures.

Since we have discontinued shortening, slabbing and closing the pin holes and replacing with new bars, a drawbar failure is a very rare thing. We are eliminating the offset drawbar. We all know that offset drawbars do not give the forging a fair trial. The offset is liable to cause a separation in the structure that cannot be seen with the eye and a surface crack will appear in due course of time. The inspector may or may not see it and the ultimate result is a drawbar failure.

The new power being purchased by the railroads is heavier and the best hammered iron is none too good for drawbars. We also use double refined iron for drawbar pins which comes in dimension lengths. The pins are headed and pointed and punched for a split key on a forging machine. We are not allowed to upset any pins to take care of worn parts. We replace with new pins and use old pins for other repair purposes such as boiler lugs, braces, etc. We do not allow any quenching of drawbars or pins at any time. This is a dangerous practice.

Reclamation

By Frank Laukat

Blacksmith foreman, Oregon, Washington Railroad & Navigation Company, Portland, Ore.

We know that tire steel makes good shear blades, reamer extensions and forging machine dies, and through the co-operation of the tool room foreman it can be used extensively with good results, with the exception of handle punches and side sets. When one considers the cost of making the latter and the danger in using them when made of tire steel, I feel that it will not take any one long to disapprove of such a practice.

We make piston nuts from scrap steel hollow locomotive axles by drawing them down to a hex bar about 8 in. long, letting the hole close as it will and then annealing. The bar is then taken to the machine shop where it is sawed up to proper lengths and the nut is ready for drilling and threading. We also make dry pipe sleeves and flue sheet rings from hollow axles by cutting them up at the cold saw to proper lengths and then drifting them out on the hammer. The steel in these axles is good and we have no trouble in drifting them.

All piston rods are made from scrap steel car axles. Taylor iron locomotive axles are usually saved for drawbars, and I do not know of any material on hand at the railroad shops today that is more suitable for that purpose.

Heat treatment of steel and iron

By Frank Sillix

Master blacksmith, St. Louis-San Francisco, Springfield, Mo.

The first step in annealing always consists in heating the metal past its critical temperature, because by so doing the existing structure, however coarse, is destroyed. Should the temperature of the steel remain below its critical range, no structural change would take place and the annealing would not be effective, except in cases where it is simply desired to remove strains produced by cold working. Strains can be removed in this case by heating to slightly below the critical range. This, however, has no effect on the grain size. On the contrary, should the temperature of the metal be carried considerably above its critical range, the structure of the metal, which was finest within the critical range, begins to coarsen on further heating and continues to grow as the metal cools slowly back to the critical range, so that a coarse structure is the final result. In order to anneal steel properly, it must be heated through its critical range and kept at a temperature as close to the upper part of that range as possible. The annealing temperature will vary with the carbon content, so the greater the carbon content of a steel, the lower will be its critical temperature.

The temperature at which these structural changes occur in steel is not absolutely fixed for any given carbon content, on account of the fact that this temperature depends somewhat on the rate of heating. It follows that there is a range of temperature in which these effects take place, rather than one single temperature. The words "critical range" are used to express the temperature range within which the structural changes outlined above take place.

The following ranges of temperature are recommended by the American Society for Testing Materials:

Range of carbon content, per cent	Range of annealing temperature, deg. F.
Less than 0.12	1610 to 1700
0.12 to 0.29	1540 to 1600
0.30 to 0.49	1500 to 1545
0.50 to 1.00	1455 to 1500

The locomotive forgings which we receive for rods, crank pins, driving axles, etc., and the billets received for the same purpose, have a carbon content of from 0.52 to 1.38 per cent, usually nearer the upper figure. An annealing temperature of 1,490 deg. F. to 1,530 deg. F. would, therefore, be correct for this class of work. Steel castings require a somewhat higher annealing temperature than forgings as the structure of a casting is more difficult to break up. The steel castings which we receive contain about .30 per cent carbon and should be annealed at about 1,650 deg. F.

The steel should be kept long enough at the annealing

temperature to be heated entirely through to that temperature. An exposure of 45 min. for each inch of thickness of the heaviest portion of the forging is recommended. For steel castings, an exposure of 60 min. per inch of thickness is desirable to secure thorough refining of the grain.

The hardness and strength of the steel depends upon the rate of cooling from the annealing temperature. Rapid cooling, as by quenching in oil or water, gives a hard metal which is somewhat brittle. Slow cooling, as in the furnace, gives the maximum softness and ductility at the sacrifice of a certain amount of strength and elasticity. Cooling in air gives properties between the two extremes.

The lower the carbon content, the more quickly may the steel be cooled without affecting too deeply the ductility and hardness of the metal. For instance, steel containing not over .15 per cent carbon may be quenched in water and still remain soft and ductile, while a medium carbon steel forging, say from 38 per cent to 52 per cent carbon must be cooled in air or in the furnace, for if quenched it would be too hard and brittle.

Since large objects cool more slowly than smaller ones under the same conditions, it is evident that the conditions of cooling should also be regulated in accordance with the size of the object. If a large and a small piece of steel of the same carbon content were heated to annealing temperature and then removed from the furnace and cooled in air, the smaller piece will be the harder of the two, since it will have cooled more rapidly. Locomotive forgings of fairly large size, such as rods, piston rods, and large crank pins, should be cooled in air rather than in the furnace, as this will produce a somewhat stronger steel, while, on account of their size, they will not cool rapidly enough to make the steel hard.

If the steel is heated above its critical range while in the annealing furnace, the grains grow in size and the steel is thereby weakened. If the steel is heated to several hundred degrees higher than its critical range, the grains grow to a very large size, producing a very weak and brittle metal, which may break when subjected to a slight shock. Since the growth of the grains takes an appreciable time, it follows that the longer the steel is held at a temperature above the critical range, the larger will the grains become.

Steel which has been overheated in the annealing furnace has a structure very much like that of a steel casting as removed from the mould, being weak and brittle. The overheated steel can be restored by allowing the steel to cool to room temperature, and then reheating to the proper annealing temperature, holding it at this temperature for sufficient time to permit the coarse structure to be completely destroyed, and then cooling as usual. If the steel has not been burnt, this treatment will completely restore it.

From what has been said above regarding the influence of temperature on the properties of steel, it will be evident that accurate means of measuring the temperature of the work in the furnace are absolutely necessary for proper annealing. This measurement of temperature can only be done by suitable pyrometers, which should be frequently checked for accuracy of reading. Most pyrometer installations in annealing furnaces indicate the temperature of the furnace and not the temperature of the work. These two temperatures are not necessarily the same, since the work lags behind the furnace both on heating and cooling.

It goes without saying that the heating of the steel must be as nearly uniform as possible, as otherwise there will be differences in the structure of the same piece and the possibility of strains being set up. The same applies to the cooling from annealing temperature.

Steel forgings of medium carbon should be annealed in all cases after forging, bending either hot or cold, or after any form of cold working. They should also be annealed at intervals during use, especially if they are subjected to heavy working stresses, as annealing removes the effects of fatigue. Annealing should also be given to all medium carbon steel parts which have been built up or otherwise repaired by any form of welding, as well as those cut by means of the oxyacetylene torch. The intense localized heat of welding or gas cutting produces a strained condition in the metal adjoining the weld or cut which is very likely to result in cracks if not removed by annealing.

In annealing, iron should be heated to about 1,250 deg. F. just so it will relieve the stress on the iron if there is any present.

Discussion

The importance of proper heat treatment of iron and steel in the railroad blacksmith shop was emphasized by many of those present. The old haphazard method of hardening by quenching was generally condemned and it was agreed that the analysis of the steel should regulate the heat treatment. A much better job can be obtained if a part is annealed or normalized after it has been forged or hammered. Normalizing seems to get better results than quenching.

One of the speakers brought out the fact that placing cold billets in a hot furnace causes the outside portion to break away from the center. This is caused by the billet heating too rapidly so that the outside portion becomes hot while the inside is still cold. The rapid heating changes the content of the outside surface and in order to prevent this occuring, billets should be preheated before being placed in the furnace. Some blacksmith shops make it a practice to heat billets over night. In such instances, the billets are placed in a cold furnace and it is then brought up to the critical temperature. All furnaces should be equipped with pyrometers.

Pieces eight inches in diameter should be heated ten hours, plus four hours. The four hours is required for heating and the ten hours for normalizing.

Frame making and repairing

By William Banks
Master blacksmith, Yazoo & Mississippi Valley, Vicksburg, Miss.

Frame making is practically a thing of the past at our shops, as all new frames applied at the present time on locomotives are of cast steel. We have not made frames in the blacksmith shop for several years and, I believe, about all of the other railroads are doing likewise. But, for the benefit of those that are still making frames in the smith shop, I will endeavor to explain the method we used in making locomotive frames.

We slab scrap iron axles which are heated in an oil furnace. After these axles are slabbed in billets from sizes six inches to eight inches square, the billets are heated in a furnace and the pedestal jaws, both top and lower, are blocked into sizes suitable for the frame. After this operation, the front and back pedestals are welded to the top and lower rails. These welds are made in the forge, after which these sections are welded together between the pedestal jaws which completes the frame. It is essential to keep the frame straight at each weld made and also to expand the lower rail after the last weld is made so as to avoid undue strains which originate from contraction. When new sections are required they are welded on in the smith shop. Also all frames that have been welded by the autogenous process are then taken

down, the welds removed and new sections are welded in at the smith shop. This only applies to locomotives that are in for general or classified repairs.

In regard to repairing frames, we use both the acetylene and electric process and have experienced very good results. But we all know it depends on the operator as to the kind of a job we get. If a frame is not welded properly in the smith shop, it will not hold up.

Tools and formers

By S. J. Uren

Blacksmith foreman, Southern Pacific, Sacramento, Cal.

Tools and formers are a necessity and no blacksmith shop can get along very well without them. If you have a steam hammer, hydraulic forge press, forging machine, bulldozer, air bending machine, or even an anvil in your shop, what good are they to you unless you have tools and formers. In this connection I will describe some of the tools and formers used in the forge shop of the Southern Pacific, Sacramento, Cal.

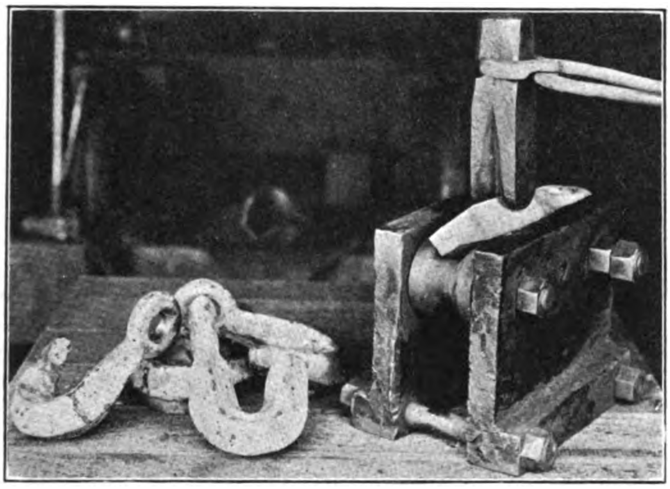


Fig. 1.—Formers for shaping wrecking chain hooks on a steam hammer

In making wrecking chain hooks, a piece of mild steel two inches square, is cut 11 in. long. The eye is formed in an eye forming tool placed on the steam hammer and the other end is slightly tapered. It is then heated the entire length and placed in the grooved rollers of the tool shown in Fig. 1. The top tool is then placed in the center as shown and a few blows of the steam hammer bend and press the piece down between the two grooved rollers and the hook is completed.

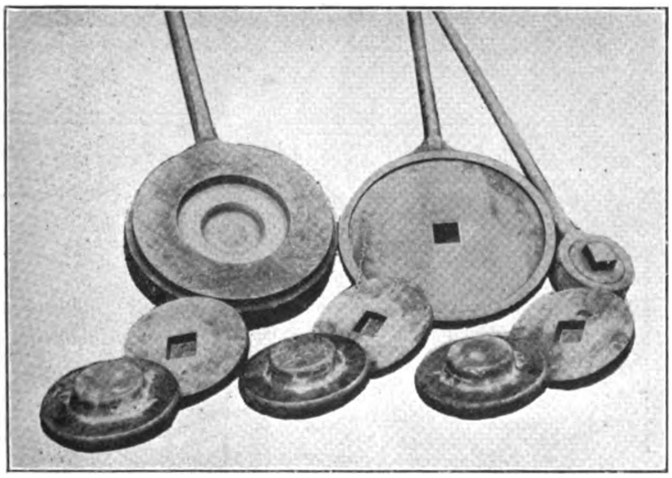

Fig. 2.—Dies for forming side rod collars

Side rod collars are made in a simple tool placed on the die of a forging press. A piece of four-inch mild steel is heated and placed in the tool. The ram on the forging press is then lowered on the material which easily presses it into shape in the tool shown in Fig. 2. The cap or gage is placed on top of the tool for the marking of the square hole in the center of the collar. The cap is then removed and a 1¾-in. square hole ⅞ in. deep is pressed in the collar which is then completed. This tool can also be used on the steam hammer to good advantage if you have no forging press in your shop, but the collars are pressed into shape much easier with a press than from blows of a steam hammer.

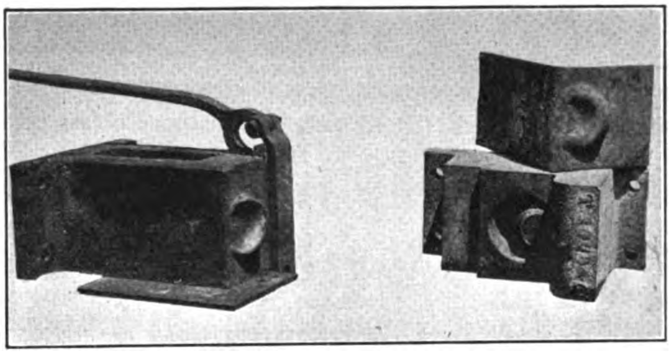

Fig. 3.—Bulldozer dies for manufacturing push pole corner irons

The bulldozer is a handy machine to have in a shop where there is a large quantity of bending and forming to be done, such as arch bars, drawbar yokes and pressing of sheet steel into various shapes that are now being used on modern freight cars. Push pole pockets for freight cars are easily made on a bulldozer with the dies shown in Fig. 3. The female former is bolted to the movable face of the machine and the male former is bolted to the stationary face. The material is then placed on a rest on the male former and held in place with a hinged clamp bolted to this former. The female former moves forward making the impression in the pocket and bending the material at right angles at the same time the impression is made.

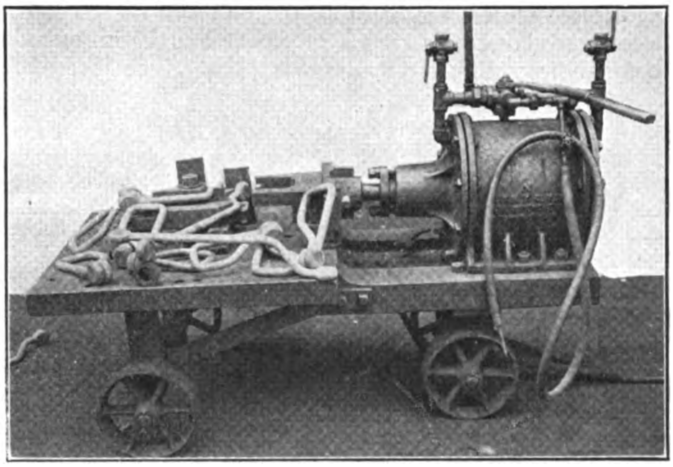

Fig. 4.—Former for offsetting and shaping brake hangers

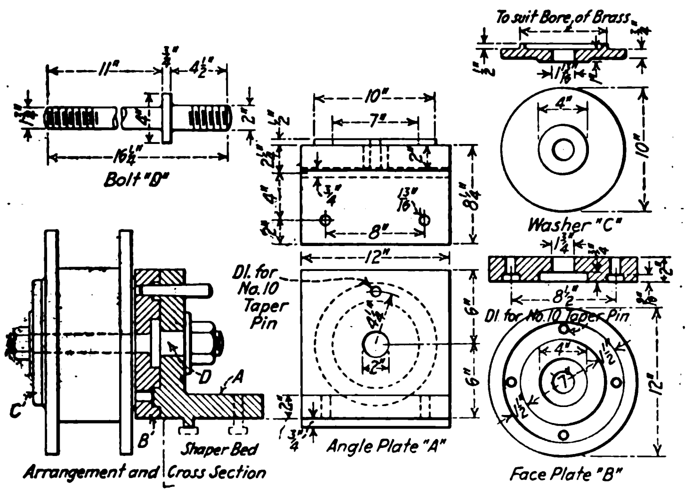
Brake hangers are easily bent to shape in formers attached to the small bending machine shown in Fig. 4. The ends of the brake hangers are first upset on a forg-

ing machine. They are then heated the entire length, placed in the lower part of the former on the bending machine, which is cut out to give the hanger the proper offset. The offset is pressed into shape and the material raised to the upper part of the former. The "U" shaped former which is attached to the piston comes up and bends the hanger to the proper shape on the stationary former which is bolted to the macine.

Jig for finishing rod brasses

By E. A. Miller

THE drawing shows a jig designed to be used on a shaper table when finishing the channels of driving boxes to fit the rods. It consists essentially of a cast iron angle plate with a rib to fit in the bolt slot of the table. The angle plate has a ring 7 in. inside and 10 in. outside diameter protruding from the side ½ in. The face plate *B* is made in the shape of a disc 12 in. in diameter and has a recess bored 9/16 in. deep in the face into which the protruding ring of the angle plate fits. This ring has four holes drilled as shown in the drawing and reamed for a No. 10 taper pin. One hole is drilled in the angle plate to permit the taper pin to be inserted through the angle plate into the face plate. Care must be taken when drilling and reaming the dowel pin holes to have all the holes in the ring fit square with the hole in the angle plate so that the pin will provide the same spacing for all four positions.



Jig used on a shaper table for machining the channels of rod brasses to fit the rods

Referring to the arrangement drawing, after the top side of the box has been finished, the dowel pin is removed, the box is rotated 90 deg. on the bolt *D* and the dowel pin is inserted again. After the side of the box has been finished to fit the rod, the pin is again removed and the box is rotated to position for machining the other side.

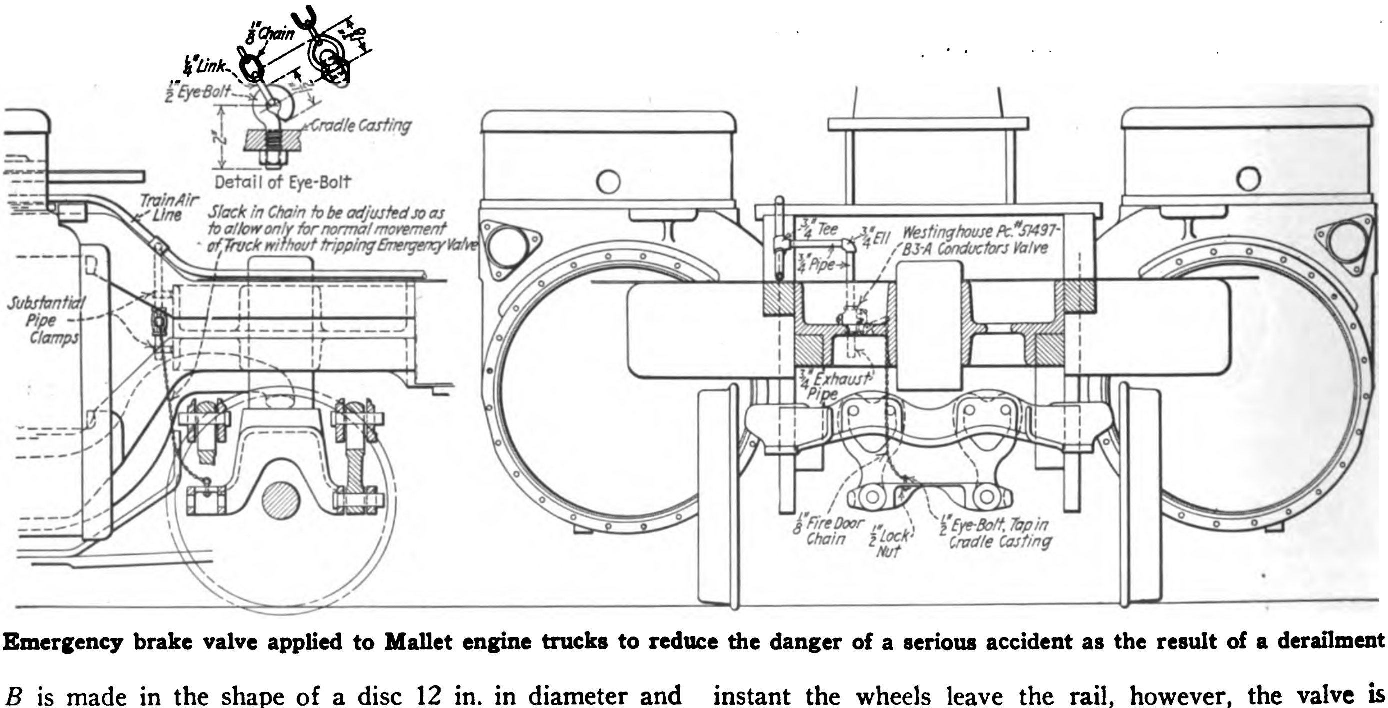
This type of jig, only of smaller construction, can also be used for front end brasses that have been made in halves and sweated together.

Emergency brake for Mallet engine trucks

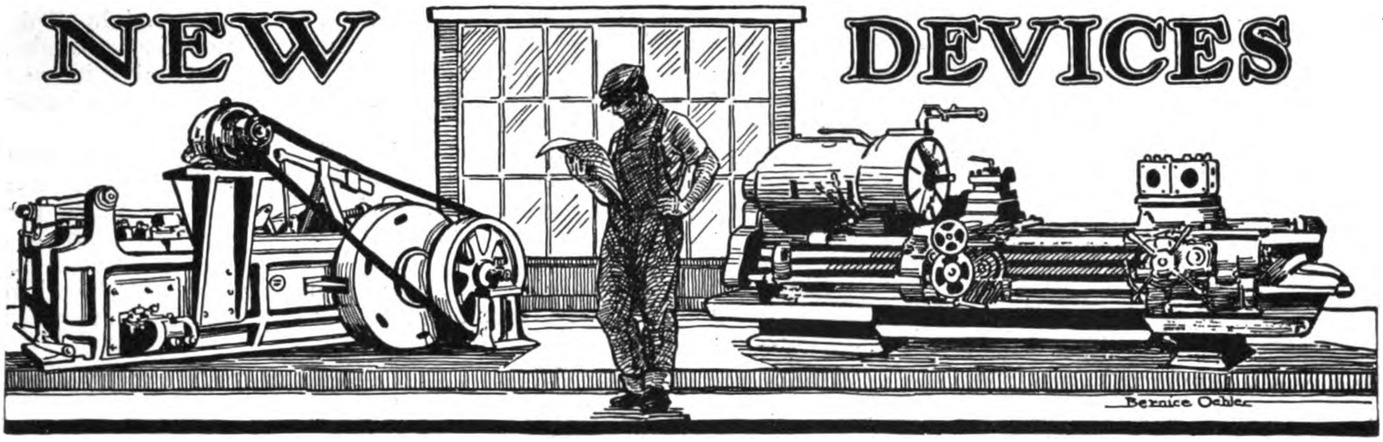
By H. C. Gillespie

Master mechanic, Chesapeake & Ohio, Huntington, W. Va.

IT is usually a difficult matter for an engineman running a Mallet type locomotive to detect the derailment of an engine truck. Sometimes when such derailments occur, the locomotive will be run for miles with the engine truck wheels on the ground unless they strike a cross-over or switch. When this happens, the entire locomotive is sometimes derailed with a possibility of a serious accident. In order to eliminate this danger, an emergency brake valve has been developed on the Chesapeake & Ohio which is to be applied to all Mallet locomotives. The operation of this emergency valve is simple. It consists essentially of a Westinghouse conductor's valve which is connected by a ⅛-in. fire-door chain to the engine truck rocker connecting link. The slack of the chain is adjusted to allow for normal movement of the truck without tripping the emergency valve. The instant the wheels leave the rail, however, the valve is pulled open by the chain which results in setting the brakes.

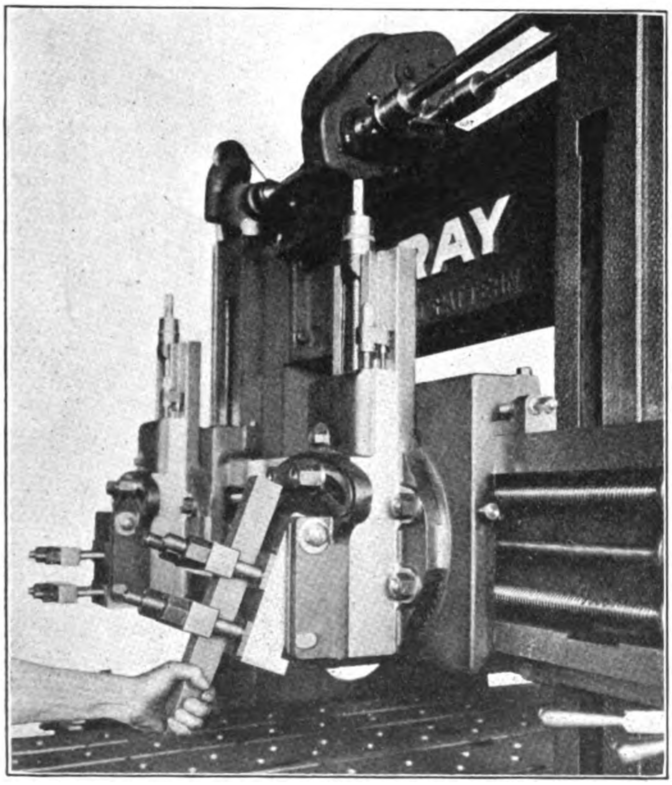


Emergency brake valve applied to Mallet engine trucks to reduce the danger of a serious accident as the result of a derailment



Openside planer with simplified control

AN openside planer built in 36-in., 42-in., 48-in., and 60-in. sizes has been recently placed on the market by the G. H. Gray Company, Cincinnati, Ohio. Recognizing the fact that openside planers are often used for very heavy work, and are therefore subjected to heavy cutting strains, the usual design of the column and knee has been departed from in order to make these parts heavy, and of unusually rigid proportions.



Head of the Gray planer showing the abutment apron and the twin-purpose taper gibs

This is evident from the fact that a 36-in. planer of this type has taken cuts with 3/16-in. feed, 1 in. deep in forged steel.

As the column is subjected to severe twisting strains it has been made triangular in section. Such a column is stiffer than the usual column of rectangular section because its walls are directly in line with the forces to be resisted, and there can be no yielding at the corners. A wide column face provides adequate support for the side head, even when long-reach tools are used. Heavy internal braces cast integral with the column add to its rigidity.

The bed of this machine not only has four vertical walls but is cast solid across the bottom under the gears and a heavy brace runs across the top of the bed directly under the cutting tools and the rail. This rigid structure eliminates vibration at this important point in the machine. The remainder of the bed is cast solid on top. The bed is planed on the bottom for ease of leveling and to relieve internal strains in the casting.

The heavy outer wall of the bed extends up on the side of the column to the level of the top of the table so as to support the column as high up and as near to the rail as possible. In addition a heavy tongue and groove, planed into the column and bed, with a metal-to-metal fit, fastens the column and bed together. No part of the bed or the drive mechanism extends below the floor-line, thereby making it possible to install the planer without providing special pits for the gear train or drive mechanism.

The gear train is similar to the helical gear train which has for years been a part of the Gray Maximum service planer. The gears and table rack are cut from steel forgings. They are helical throughout, including the bull gear and table rack, assuring the smoothness and the strength of the helical tooth.

A novel feature is the design of the bull gear which offsets the pressure of the tools on the work by exerting a side thrust on the table. The tools are usually fed away from the operator so that he can see the surface resulting from the cut, and the bull gear tends to push the table in the opposite direction. This materially decreases the tendency of the table to lift under a heavy cut. To still further reduce it, the bull gear teeth are designed with a nine degree pressure angle, so that the force exerted is very nearly horizontal, eliminating the usual vertical thrust. The Gray tooth form also provides a maximum of action in the arc of recess, rather than in the arc of approach, the teeth being of true involute form with long addendum pinions. The continuous rolling contact thus assured is not only of importance in getting fine finishing cuts but also ensures a steady flow of power for the heavy roughing cuts.

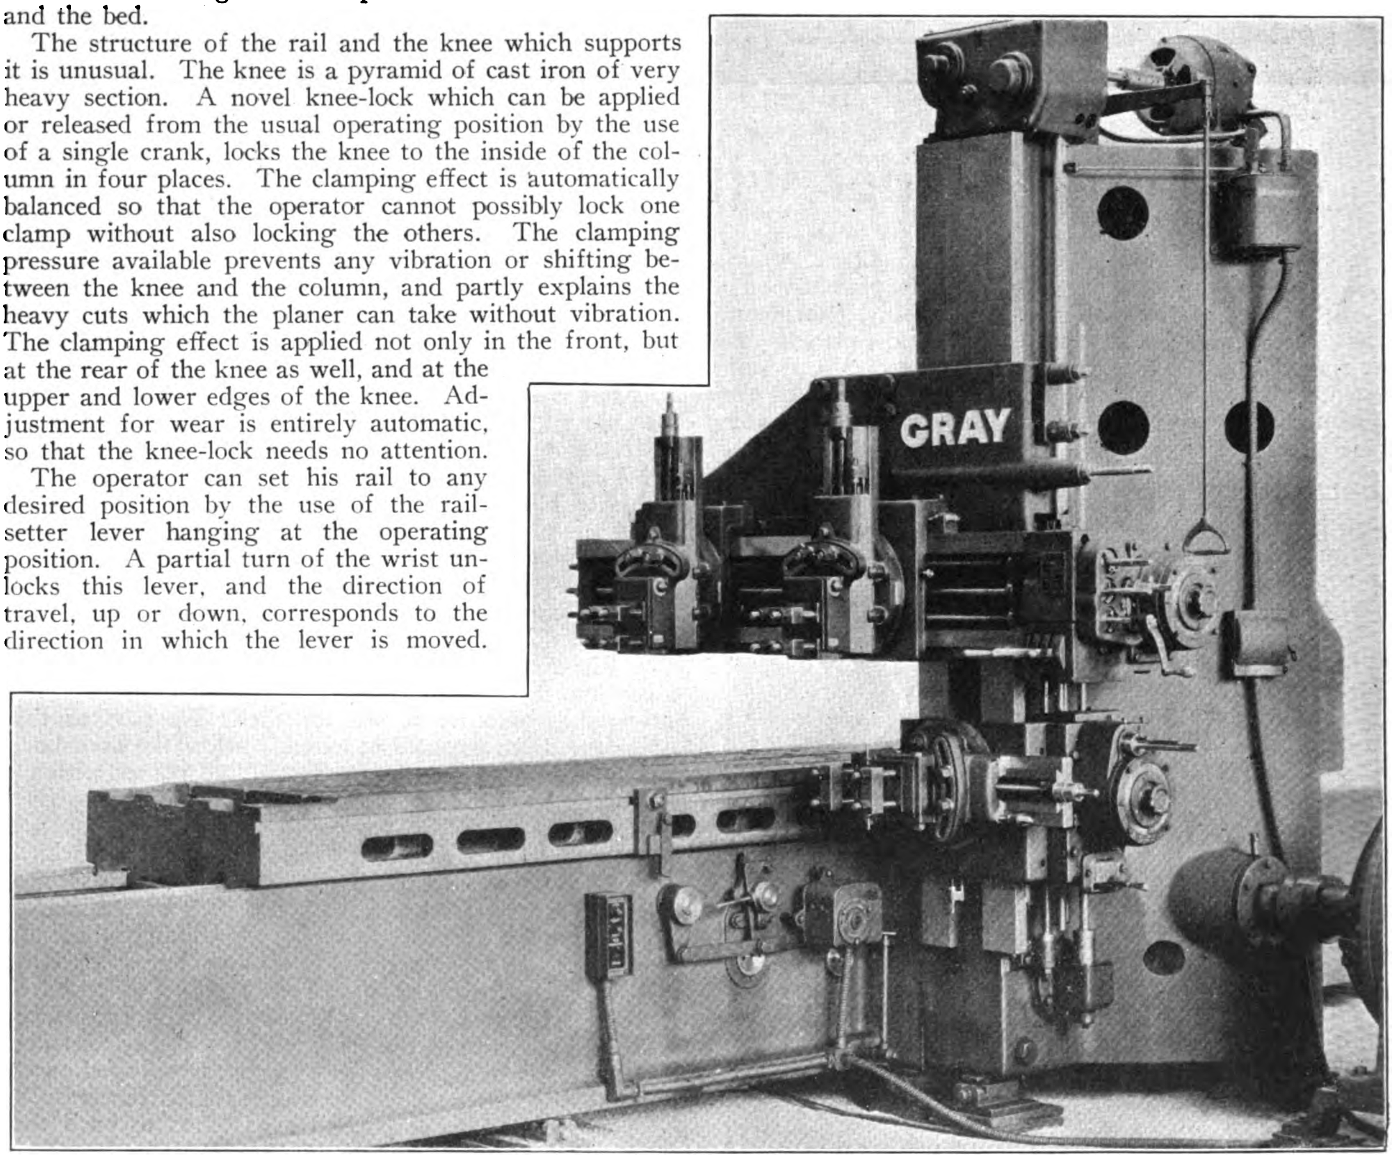
The gear train runs in a bath of filtered oil, and the side thrust bearings of bronze provided on each shaft in a flood of oil, as the upward pressure on the gib may, at bearings. This cascade of oil reduces the wear on the

driving train and cushions the teeth of the gear trains.

The necessity of planing overhanging castings of awkward proportions has induced the builder to provide hold-down gibs not merely at the center of the stroke, but over the entire length of the bed and table. Thus, tilting is prevented in any position of the table. The oil pumped to each V flows over the hold-down gibs, so that they run in a flood of oil, as the upward pressure on the gib may, at times, be almost as great as the downward pressure normally exerted on the vees. If it is necessary to remove the table, these gibs can be disengaged from the table without running it off the bull gear. Automatically oiled side thrust bearings are also provided between the table and the bed.

The structure of the rail and the knee which supports it is unusual. The knee is a pyramid of cast iron of very heavy section. A novel knee-lock which can be applied or released from the usual operating position by the use of a single crank, locks the knee to the inside of the column in four places. The clamping effect is automatically balanced so that the operator cannot possibly lock one clamp without also locking the others. The clamping pressure available prevents any vibration or shifting between the knee and the column, and partly explains the heavy cuts which the planer can take without vibration. The clamping effect is applied not only in the front, but at the rear of the knee as well, and at the upper and lower edges of the knee. Adjustment for wear is entirely automatic, so that the knee-lock needs no attention.

The operator can set his rail to any desired position by the use of the rail-setter lever hanging at the operating position. A partial turn of the wrist unlocks this lever, and the direction of travel, up or down, corresponds to the direction in which the lever is moved.



Front view of the Gray openside planer—all controls are centered in the right end of the rail, although a tumbler lever is provided on the other side of the bed for emergency use

As the rail does not drift when the lever is pushed into the "off" position, the operator can set it to a line and is encouraged to bring it down close to the work. This eliminates the tendency to take a long reach with the cutting tool, and enables the operator to take heavier cuts, and produce work free of chatter marks.

An entirely new device on this type of planer is the Gray ball bearing, spring counterbalance. A ball-bearing roller is mounted at the right hand end of the rail at the top. Heavy springs force this roller against the right hand edge of the column face, thereby keeping the rail and knee snug against the column even when unclamped. This counterbalance offsets the overhung weight of the knee, relieves the rail-elevating screw of binding strains, eliminates cocking and binding, and thus makes it easier to raise and lower the knee and rail, in spite of their massive proportions.

To set a head into place, the operator need only give one push to the rapid traverse lever. These levers are mounted in the right hand end of the rail, and this one motion of the lever suffices to start the motor in the right direction, disconnect the crank to avoid accident, and disconnect the feed mechanism. Putting the lever back into the "off" position automatically reconnects the power feed to the head and reconnects the manual crank. By this control the operator can quickly jump over an air gap in his job without "cutting air" for several strokes with the power feed. One rail head can be moved into place while the other is cutting, without interference. Similarly the slides can be moved up and down by rapid traverse. The Gray safety clutch disconnects the traverse motor and relieves the mechanism of all strains in case one head strikes another, or if the slide, in being moved downwards, goes too far, so that the tool strikes the bed of the table or the work.

The side head, when furnished, has its own rapid tra-

verse lever which is entirely independent from those provided on the rail. It also has its own feed dial.

On these planers the tool aprons are provided with an abutment or shoulder across the lower end. This prevents springing of the apron under the strain of clamping the tool. It bears against a corresponding surface on the lower end of the tool box, so that the upward thrust of the cutting tools comes on this abutment and not on the taper pin.

The table is of box-section, with heavy internal walls. One of these walls runs the full length of the table directly under the center T-slot, so as to tie the top and bottom plates together and prevent springing. This provision is supplemented by the double length bed; the table never overhangs, even at the extreme end of a stroke.

The "Cantslip" feed is a positive feed, not being transmitted through frictions. This ensures that the operator will get exactly the feed for which he has set the dial. The dial is self-locking, and is graduated in thousandths of an inch. A partial turn of the wrist automatically unlocks the dial and permits it to turn to any desired feed between zero and one inch, in steps of .01 in. The same type of feed is provided on the side head. A safety clutch instantly relieves the mechanism of strain should one head be allowed to feed into the end of the rail, or against the other head.

On this planer the oiling has been made as automatic as possible, not only by a continuous flow of oil to the V's, side thrust bearings, hold down gibs, gear train and shaft bearings, but by the provision of centralized oilers on the rail, rail heads, side head and column. The traverse motor requires no attention, as it runs on ball bearings in grease and drives the gears which run sealed in an oil case, mounted on ball bearings. It is recommended that the centralized oilers be filled once a week, a task that requires only five minutes. The oil under the gears, which passes through a filter, strainer and settling basin on each journey through the machine, need never be removed as it is automatically clarified and cleaned. The dirt taken out of the oiling system gathers in a pocket at the end of the bed, conveniently located for cleaning out.

The machines can be arranged for self-contained countershaft drive, motor drive with motor mounted directly on the column, or for reversing motor drive.

Wheel dog for changing journal brasses

In order to replace the bearing in a hot journal box some way must be found to hold the wheel firmly to the rail. The wheel is generally held down either by placing blocks or wedges between the top of the wheel and the bottom of the car, or by first jacking up the body and then forcing the wheel back down on the rail by means of a piece of timber used as a pry. This method requires an excessive amount of time and labor.

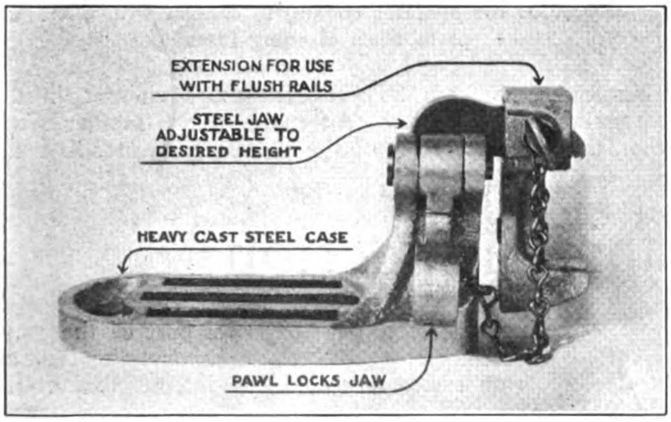


Fig. 1—Wheel dog with extension jaw in place ready for use when the rail is flush with the roadbed

The device shown in the illustration provides a means of effectively holding the wheel to the rail without the necessity of using any blocking whatever. It consists of a heavy steel base and upright to which is attached a drop forged steel jaw adjustable to any desired height and a pawl which locks the jaws in place after the load has been applied. An extension, which is used when the rail is flush with the roadbed is attached to the base by means of a small light chain so that it will not be lost.

Fig. 1 shows the device assembled to be used when the rail is flush with the surface of the roadbed. The end of the extension rests on the flange of the wheel. When the weight is removed from the brass by means of a jack which rests on the base of the wheel dog, the pressure exerted by the jack on the device prevents the wheel from leaving the rail. Thus, in a comparatively short time the weight is removed from the brass to permit its renewal without the necessity of securing blocking to keep the wheel to the rail.

Fig. 2 shows how the device is used when the rail is above the surface of the roadbed. The adjustable steel jaw grips the flange of the wheel and when the load is applied to the base of the device the wheel is firmly held to the rail.

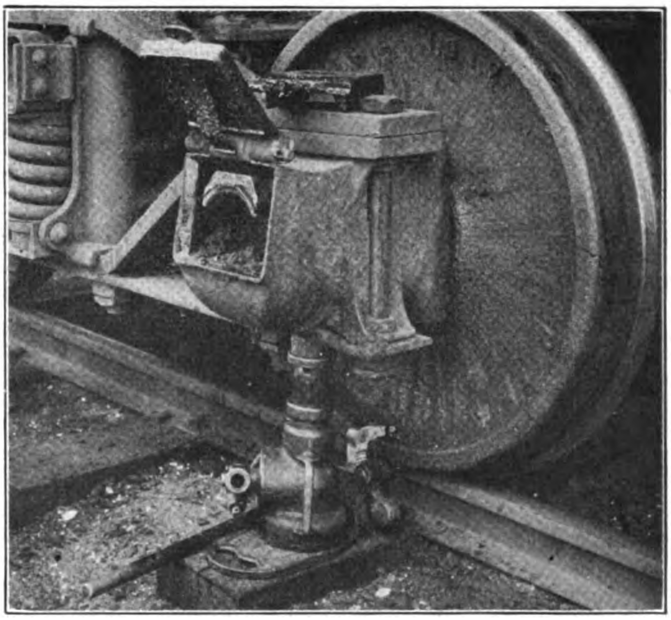

Fig. 2—Journal box jacked up off of the axle—The adjustable jaw has kept the wheel on the rail

This device can be used to advantage by car and locomotive tender repairmen and by train crews. It is manufactured by the Railroad Wheel Dog Company, Provident Building, Tacoma, Wash.

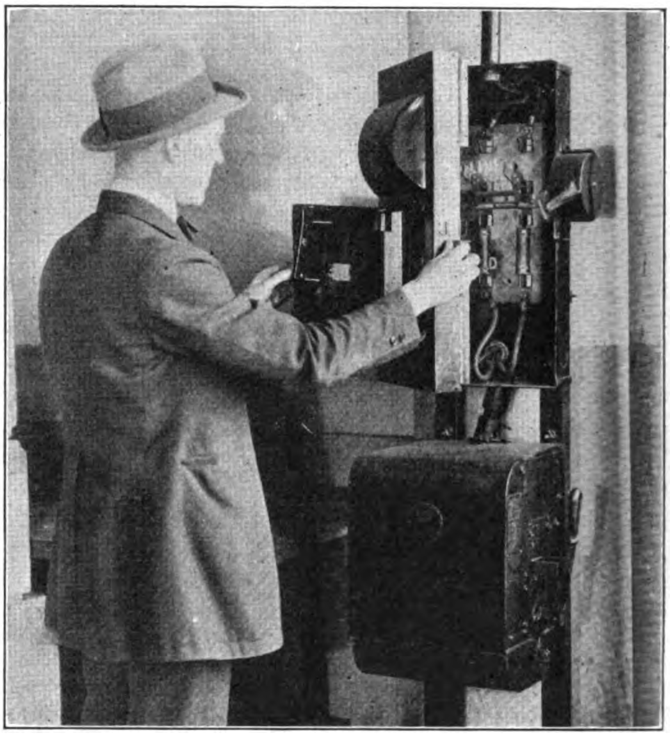
Safety switch which protects operator and motor

A SAFETY switch known as the WK-55 has been introduced by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., the design of which provides full safety for the operator and the motor under all conditions.

In order to eliminate the possibility of the operator coming in contact with live parts when changing fuses, the switch has been designed with a double door construction. Within the main door of the switch is a smaller door giving access to the fuse compartment. This fuse compartment door is interlocked with the operating handle in such a way that it will not open until the switch is thrown to the off position. In this position, even with the door open no live parts are accessible and as long as the door remains open the switch cannot be thrown on. The outer door covering the entire switch enclosure is designed for padlocking so that it can be opened only by an authorized person. This door can be opened for inspection and testing without interrupting the service.

The design of a new "make and break" mechanism, entirely contained in the operating handle outside of the cabinet, does away with the possibility of failure of the switch box to function properly, which would produce dangerous short circuit hazards. This design removes the danger of loose parts coming in contact with current carrying parts of the switch and leaves more space for wiring.

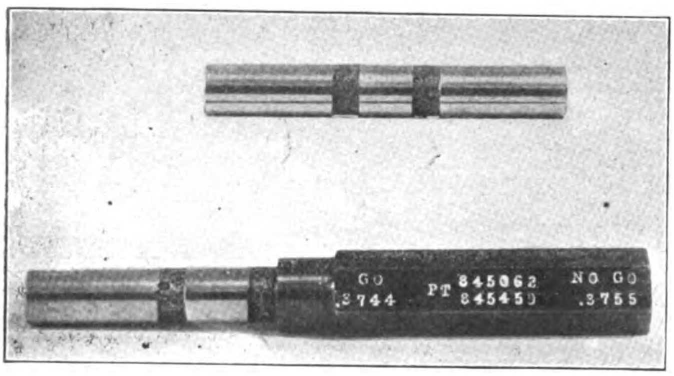
An arc quencher of simple design has been developed that serves to extinguish the arc quickly and efficiently when the circuit is opened. It consists of metal laminations, separated by layers of insulation and air space. As the blade traverses the quencher, the arc is broken into a series of sparks that are cooled by the metal plates and by the air currents between them. As the blade passes through the quencher, the arc is dissipated and cooled to such an extent that the current drops to zero and the circuit is interrupted without danger or damage. The arc quencher is capable of breaking circuits carrying from 50 per cent more current in the larger sizes to 300 per cent more in the smaller sizes, than the rated amperes of the switch, even at 500 volts.



Westinghouse safety switch provided with a double door to prevent the operator coming in contact with live parts when cleaning fuses

Plug gage for rapid inspection

THE present day tendencies among the railroads is to work to closer limits. This requires more careful inspection and the use of various types of gages. The plug gage is being used to advantage to keep the work within the allowable tolerance. A new type of plug gage has been placed on the market by the Van Keuren Company, Watertown, Mass., which is designed to permit of rapid inspection.



Plug gage designed to give maximum service

The gaging unit, which is the novel part of the gage, is shown in the upper part of the accompanying illustration. It has on each end a "go" gaging member of the desired length, usually about 1 in., and in the center is a "no go" gaging member about 3/8 in. long. As the "go" member is the one which enters the hole and is subject to the most wear, this gage provides a maximum of wearing surface.

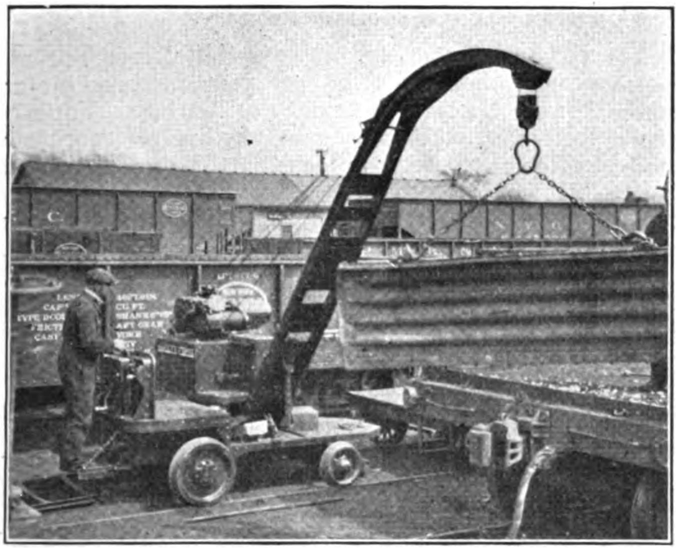
The plug gage unit is set in a handle as shown, being firmly cemented with stick shellac. The shellac protects the "go" member in the handle from corrosion, while the other end of the gage is being used. When one end is worn undersize, the gaging unit is reversed and thus a double life is secured. Sizes larger than 1/2 in. diameter may be used without a handle.

The gaging unit is made of a high grade tool steel selected for its wearing qualities and permanency. The steel is carefully hardened, thoroughly seasoned and the surfaces are lapped to a high finish.

These gages can be furnished to an accuracy of .00004 in., this accuracy being secured by light-wave measurement. Most plug gages have a wear allowance of about .0002 in. and the advantage of an accurate plug gage for tolerance work is that the gages may be kept close to the high limit.

A new tool for car repair work

Many portable electric cranes of the battery driven, four-wheel steering type built by The Elwell-Parker Electric Company, Cleveland, O., are used in locomotive repair shops, stores departments and engine houses. To satisfy a demand to extend the work of these units beyond the planked platforms and concrete runways, a new type is now offered the car repair department. This unit, running on standard gage track, will pick up deliveries at the shop or in the yard and deliver them alongside or actually place the piece on the car ready for bolting or riveting. It is serving as a dismantler of cars as well as an assembler and gathers scrap or waste material which it places on the pile or in the scrap car.



Portable electric track crane handling corrugated steel car ends

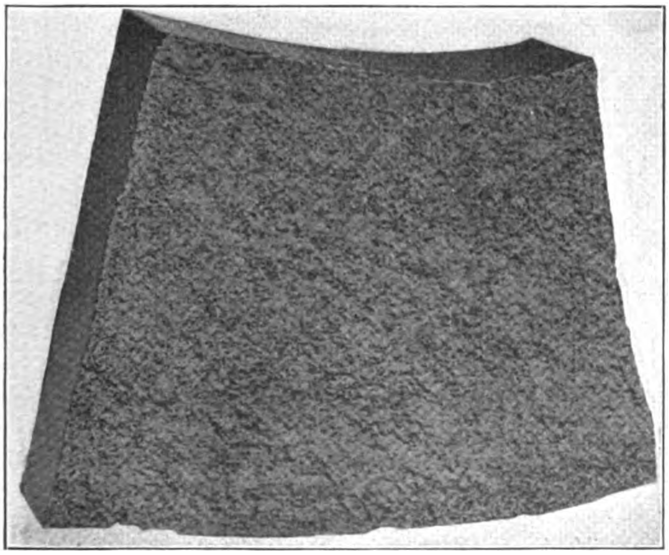
The crane consists of standardized units used on the floor type crane. Special heavy steel axles with good clearances beneath, fitting the standard gage rail track, are employed. The wheel base of the cranes is practically the same as most hand pushed cars and they use the same turntables as the latter.

The crane boom is of the telescopic type and of such length as to reach over the middle of a car on the adjacent track. The upper end of the boom is so curved that it clears the side of a gondola car 11 ft. above the rail. The operator retains his driving position on the tructor pedals when hoisting, raising or lowering the boom or when slewing it through 180 deg. from the right to the left track. All operations are by electric motor but the slewing may be effected by either hand or motor mechanism as specified.

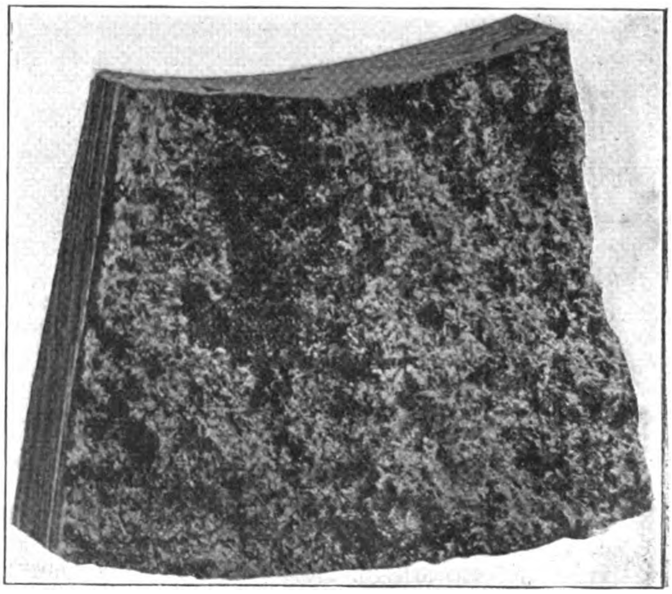
The outfit weighs approximately 7,000 lb. when fully equipped. It handles any load up to 3,000 lb. which brings within its range 90 per cent of the parts handled in car repair work. A crane on each third track serving cars on either side can do practically all the lifting and material handling, thus saving the use of the heavy locomotive type crane for work better suited to its capacity. The standard Elwell-Parker safety controls of power and brake are used throughout on this equipment.

Locomotive bronze crown bearings

When bronze crown bearings are cast in sand molds more or less trouble is experienced with sand in the surfaces which makes them difficult to machine, and with sand or blow holes in the body of the casting which cause many brasses to be thrown away before they have worn down to the wear limit. In an effort to overcome this difficulty, the More-Jones Brass & Metal Company, St. Louis, Mo., has adopted the practice of casting crown brasses in metal molds. This method is not entirely new but improvements have been developed by this company for which it has obtained patents.



Specimen of crown brass cast in a metal mold



Specimen of crown brass cast in a sand mold

An exhaustive comparative test has been made of bronze bearings cast in a chill and sand mold, the metal used being poured from the same pot. The results of these tests are shown below:

Chemical analysis

	Sand mold, per cent	Chill mold, per cent
Copper	72.70	72.55
Tin	7.10	7.15
Lead	18.80	18.95
Zinc and impurities	1.20	1.20
Phosphorus	.05	.05
Undetermined	.10	.10
	100.00	100.00
Brinnel hardness number	51	62
Tensile strength, 2 in. standard test bar	20,500 lb. per sq. in.	29,500 lb. per sq. in.
Elongation in 2 in., per cent	9.0	15.5
Elastic limit in compression (load necessary to produce a permanent deflection of .001 when applied to a 1-in. cube	11,800 lb. sq. in.	15.500 lb. sq. in.
Permanent deflection under load of 65,000 lb. per sq. in. when applied to a 1-in. cube	.28 in.	.16 in.

Transverse bending tests

Specimens 1 in. cross section; distance between supports, 10 in.; load applied at center.

Load, lb.	Vertical deflection, in. Sand mold	Chill mold
500	.013	.009
1,000	.035	.026
1,600	.063	.047
2,300	.340	.140
2,400	Specimen failed	.175
2,750		.300
3,200		.405
3,600		.520*

*Specimen started to fail.

The tests show that the pressure chilled cast bearings possess approximately a 50 per cent increase in the physical properties over the sand cast bearings. Furthermore, the chilled mold casting weighs five per cent more per cubic inch because of its density. The increased load factor and strength, due to the density of the pressure chilled cast bearing, are not the only real improvements; the pressure chilled cast bearings are free from sand, grit, oxidization and impurities.

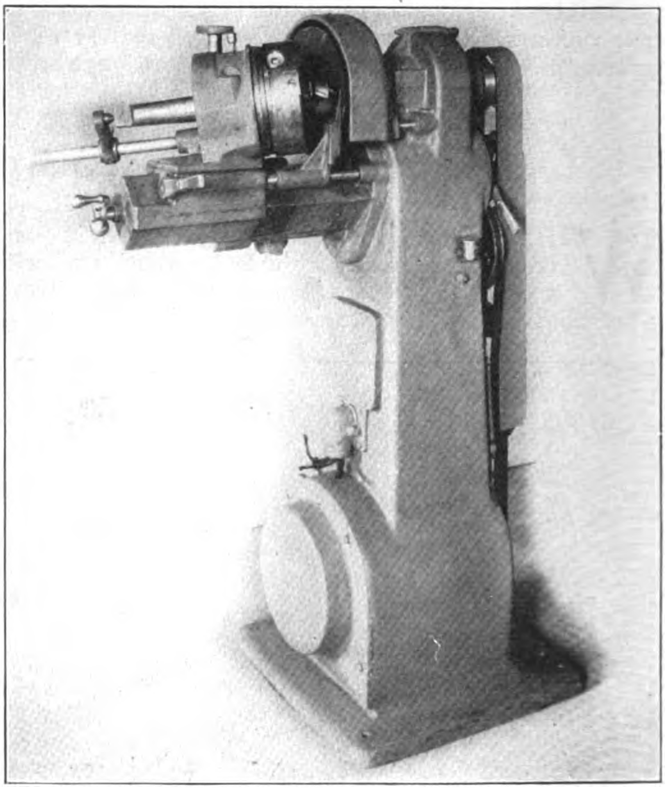
Oliver automatic drill pointer

THE efficiency of twist drills is largely dependent on proper grinding. If the clearance of a drill is insufficient or imperfect, it will not cut. When force is applied, it resists the power of the drilling machine and is crushed or split. It requires considerable skill on the part of a machinist to grind a drill so that the cutting edges have a proper and uniform angle with the longitudinal axis of the drill, having them of exactly equal length and the lips of the drill sufficiently backed off or cleared. In order to overcome this difficulty, the Oliver Instrument Company, Adrian, Mich., has had on the market for a number of years an automatic drill pointer designed to provide accuracy for this kind of work. The motions of grinding a drill are entirely automatic and are produced by fixed mechanisms. The drill is held in the machine in the same manner that it is held in a drill press. It is rotated automatically, stopping momentarily as each cutting lip is presented to the grinding wheel. The grinding wheel has two motions, one an oscillating motion which carries the wheel across the cutting edge of the drill; the other motion advancing the grinding wheel toward the drill as the drill revolves, the combined motions being such that a clearance is formed, the angle of which increases toward the center as is necessary for proper drilling. The operation of the machine depends in no way on the experience or skill of the operator. There are no adjustments on the machine and every type and size of drill is set exactly the same.

An improved design of this machine has recently been brought out. The grinding wheel on the old machine was carried in a rocker arm which oscillated across the point of the drill. It also had an end or axial motion which advanced the grinding wheel toward the drill as the drill revolved, producing the proper increase in clearance as the center of the chisel point of the drill was reached. Referring to the illustration, the new construction eliminates the rocker arm and the oscillating motion is obtained by the revolving of the wheel spindle in a quill, which has an eccentric motion. A cam operates the forward and backward motion of the quill, the same as in the old machine, but the new design has eliminated the universal shaft and joint.

Grinding is secured with a continuous fixed automatic multiple motion, producing a clearance, the angle of which increases toward the center as is necessary for proper drilling. The grinding wheel is thus given two motions in a manner similar to that described for the old machine. Both lips are ground with the same angle which insures the web being central, thus enabling bent drills to be ground accurately. Any practical combination of clearance angle, chisel point angle and drill point angle can be secured.

The chuck head is one of the new features which



An automatic drill pointer designed to produce a theoretically correct point

permits the holding of drills at the point instead of at the shank. The drill holding chuck can be perfectly centered or set for grinding off center as desired. This construction does not permit the changing of the point angle. Where this is desired, the manufacturers supply a chuck equipped with a universal head which holds

drills by the shank in a manner similar to the old machine. The new construction gives a continuous motion to the drill which increases the grinding speed about 50 per cent over that of the old type. The clearance cam being concentric with the wheel spindle eliminates possibility of lost motion between the cam and the drill.

A feature of the new machine is the elimination of the need of cooling water. There are two reasons for this. First, the direction of grinding tends to carry the heat away from the cutting edge of the drill. Second, the grinding of the drill while it is revolving presents each lip to the wheel momentarily, thus giving the heat a chance to be carried away from the edge while the next edge is coming in contact with the wheel. This permits the feeding of the drill as rapidly as the strength of the wheel will permit. It is claimed that with the addition of water, the speed of grinding could not be materially increased.

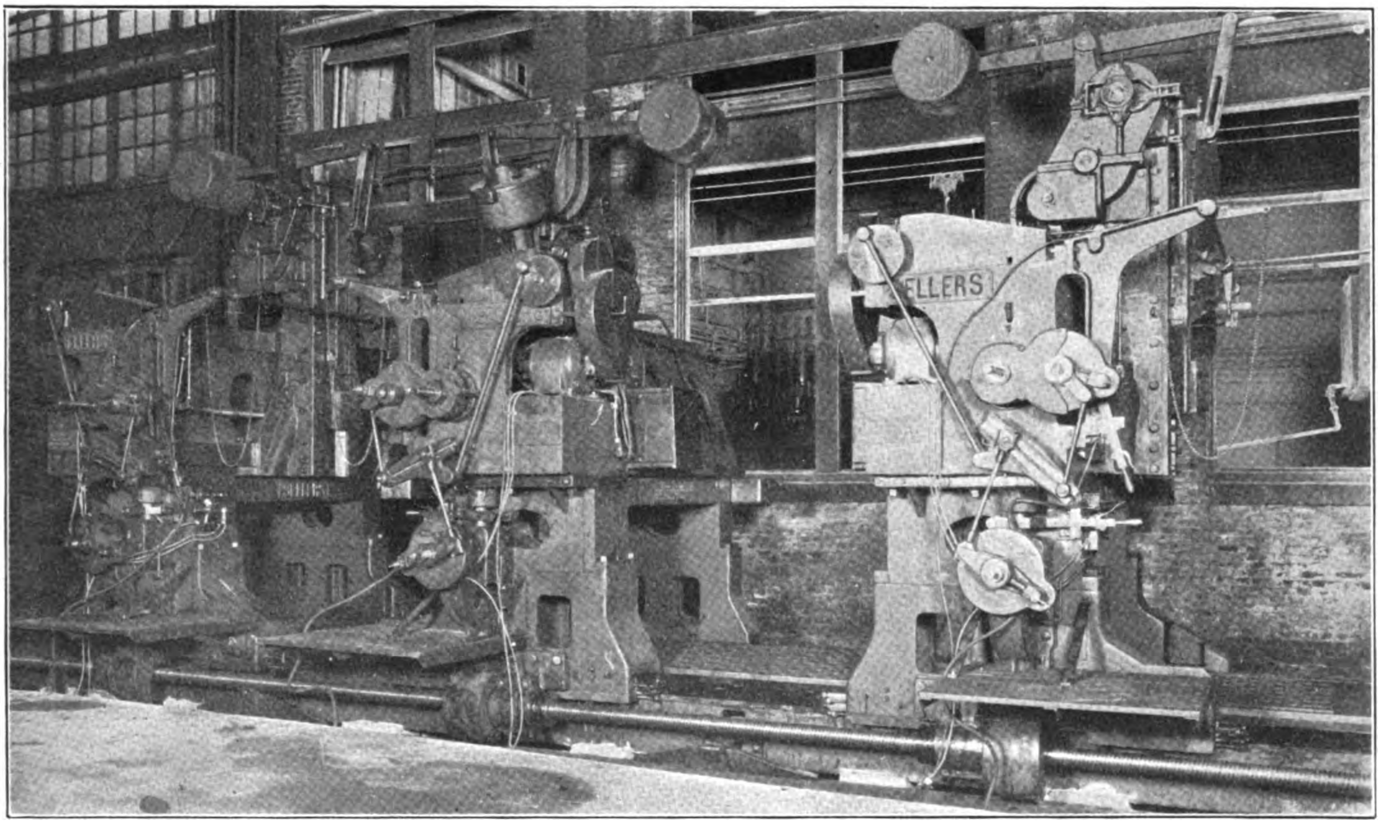
The Oliver automatic drill pointer is supplied in various sizes, one of which has a capacity up to 1½ in.; one a capacity up to 3 in., and a small type machine, a capacity from the smallest up to ½ in. and for two flute drills only. The larger machines are adjustable for either two, three or four flute drills.

Triple head locomotive frame slotter

A FRAME slotter has been designed and built by Wm. Sellers & Company, Inc., Philadelphia, Pa., to meet the requirements of constantly increasing sizes of locomotive side frames. While the machine is based on the best features of the smaller size Sellers frame slotters, it incorporates the advantages of the Sellers spiral pinion planer drive and improved reversing planer motor and control apparatus.

The machine consists of a heavy bed furnished with convenient bolt slots and supporting three slotting heads. The latter are moved by means of revolving nuts and a single screw extending along one side of the bed. They are guided by one upright with a relatively long bearing on the bed. The screw is stationary and therefore always kept in tension. As the bed is over 60 ft. long, the screw is provided with tumbler bearings which automatically move out of the way as the head approaches.

Each head consists of a substantial crossrail supported on two uprights or legs. The face of this crossrail is 3 ft. 10 in. from top to bottom and the depth of the rail is 3 ft. 5½ in. at the lower end and 2 ft. 5½ in. at the top. The uprights or legs of the cross head each have a bearing on the bed of 6 ft. 6 in. in length. The width of the main upright, which is used for guiding, is 16 in. and the width of the other is 10 in. The uprights are 5 ft. apart, giving ample dimensions on each side of the largest frame made. The height under the cross rail is 42 in. which is sufficient to allow four 9-in. frames to be slotted at one setting. The cross rail may be swivelled by a ratchet to 6 deg. on each side, allowing for the angular surfaces of the frames.



The Sellers triple head frame slotter

A saddle or slotting head of new design is mounted on each cross rail and provided with 5 ft. 3 in. of travel by means of a screw along the rail. Adjustable taper gibs are provided to take up the wear between the saddle and the rail.

Probably the most noteworthy feature of the slotting head is the method of driving the slotting bar. The

Sellers spiral pinion planer drive is used for this purpose. The driving shaft is actuated from the reversing motor through only two pairs of gears, one of which has herringbone teeth. Variations in the speed of the slotting bar are easily obtained by varying the motor speed with field rheostats. Cutting speeds of 25 to 50 ft. per min. are provided and return speeds of 50 to 75 ft. per minute. Speeds faster than these could be easily obtained, but are not found to be profitable when used with short strokes.

It is interesting to note that one difference between a crank driven slotter and a reversing motor driven slotter is that on the former the cutting speed varies from zero at each end to a maximum speed at the middle of each stroke, while the reversing motor driven slotter keeps the cutting speed constant throughout the stroke except for the acceleration at the start, and deceleration at the end.

The ram is made of steel and is of box section 8 in. by 15 in. outside dimensions. It is 6 ft. long so that there is always sufficient bearing in the guide to take the pressure of the cut and prevent deflection at either end of the stroke. A shoe, adjustable by set screws, is provided at the side of the ram to take up wear, and to help maintain alinement. The ram is counterweighted and provided with a forged steel rack 5 in. wide. The guide for the ram is 7 ft. 6 in. long.

Each head is provided with an electric feed mechanism. It gives the advantages of simplicity, easy adjustment and accurate timing. It is set to take the minimum amount of stroke to perform the feed. Feeds of 1/64 in. to ¼ in. are provided in small increments. At the end of each stroke the feed motor, which is connected to the feed discs, is started and runs until it has driven the discs 180 deg. when it stops. The starting and stopping of the feed motor is arranged through the master switch reversed by the ram, by means of a special limit switch. The feed motor is started at each end of the stroke of the ram and as it only requires a few seconds to move the disc, it is arranged to start just before the end of the stroke, and thus divide the time of operation between the two strokes. This reduces to a minimum the amount of stroke required for feed. Moving the feed discs operates the crank and ratchet from which both motions are set for the proper amount of feed.

The traverse of the saddles on the crossrail and of the crossrail on the bed are obtained with the same motor that is used for the feed. The push button control enables an operator to set his tool so closely that it is not necessary to use the hand adjustment. The latter is provided, however, in case it is desired. The speed of travel of the saddle and crossrail is 4½ ft. per minute.

The machine is equipped with several safety devices. The ram is provided with a mechanical knockout at each end of the stroke which disconnects the driving gear from the ram and instantly applies a brake. This protection is not necessary but is desirable in case the operator fails to set the stops properly or in case the stops become loose. There are limit switches at either end of the travel of the saddle on the cross rail which prevent traversing or feeding too far in either direction. The feed and traverse are interlocked so that the traverse cannot be started with the feed clutch engaged and vice versa. Furthermore, the tool ram cannot be operated while traversing, as it is considered dangerous to have the two operating at the same time.

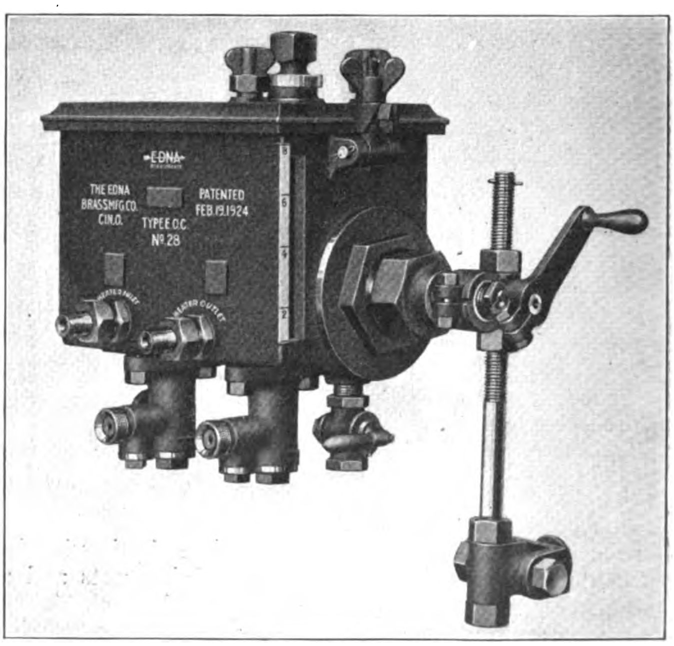
Locomotive force feed lubricator

A FORCED feed lubricator designed to meet railroad requirements has been placed on the market by the Edna Brass Manufacturing Company, Cincinnati, Ohio. It is made in five different sizes of two, three, four, five and six feeds with oil capacities of 8, 9, 10, 11 and 12 pints, respectively.

The body is equipped with sight glasses, one in each end, and a gage rod through the cover. Pint marks are stamped on the body. The lid is hinged. The lubricator can be used either right or left hand and to make the change requires only the reversing of the drive shaft and the lid. The drive is a fifty-tooth hardened steel ratchet and three pawls. The reverse ratchet is steel and is operated both by power from the locomotive and by hand. The forcing units consist of a hollow plunger and cylinder of steel, with brass and other metals suitable for their performance. The parts are immersed in oil at all times and require no attention. The discharge is made through the unit holder, equipped with two steel ball checks. The line check seat is steel hardened and ground. A second or intermediate ball check is used as added precaution against water leaking back to the lubricator.

In installing the lubricator, a suitable bracket ¾ in. thick should be provided with a length equal to that of the lubricator body and secured to a rigid part of the locomotive, preferably to studs in the back valve chamber head. Should conditions prevent, it can be placed elsewhere, but if it is not absolutely rigid, broken pipes may result. The terminal valves are provided with ½-in. standard pipe threads; these should be attached to tallow studs and can be set in any position.

The bodies of all the lubricators are equipped with heaters for a ⅜-in. steam pipe connection in which either live or exhaust steam can be used. If exhaust steam is



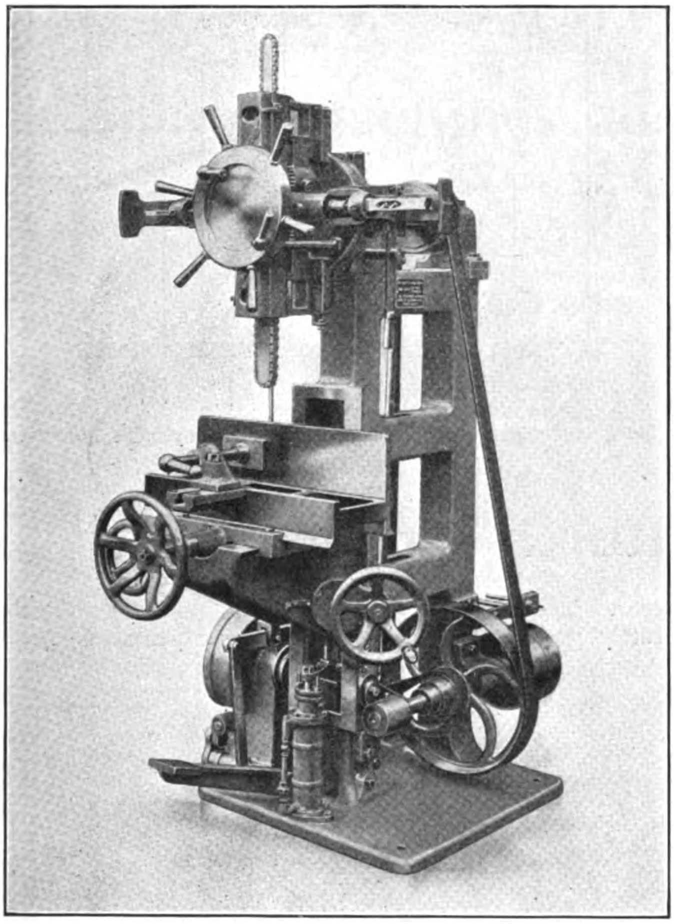
Force feed lubricator designed to prevent water from leaking back to the lubricator

used, it should be taken from the air pump exhaust. Precaution in piping must be taken to avoid water traps in

order to prevent freezing in cold weather. The terminal valves are set at 225 lb. pressure at the factory. This is sufficient in all cases where boiler pressure is lower than 210 lb; if a higher boiler pressure is carried, it will require the resetting of terminal valves to about 15 lb. higher than the boiler pressure.

Automatic chain and hollow chisel mortiser

In the past the chain and chisel mortisers manufactured by B. Smith & Son, Bingley, England, have been operated by hand levers. The drawback with these machines was principally with the chisel slide which could not produce a mortise hole larger than ⅝ in. square and to do this required a great amount of energy because it was necessary to broach a square hole as the boring augur did not bore a square hole. It had to be squared by the exertions of the operator. To overcome this undesirable feature, a full automatic chain and hollow chisel mortiser has been designed by the above manufacturer of machines of this type.



A square hole can be bored without any effort on the part of the operator

The body of the machine is in one piece and is of the open-column type which exposes every working part to the operator. The table has three positive ranges or travel to suit different size mortise holes. In the event of a chain breaking, there is a slipping clutch incorporated in the feed shaft mechanism which prevents any damage being done to either the tools or the machine. The table is fed up to the work by a rack and pinion. Mounted on the end of the pinion shaft is a large bronze work wheel and mounted directly underneath this wheel is a hardened worm running on the second gear shaft. This shaft is pivoted at its extreme end and on the operator pressing down the feed pedal this worm and shaft are raised into engagement with the large worm wheel and the table immediately begins to rise. On completion of the mortise, the operator simply releases the pedal which disengages the feed and the table descends rapidly but without shock or jar. The cushioning of the table on its return stroke is obtained through the action of a piston working inside a hydraulic cylinder.

A hand wheel is mounted on the right hand side of the saddle and by turning this wheel to the right the table is locked and held in any position after the foot has been removed from the feed treadle. This enables the slots to be cleaned out and when the table is required to descend, a quarter of a turn to the left of this hand wheel releases the table.

The drive is direct on to the main bottom shaft through the usual fast and loose pulleys and from this shaft a straight belt drives the top shaft upon which is mounted a friction clutch. This clutch is out of engagement when the table is at the bottom and in consequence the clutch spindle of the machine is stationary. When the operator presses down the foot pedal the table begins to ascend and a lever which is in engagement with the clutch and is held out of gear when the table at the bottom is then liberated, allowing the clutch spring to engage the loose portion of the clutch with the fixed, causing the clutch shaft to revolve. On completion of the mortise the table descends and on reaching the bottom, the clutch is automatically brought out of engagement, and the mortise chain cutter or hollow chisel comes to rest.

The turret mortise head is mounted upon a continuation of the top clutch shaft and carries four slides. There may be any combination of four different tools. As arranged, there is alternately a chisel slide and then a chain slide. Each of these slides carries either a complete attachment for driving a mortise chain or hollow chisel and they are mounted on ball bearings throughout. The end of the clutch shaft has mounted on it first, a straight spur wheel and then a bevel wheel. The spur wheel will engage with the chain slide and the bevel wheel with the hollow chisel slide. These slides are held out of engagement with a strong spring which is concealed within the slide, but upon the operator pulling the handle, which is mounted at the right of the machine, towards him, the turret is disengaged and can be revolved round in either direction. As each slide passes the bottom center, which is the working position, a fixed cam at the back of the turret engages with a roller fixed upon a stud and carried by each slide, causing the slide to be raised into gear with the wheel mounted upon the clutch slide, at the same time the turret automatically locks itself in this position and the cutting tool, whether chain or chisel, is in the correct cutting position. It will be clear from the above that only one tool is in engagement at one time and only this one is in rotation when the table is in motion. The turret can be swung round and any cutter brought into engagement without any risk to either the operator or the gears, because these are all stationary when the tools are being changed.

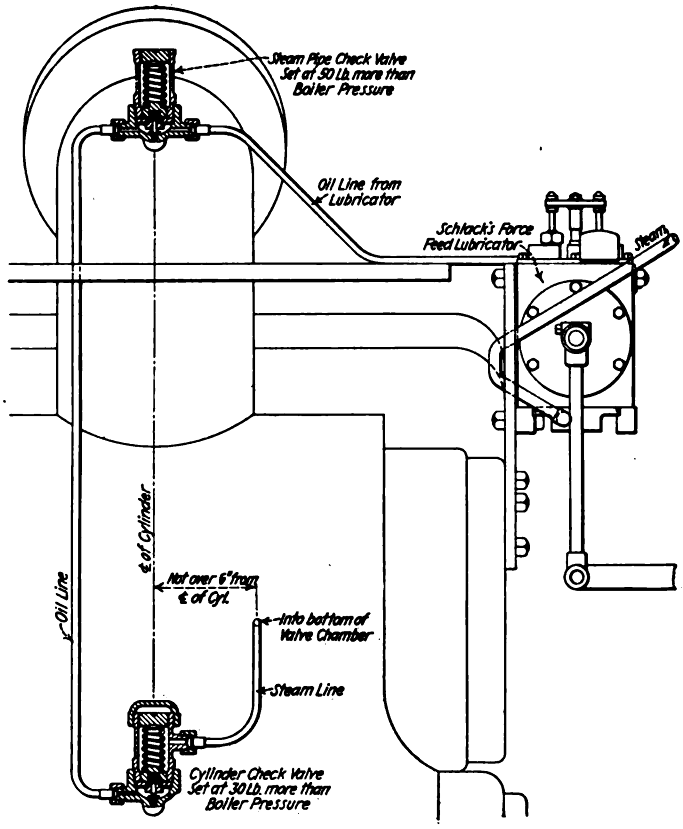
Schlack's force feed lubricator

With the system of alternate valve and cylinder lubrication for locomotives shown in the illustration, all of the oil is delivered into the steam pipe when the locomotive is working steam, but when the locomotive is drifting, all of the oil is delivered directly into the cylinders. In the alternate system there is a check valve in each cylinder in addition to a check valve in each steam pipe for each feed. The steam pipe check valve is set with a spring pressure to release at 300 lb. per sq. in. and has one oil inlet and two oil outlets. The cylinder check valve is set with a spring pressure to release at 250 lb. per sq. in. and has one oil inlet and one oil outlet and in addition has one steam inlet.

An oil pipe conveys the oil from the lubricator to the steam pipe check valve. Another oil pipe conveys the oil from the steam pipe check valve to the cylinder check valve. A steam pipe conveys the pressure from the pressure chamber of the main valve of the locomotive to the chamber on top of the diaphragm of the cylinder check valve.

When the locomotive is working steam, the steam pressure added to the spring pressure of 250 lb., the cylinder check valve holds the cylinder check valve spring to a higher oil pressure release than the steam pipe check valve with a spring pressure of 300 lb. The result is that all of the oil is injected into the steam pipe while the engine is working steam.

When the engine is drifting, the cylinder check valve is relieved of the steam pressure when the locomotive throttle is closed, so that it opens at the spring release pressure of 250 lb. This pressure being less than the spring release pressure of 300 lb. of the steam pipe check valve, all of the oil is injected directly into the cylinder. This lubricating system has been placed on the market by the United States Metallic Packing Company, Philadelphia, Pa.



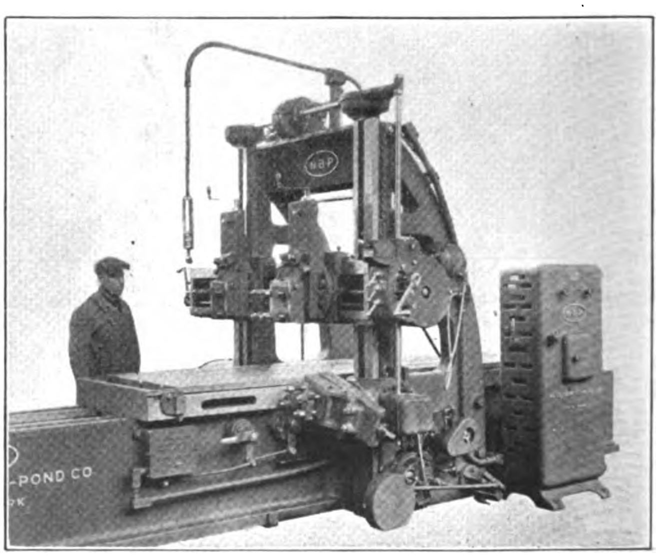
Piping arrangement for alternate valve and cylinder lubricator

Effective safety features for planers

An operator when setting up work on a planer often has part or all of his body between the work and the planer, and thus is in danger of injury by unintentional starting of the machine. Many planers afford absolutely no protection from this danger. A man may stumble against one of the control levers on either side of the bed, a passing truck may strike it, or it may be hooked by a swinging crane chain. A helper working around the machine and removing chips may move one of the control levers at any time, starting the planer suddenly and without warning.

It is possible to lock the control levers in the off position, but such locks are a source of danger, as they may become engaged while the planer is running. In this case some part of the reversing mechanism must break and the planer usually fails to reverse, running the table off the driving gear. Furthermore, it is well known that safety devices which require extra movements on the part of the operator are practically never used.

The master pendent switch, shown in the illustration, is designed to prevent such accidents. This is an important part of the electrical equipment furnished by the Niles-Bement-Pond Company, New York, on planers driven by direct connected reversing motors. A distinctive feature of this switch is that it may be used for instantly stopping the machine by pushing the handle upward. Operators make a practice of using it for this purpose because it can be reached more easily and quickly than the control lever. The planer cannot be started except by deliberately pulling down the handle of the pendent. Accidental starting is impossible and the operator is perfectly safe, no matter what happens to the control lever.



Location of the pendant switch in relation to the position of the operator

This switch may be used at any time without first throwing a distant transfer switch. Neither does the operator need to leave his position when resuming normal operation. The entire control of the table motion, starting, stopping, reversing or "jogging" by very small fractions of an inch is obtained by this switch. It is this feature which makes the master pendent so convenient and valuable as a safety device. The switch hangs by a flexible cable from a swivel on the arch or crosstie of the planer, permitting the operator to keep it in a location convenient to his working position. This makes it possible to stop the planer instantly in an emergecy, as the operator does not have to stoop and reach for the control lever, but simply hits the handle of the pendent.

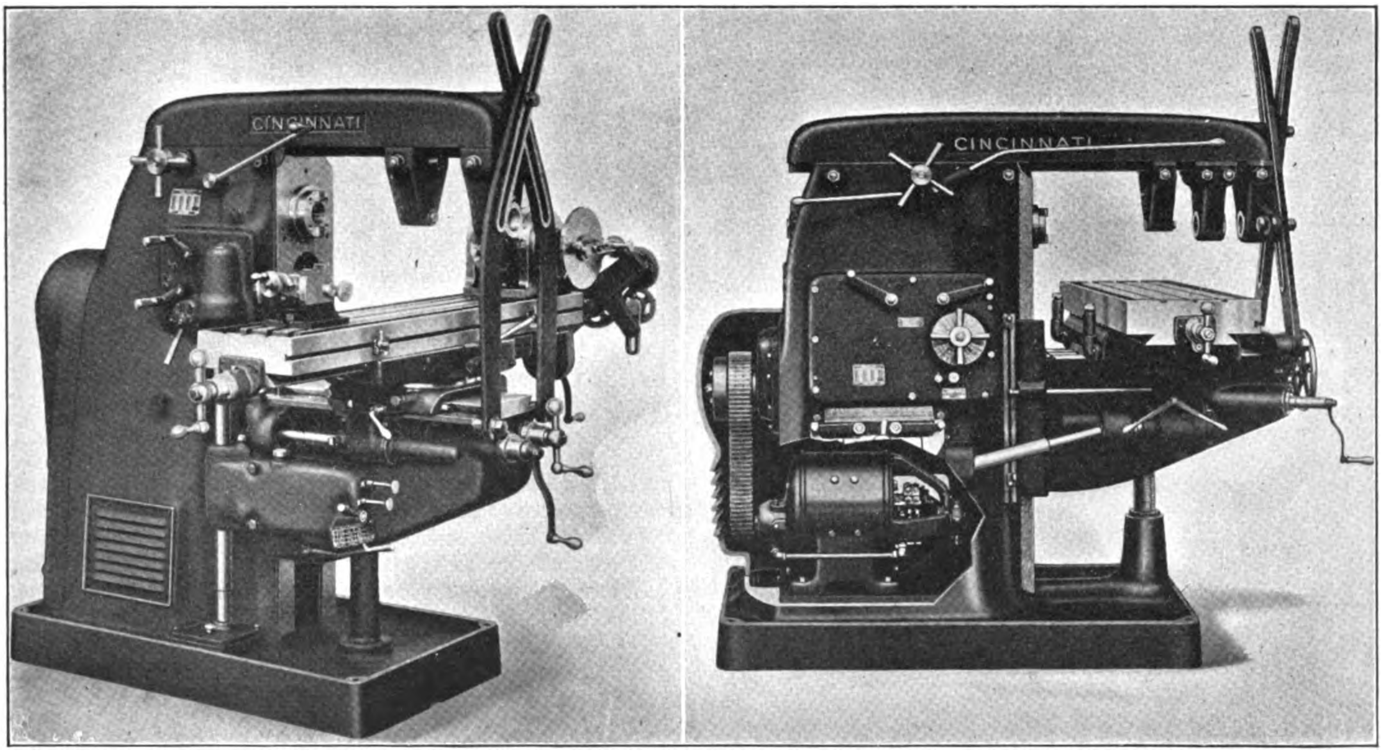
When starting a cut, the operator should take the pendent in one hand and the feed crank in the other. He can then feed in with confidence, as he can stop the machine instantly if the tool approaches a high spot on the work. Any lumps on the casting may be removed by a few short strokes, and considerable time is saved in starting the cut.

Another possible source of accident is failure of voltage. This occurs at times in every plant due to powerhouse trouble, blowing of fuses or opening of circuit breakers. As a result, the planer motor is left without a field and unless some means of stopping is provided, the planer will overtravel. Overtravel of a planer table is apt to cause serious damage, both to the work and to the machine, and is dangerous for the operator. Overtravel of planers having Niles-Bement-Pond controllers is prevented by the patented emergency brake winding and circuit breaker. If the voltage falls below a safe minimum, the breaker opens instantly and applies a powerful dynamic brake, stopping the planer at once. The special brake winding takes power from the armature when the breaker opens and is effective regardless of the reduction in line voltage. The circuit breaker prevents the planer from starting on return of the voltage, and also gives complete overload protection.

The crossrail elevating motor is also interlocked with the main driving motor, so that it can be run only when the planer is stopped. It may be controlled from either side of the bed or from the pendent switch, assuring the operator a good view of the work.

Milling machines adaptable for railroad shops

THE milling machines shown in the illustrations have recently been placed on the market by the Cincinnati Milling Machine Co., Cincinnati, Ohio. Both of these machines contain new features of design heretofore not a part of the older types of machines. The column is interchangeable for overhead belt or enclosed motor drive. The motor is bolted to a flat plate machined on both sides, which in turn is securely fastened to the box section base of the machine by heavy bolts. The drive from the motor to the shaft is by means



The left view shows the pyramid column M Type Universal milling machine—At the right is the No. 2 and No. 3 high power pyramid column milling machine with the column broken away showing the location of the motor

The most prominent change in design is the pyramid form column which tapers gradually in a straight line from the overarms to the rim of the base. The purpose of this design is to provide maximum strength and rigidity to the column, a proper foundation for heavy cutting and a space for an enclosed motor drive.

of a silent chain. Ample ventilation is secured through vents in the sides of the column and the rear cover of the motor compartment. Provision is made for easily and quickly oiling the motor and adjusting the brushes through the vent holes.

The speed mechanism of these machines are provided

with tapered roller bearings, which are new with these machines. Besides the two features already mentioned, the following are also common to both types of machines. Automatic oiling in the column; centralized oiling for the knee, saddle and table; power rapid traverse; sliding gear transmission; multiple disc clutch running in oil; double starting levers, and rectangular overarms.

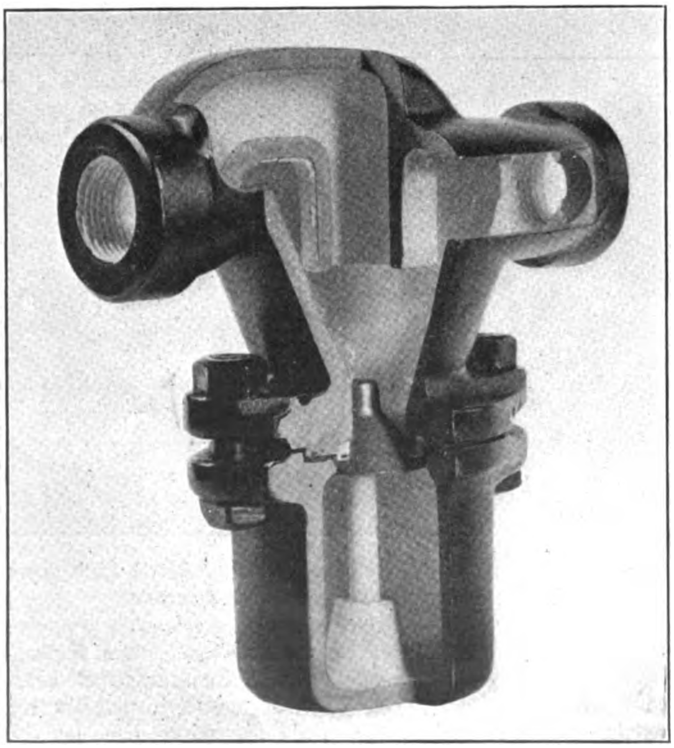
Careful consideration has been given in the arrangement of the levers so that the operator can control the machine from one position, thus eliminating any unnecessary movements about the machine. Double control levers have been provided so that the machines can be operated from either side.

The type M machine contains several refinements in design. A properly designed tapered gib connection to the column eliminates the necessity for clamping the knee, even when taking the heaviest cuts. A single piece vertical screw instead of the usual telescopic screw construction is employed. This arrangement lends itself in obtaining accurate and reliable dial readings. The saddle bearings for the table are as long as the full table travel. The wide knee bearing reduces the tipping tendency to a minimum.

There are certain fundamental differences between the M-type machine and the No. 2 and No. 3 machines. On the M-type machines the feed box is at the front of the knee, whereas on the No. 2 and No. 3 machines it is located at the side of the column. The power quick traverse is not supplied on the former type, whereas it is supplied on the latter.

Westinghouse centrifugal dirt collector

THE improved centrifugal dire collector recently developed by the Westinghouse Air Brake Company, Wilmerding, Pa., will contribute to economy and better maintenance of brake equipment. This



Centrifugal dirt collector containing a large dirt chamber and valve to prevent blow-back

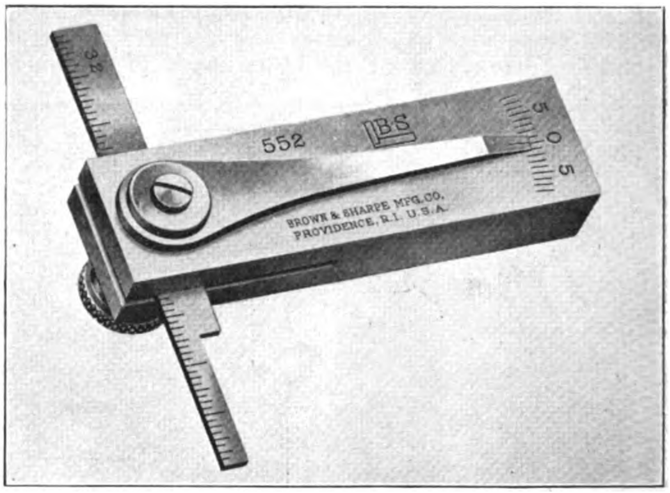
is due to the generous size of the chamber in which the dirt is deposited, its large capacity making it possible to accommodate all the dirt entering between cleaning periods. Moreover, cleaning is easily accomplished, it being necessary to remove but two bolts and drop the reservoir.

Another feature of the design is that obtained by the brass umbrella-shaped valve which floats on a stem in the lower chamber. Consequently, during charging of the equipment the swirling air currents impart a rocking motion to the valve which in turn deflects dirt particles into the chamber. The rapid reduction of the air pressure above the valve causes it to lift and seal on the seat, thereby isolating the dirt chamber so that no dirt can re-enter the brake system after once being collected. It is supplied both with and without drain cocks.

A diemaker's square

THE gage shown in the illustration is a handy tool for establishing clearances of drop forging dies and die castings. The pattern maker can also check drafts of patterns with it. This versatile gage is sold by the Brown & Sharpe Manufacturing Company, Providence, R. I.

It is easily set at any angle within its capacity by simply moving the pointer to the correct graduation mark



Brown & Sharpe diemaker's square

and tightening the knurled nut. The blade moves with the pointer. The graduations on the body read eight degrees on either side of the zero mark. Thus, the angle of clearance or draft setting is obtained by direct reading. A protractor is not required for setting this tool.

The blade is carefully graduated for 1 in. from either end—one side in 1/32 in., the other, in 1/64 in. The narrow end of the blade is 7/64 in. wide for small holes and the other end is 7/32 in. wide. The body is hardened and ground.

THE LAW OF NEW YORK requiring all locomotives to have side vestibule cabs, which has been before the courts for years, because of the refusal of the Public Service Commission to enforce it, has finally ben enullified by the Court of Appeals, which recently handed down a decision sustaining the commission in its ruling. The commission held that as the federal law covered the whole field of locomotive inspection, the state had no power to act. The firemen's brotherhood challenged the judgment of the commission and entered the suit to compel it to recognize the statute.

General News

The employees of the Paris (Ky.) shops of the Louisville & Nashville on July 31 completed a full year of work without a reportable injury to any employee.

The shops of the Delaware, Lackawanna & Western have been ordered to work only four days a week, the amount of car repair work having fallen off because of the strike in the anthracite mines. About 2,500 men are affected.

The Interstate Commerce Commission has denied a petition of the Chicago, Milwaukee & St. Paul for a suspension until further order of the second automatic train control order, entered January 14, 1924; but has granted another petition for an extension of time from July 1 to January 1, 1926, for the fulfilment by this road of the requirements of the first order (June 13, 1922). The commission has also postponed the effective date of the first order for the Chicago & North Western from July 1 to January 1, 1926.

Shop construction on the Chesapeake & Ohio

A contract has been awarded to Milo R. Hanke, Cincinnati, O., for the erection of a new boiler shop for the Chesapeake & Ohio at Huntington, W. Va. The building will be of steel and brick construction with a cement tile roof and a wood block floor, 140 ft. by 404 ft. It will have a boiler shop bay 90 ft. wide with a clear height of 40 ft. 6 in. and a machine bay 50 ft. wide with 37 ft. clear height. Two 15-ton electric traveling cranes will be installed in the machine bay and a 50-ton one in the boiler bay. The building will also have a number of 2-ton and 5-ton jib cranes. Modern machine tool equipment will be provided. The total cost of the project is estimated at $575,000.

Pennsylvania gives extensive automatic train control order

The Pennsylvania Railroad has given to the Union Switch & Signal Company a contract for automatic train control, the Union continuous induction system providing for the installation of the system on over 1,000 miles of road. Locomotives to the number of 1,000 will be equipped. This proposed work, complying with the Interstate Commerce Commission's general policy, will cost from six to seven millions of dollars.

Cost of fuel

The cost of fuel for road locomotives in freight and passenger train service (charged to operating expenses) for Class I steam roads for the first six months of 1925 was $163,120,525, according to the monthly report published by the Interstate Commerce Commission, as compared with $185,572,620 in the corresponding period of 1924. The average cost of coal per ton was $2.78, as compared with $3.18 last year, but the average cost of fuel oil increased from 2.73 cents a gallon to 3.17 cents. For the month of June the average cost of coal was $2.70 and the average cost of oil was 3.28 cents, making the total cost of coal and fuel oil for the month $24,376.103, as compared with $25,314,756 last June. For the six months' period the number of net tons of coal consumed was only 47,406,574, as compared with 49,721,957 last year.

Locomotives inspected

During August 6,604 locomotives were inspected by the Bureau of Locomotive Inspection of the Interstate Commerce Commission, according to its monthly report to the President on the condition of railroad equipment. Of these 2,689, or 40 per cent were found defective and 275 were ordered out of service. During the same month 121,328 freight cars were inspected, of which 3.3 per cent were found defective, and 2,421 passenger cars, of which 27 were found defective. During the month 17 cases, involving 32 violations of the safety appliance acts, were transmitted to various United States attorneys for prosecution.

N. Y. C. runs passenger engine without change between Harmon, N. Y., and Chicago

On Sunday, September 13, New York Central engine No. 3334 completed its first round trip from Harmon, N. Y., to Chicago and return without change en route. The locomotive left Harmon, the terminal of the electrified division out of New York City, Thursday afternoon, September 10, at 6:30 p. m., eastern standard time, on the Lake Shore Limited, arriving at Chicago September 11 at 4:00 p. m., central standard time, after a continuous operation of 946 miles in 22½ hrs. After a layover of approximately 24 hrs., this locomotive started the return trip on the Lake Shore Limited at 5:30 p. m. Saturday, September 12, completing the trip at Harmon the next day at 4:22 p. m. This constitutes a record for the New York Central which, however, already has increased the length of the locomotive runs on its through passenger trains so that the present practice is to change engines at Buffalo only, where formerly seven locomotives were required to complete the run between Harmon and Chicago.

New freight cars placed in service

A total of 83,291 freight cars was placed in service during the first six months of 1925 by Class I railroads, according to a statement issued by the Car Service Division of the A. R. A. This was an increase of 12,417 cars as compared with the number installed in the corresponding period of last year and an increase of 4,051 cars as compared with 1923. The total included 43,627 box cars, 29,504 coal cars and 3,382 refrigerator cars. There was, however, a substantial reduction in the number of new freight cars on order on July 1, to 28,197, as compared with 60,315 last year and 96,855 in 1923.

Class I railroads during the first half of 1925 also placed in service 927 steam locomotives, compared with 1,071 during the same period last year and 1,998 during the same period in 1923. The same roads on July 1, 1925, had 279 locomotives on order compared with 360 on the same day last year and 1,902 two years ago.

The figures as to cars and locomotives include new, rebuilt and leased equipment.

The average capacity of the freight cars owned by the Class I railroads on July 1 this year was 44.56 tons, as compared with 43.88 tons on the same date last year, or an increase of 1.5 per cent. The average tractive power per locomotive on July 1 this year was 40,215 pounds, as compared with 39,571 pounds on the same date last year, or an increase of 1.6 per cent.

Anniversary and celebration of Pitcairn car shop

The tenth thousand car was recently turned out of the steel car shop of the Pennsylvania at Pitcairn, Pa., and this event was celebrated by an old-fashioned anniversary and celebration, consisting of athletic contests, musical entertainments, dancing and band concerts. The Pitcairn car shop, established in 1890, consisted of a roundhouse for repairing freight cars, a small brick office building and four repair tracks. The present roundhouse in which repairs are made to freight and passenger cars and locomotive tenders, contains 42 repair tracks. The steel freight car repair shop, erected in 1923 at a cost of approximately $1,000,000, is equipped with all modern and labor-saving devices. The main building of this shop is 100 ft. wide and 620 ft. long, and the rivet cutting building, 35 ft. wide and 200 ft. long. Approximately 800 men are employed in the steel car shop and a car is rebuilt and turned out every 24 min. Passenger cars are given heavy running repairs, and there is also a progressive system for class repairs to 22 passenger cars per month, this being the only class repair shop in the Central region. About 4,000 freight cars are repaired on various repair tracks per month. Repairs also are made to locomotive and car air brake parts for all points on the Western Pennsylvania division. There is a machine shop, forge

shop, paint shop, cabinet shop, upholstering shop, tin shop, blacksmith shop and a large stores department which furnishes material for the entire shop.

Progress in train control installation

The work of installing automatic train control devices in accordance with the orders of the Interstate Commerce Commission, which will require the expenditure of approximately $26,000,000 by the 45 roads named in Order No. 1, is progressing rapidly, according to a statement issued by W. J. Harahan, chairman of the Committee on Automatic Train Control of the American Railway Association.

Up to August 1 this year, out of 7,745 miles of track of the 45 carriers designated for installation of train control devices, installation had either been completed or was under way on divisions totaling 5,044 miles, or 65 per cent of the total mileage covered by the order. On January 1, last, installation had been completed or was under way only on 3,592 miles, or 42 per cent.

All of the 45 roads have selected a train control device for installation. Three roads have selected the ramp type, 23 the intermittent induction type, 13 the continuous induction type, and 6 the plain automatic stop using continuous control.

Thirteen roads have completed permanent installation, while 16 roads have permanent installation now under construction. Preliminary installations have been completed by 13 roads, while 3 others have preliminary installations now under construction.

The original order of the commission named 49 roads, but the Chicago, St. Paul, Minneapolis & Omaha; the Buffalo, Rochester & Pittsburgh; the Western Maryland, and the Chicago & Erie were later exempted. The commission on January 14, 1924, in its order, No. 2, also ordered 47 of the roads listed originally to install train control devices on a second division, but later exempted five of those roads. The commission in its Order 2 also ordered 45 additional roads to equip one division prior to February 1, 1926. Later, at the request of the carriers, the commission also suspended the second order so far as the 45 additional roads were concerned.

The permanent installations completed or in service, according to reports of the roads to the Interstate Commerce Commission, are as follows:

Road	Location	Maker	Mileage
Atchison, Topeka & Santa Fe	Chillicothe, Ill., to Shopton, Ia.	Union	209
Chesapeake & Ohio	Gordonsville to Staunton, Va.	American	61
Chicago & Eastern Illinois	Chicago to Danville, Ill.	Miller	210.8
Chicago, Rock Island & Pacific	Blue Island to Rock Island, Ill.	Regan	330
Galveston, Harrisburg & San Antonio	Rosenberg to Gidden, Tex.	National	50.6
Missouri Pacific	Leeds, Mo., to Osawatomie, Kan.	National	49.9
New York, New Haven & Hartford	Air Line Jct., to Springfield, Mass.	General and Union	124
Norfolk & Western	Hagerstown to Shenandoah, Va.	Union	105.8
Oregon-Washington R. R. & Navigation Co.	Portland to The Dalles, Ore.	Union	86.5
Reading	Camden to Atlantic City, N. J.	Union	108.2
Southern Pacific	Oakland to Tracy, Calif.	National	98.8
St. Louis-San Francisco	Nichols to Monett, Mo.	National	44.4
Union Pacific	Sidney, Neb., to Cheyenne, Wyo.	Union	204

Permanent installations are under construction on the Atchison, Topeka & Santa Fe (second Order); Atlantic Coast Line; Baltimore & Ohio; Central of New Jersey; Chicago, Burlington & Quincy; Chicago & Northwestern; Chicago, Milwaukee & St. Paul; Cincinnati, New Orleans & Texas Pacific; Delaware, Lackawanna & Western; Great Northern; Illinois Central; Louisville & Nashville; Northern Pacific; Pennsylvania; Pere Marquette, and Southern.

Preliminary installations are in operation or have been completed by the Boston & Albany; Boston & Maine; Chicago & Alton; Chicago, Indianapolis & Louisville; Delaware & Hudson; Kansas City Southern; Lehigh Valley; Michigan Central; New York Central; New York, Chicago & St. Louis; Pennsylvania; Pittsburgh & Lake Erie, and Richmond, Fredericksburg & Potomac.

Preliminary installations are under construction on the Cleveland, Cincinnati, Chicago & St. Louis; Erie, and Long Island.

The three roads that have selected the ramp type are the Chesapeake & Ohio (American); Chicago & Eastern Illinois (Miller), and Chicago, Rock Island & Pacific (Regan).

The twenty-three that have selected the intermittent induction type are the Atlantic Coast Line; Boston & Albany; Cincinnati, New Orleans & Texas Pacific; Cleveland, Cincinnati, Chicago & St. Louis; Delaware & Hudson; Erie; Kansas City Southern; Lehigh Valley; Michigan Central; New York Central; Pere Marquette, and Southern, of the type of the General Railway Signal Company; the Chicago & Alton; Galveston, Harrisburg & San Antonio; Missouri Pacific; St. Louis-San Francisco, and Southern Pacific, of the type of the National Safety Appliance Company; the Chicago, Burlington & Quincy; Chicago, Indianapolis & Louisville; Great Northern, and Northern Pacific, of the type of the Sprague Safety Control and Signal Corporation; and the New York, Chicago & St. Louis, and the Pittsburgh & Lake Erie, of the type of the Union Switch & Signal Company.

The thirteen that have selected the continuous induction type are the Chicago & Northwestern and Baltimore & Ohio (General Railway Signal Company), and the Boston & Maine; Delaware, Lackawanna & Western; Long Island; Louisville & Nashville; Oregon-Washington Railroad & Navigation Company; Richmond, Fredericksburg & Potomac; Union Pacific; Atchison, Topeka & Santa Fe; Norfolk, Western, and Reading (Union Switch & Signal Company).

The six that have selected plain automatic stop are the Chicago, Milwaukee & St. Paul; Illinois Central; New York, New Haven & Hartford; Pennsylvania; Pittsburgh, Cincinnati, Chicago & St. Louis; and West Jersey & Seashore (Union Switch & Signal Company).

Meetings and Conventions

Steel Treaters convention at Cleveland

The seventh annual convention and exposition of the American Society for Steel Treating was held at Cleveland, Ohio, September 14 to 18 inclusive, and in attendance and in size of exhibition undoubtedly surpassed any convention yet held by the Society. While official attendance figures are not yet available it is understood that the total registration, including guests, was in the neigh-

Freight cars installed and retired

Month—1925	Installed during month	Aggregate capacity tons	Retired during month	Aggregate capacity tons	Owned at end of month	Aggregate capacity tons
January	11,768	551,263	7,867	326,812	2,341,109	103,812,974

May	65,651	1,276,826	1,342,477
June	71,789	1,296,558	1,368,347
July	70,087	1,330,595	1,401,682

borhood of 3,500. There were 180 exhibitors of machine tools and steel treating and testing equipment, and a great number of the exhibits were in actual operation. The technical sessions were well attended and the appreciation of the many excellent papers presented was indicated by the discussion which followed. Among the subjects covered were tool steels, carburizing, welding and tool tempering and hardness testing.

The following officers were nominated: President, R. M. Bird, Philadelphia; vice-president, J. F. Harper, Milwaukee, Wis.; directors, R. G. Guthrie, Chicago, and H. Bornstein, Moline, Ill. Chicago was selected for the 1926 convention.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs.

AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

AMERICAN RAILWAY ASSOCIATION, DIVISION V.—MECHANICAL—V. R. Hawthorne, 431 South Dearborn St., Chicago.

DIVISION V.—EQUIPMENT PAINTING SECTION.—V. R. Hawthorne, Chicago.

DIVISION VI.—PURCHASES AND STORES.—W. J. Farrell, 30 Vesey St., New York.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—G. G. Macina, 11402 Calumet Ave., Chicago.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Regional meeting October 5-7, at Altoona, Pa. Technical program on transportation problems. Railroad Division. A. F. Steubing, Bradford Corp., 25 West Forty-third St., New York.

AMERICAN SOCIETY FOR STEEL TREATING.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio.

AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago, Ill. Annual meeting, October 27 to 30, inclusive, Hotel Sherman, Chicago.

CANADIAN RAILWAY CLUB.—C. R. Crook, 129 Charron St., Montreal, Que. Regular meetings second Tuesday in each month, except June, July and August, at Windsor Hotel, Montreal, Que.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 N. Pine Ave., Chicago, Ill. Meeting second Monday in month, except June, July and August, Great Northern Hotel, Chicago, Ill.

CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—R. E. Giger, 721 North 23rd St., E. St. Louis, Ill. Meetings, first Tuesday in month, except June, July and August, at the American Hotel Annex, St. Louis.

CAR FOREMEN'S CLUB OF LOS ANGELES.—J. W. Krause, 514 East Eighth St., Los Angeles, Cal. Meeting second Friday of each month in the Pacific Electric Club building, Los Angeles, Cal.

CENTRAL RAILWAY CLUB.—H. D. Vought, 26 Cortlandt St., New York, N. Y. Regular meetings, second Thursday each month, Hotel Statler, Buffalo, N. Y. Next meeting October 15. A paper on Supplies—Their Distribution and Cost will be presented. Moving pictures of N. Y. C. scrap yard at Cleveland.

CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—A. S. Sternberg, Belt Railway, Clearing Station, Chicago.

CINCINNATI RAILWAY CLUB.—W. C. Coder, Union Central Building, Cincinnati, Ohio. Meetings, second Tuesday, February, May, September and November.

CLEVELAND STEAM RAILWAY CLUB.—F. D. Frericks, 14416 Adler Ave., Cleveland, Ohio. Meeting first Monday each month except July, August and September, at Hotel Cleveland, Public Square, Cleveland.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—W. J. Mayer, Michigan Central, 2347 Clark Ave., Detroit, Mich.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. B. Hutchinson, 1809 Capitol Ave., Omaha, Neb. Next meeting May 11-14, 1926, Hotel Sherman, Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabash Ave., Winona, Minn.

MASTER BOILER MAKERS' ASSOCIATION.—Harry D. Vought, 26 Cortlandt St., New York, N. Y.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meeting second Tuesday in month, except June, July, August and September. Copley-Plaza Hotel, Boston, Mass. Next meeting October 13. A paper will be read by J. H. Hustis, president, Boston & Maine.

NEW YORK RAILROAD CLUB.—H. D. Vought, 26 Cortlandt St., New York. Meeting third Friday each month, except June, July and August, at 29 West Thirty-ninth St., New York. Next meeting October 16. Younger men's night.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgreb, 625 Brisbane Building, Buffalo, N. Y. Regular meetings, January, March, May, September and October.

PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Regular meetings, second Thursday of each month in San Francisco and Oakland, Cal., alternately.

RAILWAY CLUB OF GREENVILLE.—F. D. Castor, clerk, maintenance of way department, Bessemer & Lake Erie, Greenville, Pa. Meeting last Friday of each month, except June, July and August.

RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Regular meeting fourth Thursday in month, except June, July and August. Fort Pitt Hotel, Pittsburgh, Pa.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, second Friday in each month, except June, July and August.

SOUTHEASTERN CARMEN'S INTERCHANGE ASSOCIATION.—J. E. Rubley, Southern Railway shops, Atlanta, Ga.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, 1177 East Ninety-eighth St., Cleveland, Ohio.

WESTERN RAILWAY CLUB.—Bruce V. Crandall, 189 West Madison St., Chicago. Regular meetings, third Monday in each month, except June, July and August.

Supply Trade Notes

The National Lock Washer Company has moved its Chicago offices from 1535 Lytton building to 1103 Straus building.

G. P. Donelson, formerly president of the Continental Bolt & Iron Works, Chicago, died in California on September 3.

The General American Tank Car Corporation has acquired the plant of the Lone Star Tank Company of Fort Worth, Tex., and Wichita Falls.

John H. Ohlsson, assistant general manager of sales of the J. G. Brill Company, died suddenly on September 3, at his home in Philadelphia, Pa.

The Independent Pneumatic Tool Company, Chicago, has opened a branch office at 288 East Water street, Milwaukee, Wis., in charge of G. H. DuSell.

G. H. Woodroffe has been appointed metallurgical engineer, a newly created position, of the Reading Iron Company's boiler tube department at Reading, Pa.

The Marlin-Rockwell Corporation, New York, manufacturers of ball bearings, has purchased the plant of the Strom Ball Bearing Manufacturing Company, Chicago.

John J. Hannahan, assistant to the president of the Locomotive Stoker Company, Pittsburgh, Pa., died at his home in Merriam Park, Minn., on September 4, after a brief illness.

Stephen F. Sullivan, vice-president of the Ewald Iron Company, with headquarters in Chicago, died in Benton Harbor, Mich., on September 6, after a short illness of heart trouble.

E. J. Bartlett, general manager of the Baker R & L Company, Cleveland, Ohio, has been elected president, to succeed F. W. Treadway, who has been made chairman of the board of directors.

L. M. Zimmer has been appointed general sales manager of the Linde Air Products Company, manufacturers of oxygen, and of the welding gas division of the Prest-O-Lite Company, Inc., manufacturers of dissolved acetylene, succeeding L. M. Moyer, resigned.

Victor W. Ellet has been appointed sales manager of the Hunt-Spiller Manufacturing Corporation, with headquarters at Boston, Mass., in succession to John G. Platt, whose jurisdiction as vice-president has been extended to cover operation as well as sales.

Milburn Moore, eastern engineering editor of the Railway Age and Railway Engineering and Maintenance, has resigned to become associated with the Verona Tool Works, Pittsburgh, Pa., as district sales manager, with headquarters at 50 Church street, New York.

The Independent Pneumatic Tool Company, manufacturers of Thor pneumatic tools and electric tools, has opened a branch office at Milwaukee, Wis., in charge of G. H. Du Sell, who has represented the company in this territory for a number of years. The new office will be located at 288 East Water street.

The Hulson Grate Company, Inc., Keokuk, Iowa, which bought the Pechstein Iron Works, in Keokuk, last April, has recently placed the plant in operation. The machine and boiler shops have been discontinued and the foundry has been re-equipped and modern machinery installed for the manufacture of Hulson grates.

Joseph V. Miller, western sales representative of the Prime Manufacturing Company, Milwaukee, Wis., has resigned to go to the Chicago, Milwaukee & St. Paul as assistant general storekeeper. C. Arthur Dunn, eastern sales representative of the Prime Manufacturing Company, with headquarters at Philadelphia, has been promoted to sales manager, railway division, with headquarters at Milwaukee.

The Locomotive Terminal Improvement Company, Chicago, has taken over the manufacturing department of the National Boiler Washing Company, Chicago. This includes the manufacture of leadized pipes, leadized boiler tubes for both locomotive and stationary use, post and pillar cranes, and other locomotive terminal facilities. Officers of the Locomotive Terminal Improvement Company are: President, Spencer Otis, president of the National Boiler

Washing Company; secretary and treasurer, John S. Maurer, vice-president and treasurer of the National Boiler Washing Company; chief engineer, F. S. Wichman, chief engineer of the National Boiler Washing Company; and sales engineer, W. J. Wignall, of the engineering and purchasing department of the National Boiler Washing Company.

M. A. Weidmayer, formerly branch manager of the Black & Decker Manufacturing Company, is now in charge of the Philadelphia office of the United States Electrical Tool Company, and C. H. Scaffe, formerly connected with the Black & Decker Manufacturing Company at St. Louis, is now a special representative of the United States Electrical Tool Company, operating from the general office at Cincinnati, Ohio.

The C. H. Hollup Corporation, formerly the International Welding Engineering Corporation, Chicago, manufacturer of welding wire and supplies, has purchased 15,000 sq. ft. of land on South Turner avenue and West 48th Place, upon which it will construct a factory building. The building will have approximately 12,000 sq. ft. of floor space and will be of brick and mill construction with faced brick, terra cotta trimmed on the north and east ends.

L. G. Plant, assistant to the president of the National Boiler Washing Company, Chicago, has resigned to engage in selling and financing locomotive terminal utilities, with offices in the Railway Exchange building, Chicago. He will represent the T. W. Snow Construction Company as general railway sales agent for this company's unit system locomotive coaling station and the Locomotive Terminal Improvement Company as general sales agent for the direct steaming system.

The Dearborn Chemical Company contemplates the construction of a warehouse in Los Angeles, Cal., while the plant under construction in Chicago will be ready for occupancy on October 17. This company has appointed V. Cattoretti & Co., La Paz, Bolivia, its agent for oils and greases in Bolivia. It has also appointed Graham, Rowe & Co., Lima, Peru, its agent for oils and greases. This company has been agent for the Dearborn Chemical Company for its water treatment service and chemicals.

E. H. Wood, former master car builder of the Michigan Central, has joined the sales force of the Grip Nut Company as district sales manager, with headquarters in Chicago. Mr. Wood entered the service of the Canadian Pacific as a car repairer in 1899, and subsequently was successively car inspector, foreman, general foreman and general car foreman until September, 1915, when he resigned. The following month he went to the Michigan Central as inspector at Kensington. He was appointed general car foreman in November of the same year, and assistant master car builder in May, 1919. Mr. Wood was appointed master car builder in May, 1920, and later became passenger car foreman at Chicago, remaining in that service until January of this year.

E. H. Wood

John T. Llewellyn, vice-president of the Chicago Malleable Castings Company and president of the Allied Steel Castings Company, Chicago, has been elected president of the Chicago Malleable Castings Company, to succeed Silas J. Llewellyn, deceased. James S. Llewellyn, secretary of the Chicago Malleable Castings Company, and secretary and works manager of the Allied Steel Castings Company, has been elected vice-president, general manager and secretary of the Chicago Malleable Castings Company, and vice-president, general manager and secretary of the Allied Steel Castings Company. Paul Llewellyn, treasurer of the Chicago Malleable Castings Company and vice-president of the Interstate Iron & Steel Company, has been elected vice-president and treasurer of the Chicago Malleable Castings Company.

John T. Llewellyn was born in Briton Ferry, Wales, and came to America in 1864. He was educated in the public schools of Cleveland, Ohio, and Chicago, and in 1880 he entered the employ of the Illinois Steel Company as a telephone operator. In 1896 he organized the Valve Setting Company, Racine, Wis., and in 1898 he organized the Chicago Malleable Castings Company, of which he has since been vice-president and general manager. James S. Llewellyn was born in 1887 in Milwaukee and was graduated from the University of Michigan in 1908. After leaving school he entered the employ of the Chicago Malleable Castings Company and worked in the shops, occupying several positions until 1915, when he was appointed secretary, which position he has held until his recent promotion. Paul Llewellyn was born in 1886 and was educated at Yale University. In 1908 he entered the employ of the Interstate Iron & Steel Company, since which he has been manager of the East Chicago works, sales manager, vice-president of the latter company and treasurer of the Chicago Malleable Castings Company.

William H. Heulings, Jr., vice-president and general manager of sales of the J. G. Brill Company, Philadelphia, died on September 14 in the Jefferson Hospital, that city, after a brief illness. Mr. Heulings has been identified with the Brill Company since boyhood, starting in February, 1885, as a stenographer. He was transferred to the sales branch of the business at the age of twenty and became assistant secretary of the company in 1901, and in 1903 assumed, in addition, the duties of general manager of sales. In June, 1914, he was elected vice-president and held this joint responsibility at the time of his death. Mr. Heulings was born on November 17, 1869, in Philadelphia, and received his education in the public schools of that city. He was also vice-president and a director of the American Car Company, St. Louis, Mo., and a director of both the G. C. Kuhlman Car Company, Cleveland, and the Wason Manufacturing Company, Springfield, Mass., subsidiaries of the J. G. Brill Co.

W. H. Heulings, Jr.

Control of the Hall-Scott Engine Company, Oakland, Calif., manufacturers of motors for the Fageol Motors Company, has been acquired by the American Car & Foundry Company. The J. G. Brill Company is associated with the American Car & Foundry Company in this purchase. Reports are current that control of the Brill Company is about to pass to new interests. One rumor is to the effect that there is in contemplation the formation of a new company to be controlled by the American Car & Foundry Company or interests associated with the latter. The new company, it is said, will take over control of the Brill Company, the Hall-Scott Engine Company and the Fageol Motors Company, of Ohio. The American Car & Foundry Company has issued the following statement denying these rumors:

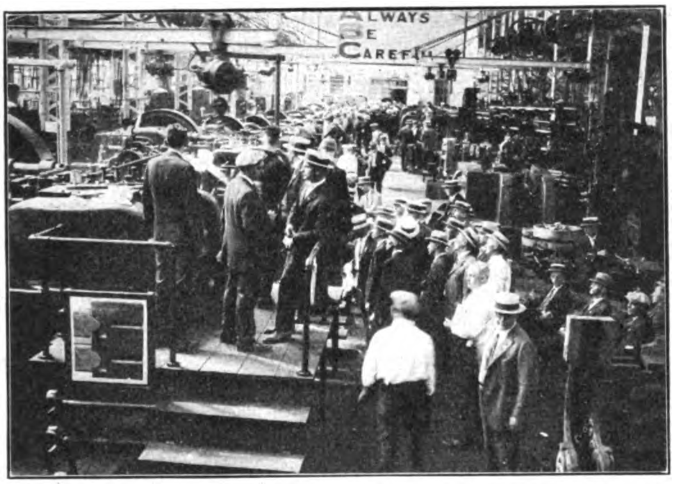
> Following the announcement that American Car & Foundry Company had purchased a controlling interest in the Hall-Scott Motor Car Company of Berkeley, Cal., it was persistently rumored that it had also acquired certain companies to whom Hall-Scott Company had been supplying gas engines for use in motor trucks, buses, etc. Fageol Motor Company of California, Fageol Motor Company of Ohio and the J. G. Brill Company were mentioned as having been thus acquired. American Car & Foundry Company denies that it has purchased control of these or any other customers of the Hall-Scott Company, and states that the rumors are unfounded.

National Machinery Company exhibits forging machinery

The National Machinery Company held its second annual exhibition and demonstration of forging machinery at its plant, Tiffin, Ohio, August 21 to 26, 1925, inclusive. The first day of the exhibition was set aside as Master Blacksmiths' day, and practically

all those in attendance at the convention of the International Railroad Master Blacksmiths' Association at Cleveland, Ohio, attended. Special arrangements were made for the transportation of the members and other guests between Cleveland and Tiffin.

This exhibition was the second of its kind to be conducted by the National Machinery Company, the first being held fifteen years ago. The entire plant was used for the exhibition of the various machine tools, production work practically ceasing while the exposition was in progress. A total of 62 machines, of which 35 were



Visitors watching a demonstration—62 machines were on exhibition, 35 of which were in operation

in operation, and 10 furnaces were on exhibit. Forging machines ranging from 1 in. to 5 in. capacity, each equipped with the necessary dies and furnaces, were in actual production on forging jobs. A number of continuous automatic feed bolt and rivet headers were also in operation, in which many improvements designed to expedite production have been incorporated. In addition there were on exhibit, bolt heading machines fed by a new type of automatic electric header, semi-automatic bolt heading machines, semi-automatic and automatic nut tappers, automatic thread bolt trimmers, rolled thread bolt machines and a battery of bolt cutters. These

Interior view of the National Machinery Company's plant, Tiffin, Ohio, during the exposition

bolt machines constituted a complete bolt producing plant. Some of the more interesting forging jobs demonstrated to the master blacksmiths the possibilities of the forging machine in railway blacksmith shop work for the production of locomotive cylinder cocks, brake lever fulcrums, side rod nuts, freight car floor bolts, brake hangers, locomotive ash pan levers, handholes or grab irons, and brake chain clevices.

The exhibition also demonstrated the various stages of manufacture of the machines produced by the National Machinery Company and how the various parts functioned when in actual operation.

Trade Publications

Screw, nut and stud drivers.—A 12-page brochure, descriptive of portable electric screw, nut and stud drivers, has been issued by the United States Electrical Tool Company, Cincinnati, Ohio. Charts showing capacities of different models and pilot hole sizes and specifications are also included.

Trucks and tractors.—A 40-page catalogue descriptive of the mechanical features of the various types of Crescent trucks and tractors and showing the purpose for which each type is particularly adapted, has been issued by the Crescent Truck Company, Lebanon, Pa. Specifications and line drawings are also included.

Regulators.—The Alexander Milburn Company, Baltimore, Md., has issued an eight-page brochure descriptive of its standard regulators for oxygen, acetylene and other gases. The rear opening of the Milburn regulator is only 1⅛ in. diameter, which enables the cap to be unscrewed and the seat and nozzle to be immediately reached without undoing any other part.

Vertical turret lathe.—A four-page bulletin showing front and back cylinder head operations on vertical turret lathes having diameters 30½ in., 32 in., 34½ in. and 36 in., respectively, has been issued by the Bullard Machine Tool Company, Bridgeport, Conn. The side head and turret, which provides additional tooling capacity, ample support for heavy cuts and simultaneous cutting facilities, is also described.

"Net profits from small lots."—This is the title of a 16-page booklet issued by the Warner & Swasey Company, Cleveland, Ohio, which shows the way to net profits from small lot production by the use of universal turret lathes with standard tool equipment, making five to fifteen pieces of one kind at a time, thus cutting the time in half as compared to engine lathe methods. Illustrations show comparative facts about keeping the machine busy, set-up time, production and the net profit from the investment.

Pressure regulating devices.—General catalogue No. 62, descriptive of its pressure regulating devices, has been issued by the Mason Regulator Company, Boston, Mass. The catalogue, which contains 178 illustrated pages, is divided into five sections, Section I being devoted to pressure reducing valves; Section II, to automatic regulating devices for pumps and pressure regulators; Section III, to boiler pressure regulators, damper regulators and fan engine regulators; Section IV, to balanced valves, companion flanges, strainers and pilot valves, and Section V, to tables for obtaining sizes of pressure reducing valves, general information for engineers and contractors, and telegraphic code.

Feedwater heaters.—Instructions for the operation and maintenance of the Elesco locomotive feedwater heater are contained in a 74-page handbook recently issued by the Superheater Company, New York. After a brief description of the principle used in its design, the Elesco heater and its parts are described. The succeeding chapters deal with the operation, maintenance, inspection and test of the equipment, how it is cleaned, heater and pump repairs, and questions and answers regarding operation. Charts show in colors the various passages of live and exhaust steam, hot and cold water through a locomotive equipped with the Elesco heater and the passages of steam and water through various parts of the heater itself.

Electrical supplies.—The Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., is distributing its new 1925-27 catalogue of electrical supplies. The publication contains 1,200 pages and is profusely illustrated with 4,500 engravings. All new apparatus designed and manufactured in the past two years, as well as all the previous established types are listed. A very complete subject index in the front of the book is printed on blue paper so that it can be quickly located, and a style number index for checking invoices is located in the back of the book. A classified index under such classifications as central stations, electric railways, industrial plants, mines, etc., gives a complete list of apparatus applicable to each of these groups of industries, and the thumb index enables the user to locate any section of the catalogue with the least inconvenience.

Personal Mention

General

F. A. Starr has been appointed supervisor of reclamation of the Chesapeake & Ohio, with headquarters at Richmond, Va.

P. C. Morales has been appointed superintendent of machinery and motive power of the National Railways of Mexico, succeeding S. A. Alzati, resigned.

J. P. Roquemore, superintendent of motive power of the International-Great Northern at Palestine, Tex., has been promoted from mechanical assistant to executive vice-president, with headquarters at Houston, Tex., a newly created position.

S. T. Armstrong, master mechanic of the San Antonio division of the International-Great Northern at San Antonio, Tex., has been promoted to superintendent of motive power, with headquarters at Palestine, Tex., in place of J. P. Roquemore.

Master Mechanics and Road Foremen

O. C. Branch has been appointed road foreman of engines of the North Carolina division of the Seaboard Air Line, with headquarters at Hamlet, N. C.

George B. Riddle has been appointed assistant road foreman of engines of the North Carolina division of the Seaboard Air Line, with headquarters at Hamlet, N. C.

F. R. Butts has been appointed acting master mechanic of the Brookfield division of the Chicago, Burlington & Quincy, with headquarters at Brookfield, Mo., to succeed H. H. Urbach, who has been assigned to other duties.

Ammon Hambleton, whose appointment as master mechanic of the El Paso-Amarillo division of the Chicago, Rock Island & Pacific at Dalhart, Tex., was announced in the August issue of the *Railway Mechanical Engineer*, was born on November 4, 1883, at Aroca, Kans. He graduated from the Atchison, Kans., high school, and in January, 1900, entered the employ of the C. R. I. & P. at Horton, Kans., as a machinist apprentice. In July, 1902, he was transferred to the new Chickasha, Okla., shops, where he completed his apprenticeship in January, 1904. He then served as a machinist until November of the same year, when he was promoted to machine shop foreman. From October, 1906, to January, 1907, he was a machinist at Shawnee, Okla.; from January, 1907, to July, 1910, machine foreman, and from July, 1910, to April, 1914, roundhouse foreman, being transferred on the latter date to Chickasha, as general locomotive foreman. He was transferred to Shawnee as general locomotive foreman in April, 1917, and in April, 1920, appointed master mechanic of the Louisiana division, with headquarters at El Dorado, Ark. In June, 1921, the Louisiana division was consolidated with the Arkansas division under the jurisdiction of the Arkansas division staff, and Mr. Hambleton was transferred back to Shawnee as general foreman, locomotive department, in which position he remained until his appointment as master mechanic of the El Paso-Amarillo division.

A. Hambleton

Car Department

W. P. Pettus, car foreman of the Chicago & Eastern Illinois, at Terre Haute, Ind., has been appointed car foreman of the Gulf Coast Lines, with headquarters at Kingsville, Tex.

G. T. Patton has been appointed car foreman in charge of freight cars of the Baltimore & Ohio, with headquarters at Mt. Clare, Baltimore, Md., succeeding J. F. Ford, resigned.

Shop and Enginehouse

W. K. Gonnerman has been promoted to superintendent of shops of the entire Akron division of the Baltimore & Ohio.

A. E. Spurr has been promoted to assistant enginehouse foreman of the Northern Pacific, with headquarters at St. Paul, Minn.

E. J. Cole, superintendent of shops of the Union Pacific at Cheyenne, Wyo., has been transferred to Omaha, Neb., succeeding J. W. Highleyman.

J. W. Highleyman, acting superintendent of shops of the Union Pacific, has resumed his duties as assistant superintendent of motive power and machinery.

B. F. Hoard, assistant enginehouse foreman of the Northern Pacific at St. Paul, Minn., has been promoted to enginehouse foreman, with headquarters at Jamestown, N. D.

W. C. Rogers has been appointed supervisor of passenger locomotive operations on the South Carolina division of the Seaboard Air Line, with headquarters at Savannah, Ga.

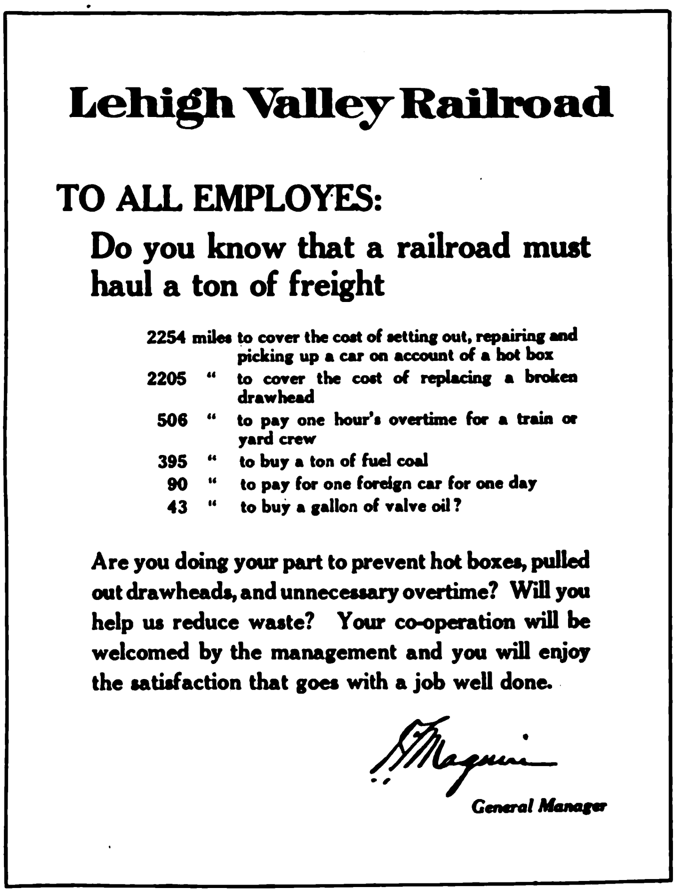
B. Koontz has been appointed supervisor of passenger locomotive operations on the Virginia and North Carolina divisions of the Seaboard Air Line, with headquarters at Raleigh, N. C.

Purchases and Stores

C. L. Tiller has been appointed division storekeeper of the Southern, with headquarters at South Richmond, Va., succeeding W. N. Pollard, deceased.

Obituary

J. H. Daley, mechanical superintendent of the New York, New Haven & Hartford, died in a hospital at Auburn, N. Y., on August 28.



Poster used on the Lehigh Valley in a campaign to prevent hot boxes

Railway Mechanical Engineer

Vol. 99 November, 1925 No. 11

The master workman uses great care in selecting his tools and keeping them in first-class condition. The officer or foreman is judged by the results he gets from his organization or the particular part of the organization over which he has control. He must constantly study to improve his ability and to exert a higher type of leadership. He needs good tools just as does the mechanic, but they are naturally of a very different sort. Among his tools are a knowledge of the right principles of dealing with the human element, of the best methods and practices of doing work over which he has supervision, and the best types of facilities and equipment for use in his department. Progress is continually being made in all these matters. It is no small task to keep up with this progress, even for a foreman who has a comparatively limited part of the organization under his direction. It requires constant study and a knowledge of what is being done by others in the same class of work. The *Railway Mechanical Engineer* is specially designed to meet these needs of railway mechanical officers and foremen.

Using the Railway Mechanical Engineer

It is not easy for the average man to read or study books or technical publications, but nevertheless it is vital for him to do so if he expects to advance or even to hold his own if he is in a supervisory position. The men at the head of an organization or a department have a grave responsibility in seeing that those associated with them are properly encouraged and inspired to develop and make better use of their peculiar talents. One of the contributors to this number, whose letter is included in the article on the "Bill Brown-Top Sergeant" controversy, speaks feelingly of the lack of encouragement which he received from his superiors in this respect. Is there not here a lesson for every man holding a supervisory position, even though he is only a gang foreman? In the latter case there are quite likely to be ambitious men or young men working for him who are sadly in need of a bit of help and encouragement in getting a larger appreciation of the possibilities which lie before them and the best ways in which to prepare themselves to make the most of their opportunities.

Our advertising pages

One of the men quoted in the article on the "Bill Brown-Top Sergeant" controversy pokes fun at "Bill Brown" because of the statement that he made in commenting upon the necessity of reading the *Railway Mechanical Engineer*, and the Railway Age, that "the advertising columns alone are an education." It seems hardly necessary to comment upon this statement and yet our attitude might be misunderstood if we allowed it to go unquestioned. There was a time not so many years ago that the advertisers used only small space, seldom changed their copy and the advertising pages were little more than a directory. Today, however, many of the advertisers spend much time and money in securing accurate data and illustrations to show the working and advantages of their products, change the copy with each issue and use large spaces, that it may be effectively displayed. We have received many letters from readers of the *Railway Mechanical Engineer*—including three railroad presidents within recent months—commenting on the practical information contained in the advertisements and their helpfulness and value. In other words, "Bill Brown's" statement is typical of a large number of similar expressions which have come to us unsolicited. Sometimes, indeed, the editors have been a bit embarrassed because they have been informed that some of the readers, at least, turn first to the advertising pages when they take the wrappers off their copies.

The task of the mechanical department officer

The average mechanical department officer is perhaps more apt to consider his job as one primarily concerned with machines, material and men, taken in the order named, than anything else. It is an inspiration, however, to get another view, in which this order has been reversed, which was brought out in a talk made by the head of the mechanical department of a large western railroad at a meeting of his staff a number of months ago. In his remarks the ideal of rendering service was specially emphasized and we can do no better in passing this ideal along to others than by quoting directly a portion of his talk which is as follows:

"The most fundamental task of the officer in charge is to awaken, without any semblance of personal self-gain, an interest in and a desire for knowledge and self-development in those he has jurisdiction over. In considering this question, the officers in charge of this department are chiefly concerned in dealing with and studying this subject with respect to incentives, rewards, jealousies, rivalries, discontents, loyalties, ambitions, and aspirations. Our vice-president is primarily concerned in determining motives, intentions and responsibility. Our president is primarily concerned with relative values and the means to make real the highest values in each of us, . . . with a single motive in mind: the good of the great transportation system we are privileged to serve. When all is said and done, we cannot accept any account, any description or explanation of our combined effort which leaves out of the picture this all important aspect that we call impulse, desire, striving towards a goal. . . . Let our aim for the future be one of enlarged viewpoint, free of every small and selfish contact with only one purpose in mind to render as nearly perfect a service as possible, based on the highest principles of attainment in every respect.

"No man can be so much of a man, in any one direction,

as when he is a whole man in that direction. The fellow who can concentrate his whole being, all his energies and all his capabilities, for the compassing of the one thing on which his mind is fixed, is obviously more effective, in behalf of that object of his endeavor, than would be possible were his energies divided, and were only a portion of himself given up to that for which he is striving. And this power of concentration is that which makes the preeminent practical efficiency in any sphere of human endeavor."

This idea of the fundamental task of the mechanical department officer is old in many respects, but we find it presented here from a new angle. Its application, however, is not necessarily limited to the mechanical department. Any man who has charge of the work of other men can profit by the suggestion—first of all, aim to render service and finally know how to concentrate.

A bundle of sticks

Many years ago, the father of several sons, calling them before him shortly before his death, is said to have presented to them a bundle of sticks snugly bound together and to have asked each in turn to break them. Each in turn failed. The father then, removing the bond which held the bundle together and taking the sticks one at a time, broke all of them. This simple object lesson, presented to show the importance to the sons of maintaining family unity, is suggestive of the importance of unity and cohesion in many other situations and, perhaps, in none more than in the mechanical department budget for capital expenditures. A budget made up of numerous unrelated items for a new machine tool here, a new ash pit there and the extension of a few roundhouse stalls elsewhere may be compared to the sticks in the bundle after the cord which bound them had been removed. Each item must be defended separately and no matter what possibilities it offers for savings in the unit costs of detail operations, it is extremely difficult to prove its indispensability. On the other hand, a budget which represents a well-considered plan, perhaps looking a decade into the future as well as considering the immediate needs, carefully co-ordinated and spread over a period of years, at the end of which a definite reduction in the maintenance cost per locomotive or car-mile may be expected, the aggregate of which will show in improved net operating income, provides each item with the support of all of the others, just as each of the sticks in the bundle added to the strength of all of the others. A ten million dollar plan, for which results may be predicted in terms which mean something to the executive, is stronger than a succession of one hundred thousand dollar budgets each made up of poorly correlated items, the savings from one of which are large enough to be found when carried through to net operating income.

What are your machine tools doing?

The mechanical department of an eastern railroad has just completed the installation of new machine tools and equipment in nine of its shops. The past record of this road bears out the statement of the department head that "the procurement of this new equipment is in line with the well established practice of this road to retire equipment as it becomes inefficient and obsolete, and to replace it with modern, up-to-date equipment." He also says that, "the shops on this road are operated on a piece-work basis and the system is such that it quickly develops any inefficiency in machine tools." Our attention is called to a new 90-in. journal turning and quartering machine installed in a locomotive repair shop. Previous to the installation of the new machine, an old driving wheel lathe that had been altered and reassembled was used as a journal turning lathe. The work done on this old machine was generally unsatisfactory and expensive. The output of the machine was limited and quite often the shop management found it necessary to allow journals and crank pins to remain in service that should have been reconditioned. The fact that the shop was not properly equipped to turn journals and crank pins and keep them in proper quarter often resulted in locomotives being sent out of the shop in unsatisfactory condition, necessitating increased expenditure for repairs at the enginehouses and resulting in unsatisfactory performance of the locomotives on the road. The new machine will keep the journals and crank pins properly trued up and in quarter on all the locomotives that go through this shop, which has an output of approximately 30 locomotives a month.

Proper and adequate records of the production of all your machine tools will show when a tool is failing to meet requirements. To keep a machine tool in service that retards shop production or with which it is impossible to do the right kind of work is an expensive investment for any road. It pays to know what your machine tools are doing.

Help the younger men

One cannot but be impressed by the remarkable changes that have taken place in the railway mechanical field during the past decade. It is difficult even at this time to understand the full significance of these changes or to see them in their proper perspective. Have some of these developments made us lose sight of the necessity of helping and training the younger men to prepare themselves for the larger responsibilities which they must assume in the future? Industry and transportation have been growing at an extremely rapid pace and the problems of organization have been becoming more and more complicated. There is every sign, indeed, that these problems will continue to increase in number and extent with the continued growth of the railroads and under economic pressure. This will require much bigger and better trained men in the future, not alone in supervisory positions, but among the workers as well. Are we doing all that we should to discharge our responsibilities in this matter?

It may be well to review briefly some of the general movements under way to provide better trained men and better leadership for the future. Modern apprenticeship, inspired in this country by George M. Basford and typified by the methods in vogue on the Santa Fe and the New York Central, has gradually been receiving the support of more and more mechanical department officers and a considerable number of roads are now following approved practices in this respect. Unfortunately many roads have failed to face to this question in a big way. Even on roads where the best apprenticeship methods are being followed; however, it is important that broad-gage, big-hearted officers and men should stand ready to help and encourage the young men as individuals to recognize their opportunities and to persist in studying to improve themselves. A friendly word or a pat on the back will often go a long way in putting new energy into young men who naturally sometimes grow discouraged in their work.

During the latter part of this month there will be held in Pittsburgh the third of what have become known as Younger Railroad Men's Conferences. These have been held under the direction of the Railroad Y. M. C. A., the purpose being to gather together annually for a three-day conference representative young men from different departments and different railroads in this country and

Canada. The aim is to get the younger men to recognize the importance of the railroads in our economic, social and political structure and the opportunities in this field. The fact that a strong man must be properly balanced, is presented to them in the four-fold program of the Y. M. C. A. Then, too, with the help of practical railroad officers, an effort is made to have the boys check up to see that they are in the particular branch of railroading that they are best fitted for and as to how they may best prepare themselves for advancement. The boys, on the basis of former conferences, will go back to their home towns and will help their fellows grasp the spirit of the conference and profit from it in a practical way. Then, too, these conferences in many cases have opened the eyes of railroad officers to their responsibilities and opportunities in encouraging young men and helping them to find their proper places in the organization.

That these things appeal to the practical, hard-headed railroad officer is indicated by the fact that several of the railroad clubs have inaugurated "Younger Men's Nights." Few meetings of the New York Railroad Club have attracted so great attention, for instance, as the one last month, at which seven young men from as many different railroads and as many different occupations, gave 12-minute talks in which they told something of their experiences and problems, as well as what they conceive to be the opportunities in their particular work. From these it was clearly evident that these young men are not expecting favors, but that they recognize that they must make good by hard work and real ability. What they do ask, however, is that a reasonable effort be made to give them the right kind of information and training and to help them gain a larger appreciation of what the railroads mean and how they, as individuals, can render the largest degree of service.

New Books

PROCEEDINGS OF THE INTERNATIONAL RAILWAY FUEL ASSOCIATION, 1925. *Edited by the Treasurer, J. B. Hutchinson,* 1809 *Capitol avenue, Omaha, Neb.* 526 *pages, illustrated. Price* $3.00.

This book contains the proceedings of the seventeenth annual convention of the International Railway Fuel Association which was held in Chicago, May 26 to 29, 1925. The reports submitted include boiler feedwater heaters; front ends, grates and ash pans; stationary plants; Diesel locomotives; fuel stations, and firing practice. The book also contains the following papers which were read before the convention by men in the railroad field interested in fuel conservation: Signals and the saving of fuel; How can the railroad management effect fuel economy? How can fuel purchases effect fuel economy? The development of oil burning practices on locomotives; Fundamental fuel factors; How can a mechanical officer effect fuel economy? Back pressure as an index of fuel economy, and the N. A. P. A. coal chart.

THE AIR BRAKE ASSOCIATION PROCEEDINGS, 1925. *Edited by the secretary, F. M. Nellis,* 165 *Broadway, New York.* 350 *pages, bound in leather.*

The proceedings of the thirty-second annual convention of the Air Brake Association which was held at Los Angeles, Cal., May 26-29, 1925, is the testimony of what a railway association can do in the way of constructive work through proper committee organization. The book contains an unusual amount of practical information which is due largely to the manner in which the various committees and air brake clubs handle their reports and papers. The subjects discussed at this year's convention covered practically all phases of air brake work. The reports submitted covered: What is the best material for air brake and air signal piping? Passenger train handling; Graduated release; Condemning limits of A. R. A. standard triple valve parts; What are you specifying and what are you getting in foundation brake rigging on car equipment? Brake pipe leakage; More efficient air compressors; Recommended practice; Triple valve slide valve, leakage indicator; and Automatic train control. The reports of the secretary, treasurer and various committees are also included.

PRINCIPLES OF LOCOMOTIVE OPERATION, *by Arthur Julius Wood, professor of mechanical engineering, The Pennsylvania State College.* 315 *pages, illustrated,* 6 *in. by* 9¼ *in. Bound in cloth. Published by the McGraw-Hill Book Co., Inc., New York. Price,* $3.00.

The first edition of this book, which was published under the title of the "Principles of Locomotive Operation and Train Control," has been used quite extensively as a text book in technical schools and as a reference book by many railway mechanical department officers. This, the second edition, is a worthy successor of its predecessor for the author has included in its revision the most recent developments, both theoretical and practical, in the design and construction of the steam locomotive. Prof. Wood has shown the locomotive as a power plant to which the maximum possible amount of energy in the fuel should be available at the drawbar. The application of the laws of mechanics and thermodynamics are brought out by a number of practical examples which point the way to a solution of the more involved problems in proportioning and design.

It is well for those who are being initiated into the mysteries of the locomotive to consider at the outset the application of the fundamental laws of mechanics as applied to locomotive design and operation. Hence, the book begins by defining the purpose of a locomotive in terms of these laws. The purpose of a locomotive is to do work. Work is the overcoming of resistance through space and is, therefore, the product of the two quantities; namely, a force, and the distance through which the force acts. The utilization of heat energy for the performance of useful work and the various changes through which it must go in order to perform useful work at the drawbar, are discussed in the introductory chapter. The author's method of handling these fundamentals of locomotive design and operation cannot help but refresh the mind of the student who has already studied his thermodynamics and mechanics.

Railway mechanical department officers will find this book to be a valuable addition to their reference libraries. The arrangement of the book is such as to provide quick access to information on the various subjects incidental to locomotive design, construction and operation. A list of the chapter headings and a few of the sub-divisions in each chapter will give the reader some measure of the thoroughness with which the author has covered the subject. These are as follows: Principal Types of Locomotives; Determining the Tractive Force for Two and Three-cylinder Locomotives; Acceleration of Trains; Train Resistance; Effect of Air and Temperature on Resistance; Curve Resistance; Speed-Time Curves as Applied to Locomotive Performance; Dynamometer Cars and Tonnage Rating; Air Brakes and Brake Rigging; Combustion and Fuel Economy; The Formation and Action of Saturated and Superheated Steam; Valve Motion; Locomotive Ratios or Factors; The Proper Selection and Use of Locomotive Ratios; Counterbalancing; Locomotive Testing; Modernizing the Locomotive. The book also contains an

appendix in which is given a number of convenient tables for use in design and calculation.

The chapter on tractive force includes a discussion of the effect of inertia of reciprocating parts, and the effect of speed on the tractive force developed by a locomotive. In showing the development of the Kiesel formula for calculating the cylinder tractive force for saturated locomotives, the author has supplied constants that may be substituted in this formula when determining the tractive force of superheated locomotives. These constants are intended to eliminate the usual difficulty encountered in determining the true average rate of evaporation and the effect of the superheater surface. This chapter also discusses the various factors entering into the calculation of the tractive force for three-cylinder, four-cylinder compound, Mallet four-cylinder compound, and for locomotives equipped with boosters.

In the revision of the text, a number of problems have been added on the design of foundation brake rigging, a discussion of the time lost in slow-downs and descriptions of the latest developments in stokers, feedwater heaters, brick arches and boosters. There is also included a method for laying out a Walschaert valve gear; factors and ratios for empirical design; a discussion of the theory of steam locomotive development; calculations for counterbalancing, and a discussion on modernizing the locomotive. The chapter on the formation and action of steam has been entirely rewritten and includes the most recent data on boiler performance.

While intended primarily for use in technical schools, this book furnishes railway engineers and officers interested in locomotive design and operation a concise review of the theory on which certain problems in locomotive design and construction are based. In revising and bringing up-to-date his original work, the author has fulfilled the wishes of many mechanical department officers.

What Our Readers Think

Locomotive efficiency—Past and present

GALVESTON, TEX.

TO THE EDITOR:

I have been quite interested in reading the editorial entitled "Locomotive efficiency improves," in the September issue of the *Railway Mechanical Engineer.*

Surely the writer of the editorial does not mean to intimate that a drawbar pull of 22,078 lb. represents the maximum capacity of the Pennsylvania 2-8-0 locomotives of Class H-6-A. If he will turn to page 141 of the book, "Locomotive Tests and Exhibits," issued by the Pennsylvania, the following significant statement will be found: "Higher drawbar pulls were not obtained because at slow speeds and long cut-offs there was constant danger of stalling the brakes and slipping the drivers, owing to the fluctuations of the pressure of the water used for controlling the brakes."

Since the testing plant has been moved to Altoona, these limitations have not applied and, therefore, the maximum drawbar pulls obtained at present are by no means comparable with those registered at St. Louis.

If it is desired to compare the most advanced locomotive practice of today with that of 21 years ago, solely on a basis of fuel economy and general efficiency, why ignore the performance recorded by the Michigan Central locomotive No. 585 on the St. Louis plant? This locomotive, despite its limitations in other respects and notwithstanding the fact that it possessed but few of the fuel-saving refinements which are now found so essential, need not fear comparison with today's best machines on an efficiency basis.

Michigan Central cross-compound 2-8-0 locomotive No. 585

	Maximum	Minimum
Dry coal per d. h.p. hr., lb.	3.61	2.14
Boiler efficiency, per cent	78.42	49.81
Machine efficiency, per cent	94.16	74.98
Locomotive efficiency, per cent	8.04	4.80

WM. T. HOECKER.

The evaporative capacity of locomotives

BURNHAM, PA.

TO THE EDITOR:

In his rather elaborate study of the evaporation in locomotive boilers in the August and September issues of the *Railway Mechanical Engineer,* Mr. Poperev criticizes the accuracy of some methods I have used in analyzing tests of locomotive boilers. May I suggest that before this criticism is taken too seriously, careful consideration be given to the purposes for which my methods were developed and also to the rather antiquated foundation on which two out of three of Mr. Poperev's elaborate equations are built.

In studying the relation between steam produced and coal used, I have shown that within the range of experimental results available, the boiler efficiency if plotted against the rate of firing follows closely a straight line relation. In a recent account* of the use of this relation I wrote—

> This method of plotting boiler efficiency against rate of firing is of considerable value in the study of locomotive operation. In all tests of coal burning locomotives that the writer has examined the straight line relation between boiler efficiency and rate of firing is characteristic. It does not seem possible to connect this straight line relation to any fundamental laws, but experience shows that as an empiric rule it can be safely counted on.

Mr. Poperev states that there are "convincing reasons for doubting the correctness of the method accepted by Mr. Fry," but he shows nothing which contradicts the statement above. His only criticism is that for very low rates of evaporation the straight line relation will not hold. Theoretically the point is well taken, but it has little practical importance as the rates of evaporation at which the relation departs perceptibly from a straight line are lower than occur in any tests available and much lower than are met with in practice. Within the range of working covered by the tests, the complicated hyperbolic curve for boiler efficiency chosen by Mr. Poperev flattens out so much that for all practical purposes it is indistinguishable from a straight line. Since there is no advantage given by the more complicated curve at normal rates of evaporation, it is preferable to use the straight line on account of its simplicity and the ease of determining the constants corresponding to any given set of test results.

Apart from the increase in complication without a corresponding increase in practical accuracy, further criticism of the Poperev equations may be made on the score that too broad a generalization is attempted from too narrow a body of data.

It is shown that the relation between equivalent evaporation and the rate of firing can be closely approximated by an equation of the form—

$$Ze = a + bY + cY^2 \text{ ——— } (1)$$

Where Ze is the equivalent evaporation per sq. ft. of heating surface per hour, Y is the rate of firing in pounds

* A Study of the Locomotive Boiler, by Lawford H. Fry, page 46.

of dry coal per sq. ft. of grade per hour and where *a* is a constant and *b* and *c* are coefficients dependent on the boiler design and quality of fuel.

Three groups of equations are given by Mr. Poperev for determining the values of *b* and *c* from the boiler dimensions and the heating value of the coal. The number of boiler tests in each group is as follows:

1—For boilers using bituminous coal with firebrick arch, seven tests.
2—For boilers using semi-bituminous coal with firebrick arch, six tests.
3—For boilers using semi-bituminous coal without firebrick arch, six tests.

Now as far as the equations in groups 2 and 3 are concerned, it should be noted that the semi-bituminous coal used was of a type shown by the tests to be poorly adapted to locomotive use, and none of the boilers had superheaters or combustion chambers, so that the tests are not representative of modern practice. The boilers and coals of the tests in group 1 are representative of good current practice, and probably the coefficients given are applicable to the seven tests in this group, although very little direct evidence as to this is offered. It is highly questionable though whether the equations given for determining the coefficients are generally applicable to boilers of other designs. The only two variables taken into account in these equations are the heating value of the coal and the ratio of evaporative surface to grate area. Very little study of tests made on locomotive boilers is required to show that these two variables are entirely inadequate to characterize completely the operation of any given boiler. Boiler efficiency can only be studied properly if it is separated into its two components, i.e., efficiency of combustion and heat production, and efficiency of heat absorption. The efficiency of heat production will be affected not only by the ratio of heating surface to grate and by the heating value of the coal, but also by the amount of air admitted to the firebox, by the relative volume of the firebox, by the size in which the coal is fired, and by the method of firing, whether hand or stoker, and further by the efficiency with which the firing is done which is determined by the skill of the firemen and also in the case of a stoker by the type of stoker. The efficiency of heat absorption will depend on the firebox temperature, on the relation of firebox surface to flue surface and on the length and diameter of the flues.

It will be seen that the equations proposed by Mr. Poperev leave out of account a number of factors of major importance and can, therefore, hardly claim to be based on fundamentally correct principles.

LAWFORD H. FRY.

Another comment on evaporative capacity

CHICAGO, ILL.

TO THE EDITOR:

The only reliable literature on the subject of locomotive boiler evaporation is based on testing plant or standing tests, during which all factors entering into the test can be ascertained in weight or measurement by accurate apparatus and handling. So-called tests made on the road are of the roughest approximation of accuracy, due to the exigencies of service and the complication of the mixing in of the engine and the auxiliary appliances, steam requirements and performance. Locomotives, however, are not built for testing plant service but for road service, which may account for the numerous and varied tests made.

In Mr. Poperev's article on the evaporative capacity of locomotive boilers which was published in the August and September issues of the *Railway Mechanical Engineer*, the formulas all contain constants based on "given" boiler and fuel. Fuel variations are bad enough. I was at one time an officer of a railroad on which the finest steam coal mined in this country was handled in vast quantities, yet we had so-called "bad coal failures" as on other roads.

The dimensions and arrangement of the boilers under consideration are likewise under "given" limitations, set up largely by the personal factors of the designers. The very important ratio of grate area to heating surface, as shown in Table 1, page 549, of the September issue, on a considerable number of locomotives, originated mainly on one road, ranged almost two to one.

The expression, "total heating surface" does not mean much; does not convey with any accuracy the heat transfer value per sq. ft. A large percentage of the flue and tube heating surface is of relatively low value. With a given firebox, one boiler may have 15-ft flues and another, due to wheel arrangement requirements, may have 20-ft. flues; but the five additional feet are of no real evaporative value, although taken in the formulas as of average value.

It is possible to find an equated value to cover the evaporation of tubes and flues for any length, size and spacing from fairly well established tables as used in locomotive design. If such values are deduced in terms of firebox evaporation and added thereto, it will give an expression of the real amount of heating surface on equivalent basis of evaporation for the boiler as a whole.

I also want to take exception to the omission of superheating surface in such formulas. The locomotive is a heat engine and all heat developed on the grates and the total heat as measured when steam is released for duty should be credited in the performance and expressed in the boiler efficiency. In a recently published test, the heat transfer across superheating surface was approximately 11 per cent of the total transfer of heat output to steam.

What has been said is not with the idea of evolving a formula, but to advance some practical considerations in boiler performance to assist the mathematicians in clearing up some debatable features of the constants employed.

C. A. SELEY
Consulting Engineer, Locomotive Firebox Company.

Encouragement from a reader

EL PASO, TEXAS.

TO THE EDITOR:

For several years I have been a reader of the *Railway Mechanical Engineer* and now want to express my admiration of the persistence with which you have tried to impress on the railway public the necessity and importance of apprentice training. As an apprentice and since finishing my apprenticeship, I have been interested in the articles appearing in your magazine on the above subject. They have been of a constructive nature at all times. The articles written by the apprentices have been particularly interesting in that they show that worth-while boys are taking an interest in their training.

To my mind, the biggest factor in apprentice training is to use the best judgment possible in hiring the boys. Then do the utmost in making finished artisans of them. So many times haphazard methods are used in choosing boys that it is no wonder that a poor-class of mechanics is the result. The returns paid on such an investment, in a boy in training, cannot be estimated and, from a selfish viewpoint it is incumbent on the railroads to give more time and thought to hiring as well as to training apprentices. ASSISTANT ENGINEHOUSE FOREMAN.

The making of a railroad officer*

FOR a long time there has been an insistent demand for a book on leadership, particularly directed or applied to the needs of the railway field. As the responsibilities of railway officers and foremen have increased and extended and the duties have grown more and more exacting, these men have been on the look-out for information that would help them to take advantage of the best thought on how they might improve their leadership ability. There have been hundreds of books and thousands of articles published in recent years on the art of management and personnel administration. These are rather high sounding terms for the busy foreman or officer who is constantly being crowded for results, who often has far more men under his direction that he should have according to the best practices, and who in many cases on a railroad has the forces scattered over a large area. Unfortunately most of these books and many of the articles have lived up to these high sounding terms, and it has been extremely difficult for the average man to study them with any great degree of enthusiasm, or, indeed, to profit much from them. Then there is a great group of younger men in railroad organizations who have been trying to find some way of preparing themselves for promotion.

A successful railroad officer who early recognized this need and who possessed more than ordinary powers of observation and had had unusual success both as a leader and in developing the men under him was finally inspired to prepare a book particularly directed to the needs of railroad officers, foremen and ambitious workers. While Mr. Woodruff, the author, clearly outlines the principles of good organization and successful leadership, it is not done in the usual text-book fashion, or in the cold formal manner adopted by writers of technical books. Rather, Mr. Woodruff has thrown into the book much of his energetic, enthusiastic, constructive personality and we find the statement of principles backed up by, or even included in, interesting observations and personal experiences. This makes the book easy to read and study.

The book covers a wide range, as is clearly indicated by the chapter headings which follow, but on the other hand it is accompanied not only by a complete index, but the table of contents includes under each chapter heading a comprehensive synopsis by listing the subheadings. Moreover, to facilitate reference, the subheadings are printed in bold face type, so that they can readily be located. The chapter headings are: Why This Book; Service; Co-operation; Study of Human Nature, followed by five chapters relating to the study of profiles, heads and other distinctive types; Differences Between Men and Women; Expression or General Appearance; Employment; Psychology and Memory; Job Analysis; Planning the Work; Organizing the Work; Treatment of Men; Cost Studies; Charting Statistics; Elimination of Emergencies; Safety; Public Speaking; Further Application of Salesmanship Principles; Ethics of Railroading; Staff Teamwork; and Personal Application.

In commenting upon the book and its table of contents the Railway Age recently said:

"These are only a very few of the subjects covered, but they are perhaps sufficient to give an idea of the range of the work. And the author bases all his principles and generalizations on definite instances which have arisen in his experience. This keeps the subject from soaring above the head of the literal-minded reader and also serves to make his recommendations specific. There will doubtless be differences of opinion concerning some of his statements, but if one should write a book covering this field and include in it only those principles on which there is general agreement, the book would be so elementary as to lose its value outside the kindergarten. Too many books dealing with the technique of various occupations have stumbled into this fault, and it is encouraging to see this author avoid it even at the expense of arousing some criticism on the part of those who will not agree with all his conclusions.

"But this quality makes the work of value to railroad officers who have already 'arrived'—persons who could not possibly be interested in it otherwise. These readers will look at the work not so much as an authority telling them how to succeed—they have already done that—but rather as a collection of intelligent observations and comments by one of their own kind, with whom they may differ as they see fit.

"Readers of this calibre—and probably many of the younger men too—will, we believe, question the length to which the author goes in placing his trust in the so-called 'science of character analysis,' whereby it is believed possible to lay down definite rules concerning the characteristics of men according as they are blondes, brunettes, high-browed or lantern-jawed, and so on. The author is perfectly honest about it and says in a footnote that the possibility of so arriving at an approximation of character is questioned. But even if it is possible to arrive at accurate conclusions from the observations of features, the fact remains that it is a task for experts. It is probably true to say that, other things being equal, blondes are thus and so. But other things are *not* equal. A skilled character analyst knows this and is careful to weigh all the factors obtainable, but even then his estimates are not always free from error. It is doubtful whether the author can successfully inculcate sufficient knowledge of the subject in his brief treatment of it to make his readers expert therein. They must, therefore, look upon his statements merely as introductory to the subject and await further study and richer experience before they begin dogmatically to judge their fellows with these rules."

A book of this sort can not only be read and studied to excellent advantage and profit by the individual, but it can also be used with good results for group study or in connection with club or open forum discussions and will undoubtedly find a large field of usefulness in this way. Mr. Woodruff has placed the railway world under deep obligations to him by recognizing and filling in so acceptable a manner one of the greatest needs of the present day.

*The Making of a Railroad Officer, by R. E. Woodruff, superintendent of the Erie Railroad. 244 pages, 5 in. by 7¼ in., bound in cloth. Published by the Simmons-Boardman Publishing Company, 30 Church street, New York. Price $2.00.

DURING THE YEAR 1924 the Canadian railways paid salaries and wages amounting to $239,864,265, a decrease from the previous year of over $13,000,000. The number of freight cars in service was 226,163 with a total capacity of 8,283,264 tons, or an average capacity of over 36 tons. Passenger train cars totaled 6,849. There were 5,857 locomotives in service, including 29 electric. The total fuel consumed was 9,307,372 tons at a cost of $51,279,428. The consumption of ties totaled 14,294,416 at a cost of $13,216,-325.34.

GOOD HEALTH PROFITABLE ALL AROUND.—Dr. M. R. Taylor (quoted at the National Safety Council convention at Cleveland) in discussing the stimulation of production, said: "The modern employer has come to realize that the human machine pays a far larger return on the investment in its upkeep than any piece of iron or steel ever can or will. Physical health is man's greatest asset; and as this is true individually, it must be true collectively; therefore, the capitalizing of it should become a consequential factor in all industries. A well-organized industrial medical department should be as beneficial to the employer as to the employee."

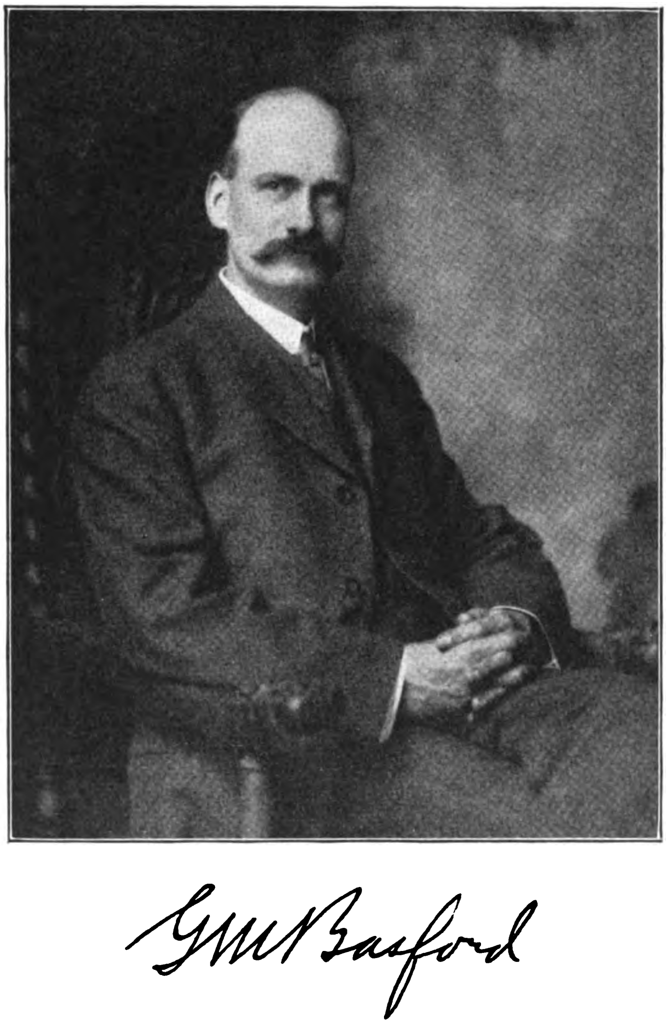
George M. Basford passes away

Former editor of this journal—Noted mechanical and signal engineer and technical publicist

GEORGE M. BASFORD dropped dead in the Jerome avenue subway station in New York City on Monday evening, October 26. Funeral services were held in Mount Vernon, N. Y., on Wednesday evening, and the interment will be at Boston on the return of Mrs. Basford from abroad.

During the early years of the present century this publication, then the American Engineer and Railroad Journal, was familiarly known among its readers as "Basford's paper." He was a fitting successor in its editorship to M. N. Forney, who had exerted so great an influence upon the upbuilding of American railroads. It is not surprising that the readers recognized it as "Basford's paper," because for a number of years he carried almost the entire burden of editing it, exerting a strong leadership in mechanical department affairs and gathering around him as counsellors the outstanding and most constructive men in the railway mechanical field. This significant statement was made when he laid down the editorship in the fall of 1905: "Mr. Basford has fought the battle of the motive power department, consistently and systematically maintaining that it should be properly and fittingly recognized because of its real importance in the organization of railroads."

The locomotive made a special appeal to Mr. Basford from his boyhood days, and without question he has had a larger influence upon the development of the modern steam locomotive than any other one man. Not that he ever patented or perfected any detail of locomotive design; but rather because of his keen engineering ability, and his vision and realization of the possibilities of the locomotive. He was constantly suggesting to the designers as individuals, or to the readers of this publication when he was an editor, what steps could best be taken to improve and develop it. He was, for instance, quick to recognize the possibilities of the application of the superheater, the Walschaert valve gear, the feed-water heater and many other special devices or new features of general design. He enthusiastically advocated such improvements in season and out of season and he encouraged designers and builders to experiment with them until they were finally perfected and came into general use. More than this, he recognized the importance of a larger utilization of the locomotive and did much to encourage the analysis and study of locomotive operation in order to determine just how this could best be accomplished.



For a few years before taking up editorial work he was a signal engineer and this experience and a study of the economics of signaling, led him to recognize in even a greater degree, the possibilities of a maximum utilization of the locomotives and track, resulting in more efficient and economical operation. Mr. Basford was always an enthusiastic advocate of railroad and technical associations because he recognized the inspiration and help that men receive from getting together and comparing notes and pooling experiences. "There is no reason," he used to say, "why an editor should not occupy a place of constructive leadership if he locates and keeps in touch with the leaders in specific fields. By getting around among these men, the editor, on the basis of their combined experiences, should keep ahead and be a great help to any one or all of them." It was a realization of the value of exchanging and combining experiences that caused him to get his fellows in the signal field to organize the Railway Signaling Club, later the Railway Signal Association, and now the Signal Section of the American Railway Association. He was familiarly known as the "father" of that organization and continued throughout his life to take an active interest in it, although in later years his work led him at times almost entirely into other fields of activity.

It hardly seems possible now that only a comparatively few years ago mechanical engineers felt that they were not concerned with questions of management and the human element; that their field was concerned more with materials and methods. Even in such an outstanding

organization as the American Society of Mechanical Engineers, it required a hard fight on the part of the more progressive members to have a consideration of these matters included in its program. Mr. Basford was among those who early recognized the importance of the human factor in industry and in the railroad service. He saw the railroads growing larger and more important, the cars and locomotives increasing in size and capacity and the problems of operation and maintenance growing more and more complicated, and was deeply concerned with the education and training of leaders who could maintain this progress and direct it along the right lines. He recognized the great waste of effort and energy caused by lack of adequate leadership and lack of training and education on the part of both the supervisors and the workers. The seriousness of this problem grew more and more on his mind and resulted in his paper on "The Technical Education of Railroad employees—The Men of the Future," which was presented at the American Railway Master Mechanics' Association in 1905. It was this paper more than anything else, that awakened the mechanical department officers to the necessity of giving greater attention to the selection and training of the workers. It was directly responsible for the inauguration of modern apprenticeship systems on the Santa Fe and the New York Central. It is doubtful if even Mr. Basford's most intimate friends understood the tremendous effort and the infinite pains that he took in preparing this treatise, submitting it before it was put into its final shape to many of the leaders in the railroad world at that time, including men like E. H. Harriman and James J. Hill. In commenting on this paper the Railway Age Gazette, now the Railway Age, said in its issue of March 14, 1913:

"The preparation of this paper might well be studied by young men who are ambitious to make their efforts felt in the railway field, and it affords a marked contrast to some of the papers and reports which are often presented before railway clubs and technical associations. It was the result of years of study of conditions on the railroads in this country and a practical experience in mechanical department work. Foreign methods had been carefully looked over on his trip abroad and then the whole scheme was carefully planned and outlined. The paper was then drafted roughly and was rewritten and rewritten until every sentence was carefully rounded out and every superfluous word removed, so that the thought was clear and forceful throughout. It was then submitted for criticism to a number of leading railway officers and industrial managers, and their comments were carefully considered in its revision, although it may truthfully be said that such revision as was made was very slight indeed. And dominating it all was a broad spirit of fellowship for his fellow man, which is so characteristic of Mr. Basford. It is little wonder that it marked the real cornerstone of railway apprenticeship education in this country, and it is to be regretted that more railroads have not adopted and lived up to its spirit."

Mr. Basford was constantly on the look-out for the opportunity of inspiring and helping promising young men, in order that they might better prepare themselves for making the best possible use of their talents. No sacrifice of time or energy was too great to make for those who called upon him for advice or assistance. The latch string of his office was always on the outside and there has been a constant stream of young men, and older men, too, going to him for advice and inspiration. He proved to be a haven in times of stress; indeed, at times when his personal problems were giving him the deepest concern and seemed to be about all that he could bear, he would be found temporarily laying them aside in order to help someone in distress. It is not surprising, therefore, that in 1903 a large number of his friends, realizing that he himself was greatly in need of relaxation and encouragement, united to send him abroad with his wife for a number of months. Even then he insisted on keeping in the harness and the valuable record of his impressions of foreign railway practice represented appreciation for the tribute that his friends paid to him.

It is difficult to recognize in a proper way the great influence which Mr. Basford had on raising the standards and value of the advertisements in the technical press. His long engineering and editorial service, his broad training and large vision, supplemented by experience in salesmanship, brought a new force to bear when he entered the advertising field. It is a far cry from the day when advertisers changed their copy only once or twice a year and ran little more than a card, to these days when advertising copy is changed in every issue and advertisers go to great expense to secure that kind of copy which not only possesses a strong educational value, but specifically aims to give the possible user of the device or material accurate information about the functioning of the device and how it may best be utilized, with concrete information as to its advantages. Mr. Basford's ideal was to rival the editor in making the advertising pages so instructive and interesting that the reader would turn to them first on opening his paper. That he and others who caught this same vision have achieved a large degree of success, is widely recognized.

Mr. Basford was constantly being approached for advice by officers and subjects committees of the different railroad associations and clubs, and not a few programs of the most successful conventions and club meetings have been due to the help that he gave, remaining, however, usually in the background. The records of these organizations over a period of years contain a considerable number of his addresses, every one of which was prepared with the greatest care, being presented only after he had painstakingly revised and reviewed them a number of times.

Mr. Basford was born in Boston in 1865, where he attended the public schools. He was graduated from the Massachusetts Institute of Technology in 1889, after which he entered the Charlestown shops of the Boston & Maine, later going to the Chicago, Burlington & Quincy as a draftsman at Aurora, Ill. He left the Burlington to take a position in the motive power department of the Union Pacific, and was connected with the test department of that road for some time, after which he entered the service of the Chicago, Milwaukee & St. Paul as signal engineer. Later he was superintendent of construction of the Johnson Railroad Signal Company, was with the Union Switch & Signal Company for a short time, and then became signal engineer of the Hall Signal Company. In 1895 he became mechanical department editor of the Railway and Engineering Review, and in 1897 was made editor of the American Engineer and Railroad Journal, now the *Railway Mechanical Engineer*. In September, 1905, he was made assistant to the president of the American Locomotive Company. It was during this period that for a number of months he was called upon to give part of his time in helping to start the Railway Business Association, rendering exceedingly effectual and much appreciated service. In March, 1913, he became chief engineer of the railroad department of Joseph T. Ryerson & Son. Mr. Basford organized the G. M. Basford Company to handle technical advertising in March, 1916. At about this time he was also made president of the newly organized Locomotive Feedwater Heater Company and headed it for several years until it was taken over by the Superheater Company. He was also consulting engineer of the Lima Locomotive Works, Inc.

"Bill Brown" and "Top Sergeant"

"Bill Brown's" policies and the editors of this publication are both severely criticized

THE *Railway Mechanical Engineer* had no idea when it announced the competition on the responsibilities and opportunities of the foreman that it was going to start a lively controversy, the participants in which would not be too busy in their efforts to belabor each other to toss a few brick-bats at the editor.

A few days before going to press we received a letter from the head of one of the mechanical departments as follows:

"There is a Scotch couplet that goes something like this:

'O wad some power the giftie gie us,
To see oursel's as other's see us!'

"With this thought in mind, I am attaching a copy of a letter sent me by one of our inspectors. It is interesting in more senses than one, but as it furnishes food for thought to the editor of the paper presenting the prizes, it has occurred to me it would be of special interest to you."

The article which accompanied the letter gives "Bill Brown" as well as the editors something to think about. We can see "Bill" grin as he reads the following extracts from this letter—or possibly he may be getting worried over some of the things that are being said about him.

Ridicules "Bill Brown's" article

"In the first place, were the article of intrinsic worth, surely a *nom de plume* would not be considered necessary. That in itself proclaims its greatest weakness and creates a doubt in my mind as to the genuineness of "Bill Brown."

"*The new foreman.*—Today in most shops time is figured out down to the fraction of a cent and the opportunity for calling all the men away from their respective machines for no other reason than to say, 'I have been made foreman' and to offer excuses—as one might reasonably interpret 'Bill's' remarks—is hardly to be expected. When a man is made foreman, be he stranger or otherwise, his actions from the start should be his introduction to the men. Let him realize that he is but one step ahead of the journeyman under him. It does not always follow that to be a successful foreman one must be the best mechanic; other qualifications just as important are very necessary and possibly it was for these he was chosen. The journeyman's ideas are often best and should be considered. I will agree with 'Bill' that the day of the hard-boiled driver is past. He was an abomination and his real efficiency was usually a minus quantity. The educational standards of our country today are such that the average mechanic is usually found to have a high grade of intelligence and as such should be respected. 'Bill Brown' by his patronizing tone would seem to ignore this point.

"*Keep posted about railway affairs.*—In his article 'Bill' surely allows his fancy to take a wonderful flight. He says, 'Give half an hour each night to the columns of *Railway Mechanical Engineer* and the Railway Age and he will become fairly well posted on such all-important subjects as operating ratios, fuel saving, taxation, rates, etc.' The idea of a machine shop foreman becoming fluent enough to discuss in an educational way the above topics and staying a mere foreman when such a knowledge of any one of them would offer its possessor a salaried position far in excess of 'Bill's,' is hardly understandable. I doubt very much if one could assimilate all this knowledge from periodicals. I feel that to devote a half hour each evening to furthering one's knowledge of his own particular brand of the work would be productive of greater results, not only to the employee, but also to the employer. Periodicals make light reading, interesting too, but as a usual thing eventually forgotten. As for the advertising columns, the maker and vender of each article claims its superiority over all others and to obtain an education through these channels would be out of the question. That was a rare flight of 'Bill's.'

"*Treatment of new employees.*—The new man is, as a general rule, anxious to make good, and I agree that his ultimate success lies in no small measure with his immediate foreman. The cost of labor turnover in some of our large shops is excessive and can only be written off by the employers as a total and, in the majority of cases, unnecessary loss. A proper study of human nature and the ability to strengthen the weak points of the new man, and place him where he is best fitted, would do much to lessen this item of expenditure and enhance not only the foreman's value, but also that of his men, in the eyes of the employer.

"'Bill Brown' mentions the fraternal pin. I disagree with his views on this. Experience has shown the writer that it is best to keep fraternal 'pull' out of a business such as 'Brown's.' Fraternalism and all it applies is one of the finest principles of our everyday life, in its proper place, and that to my mind is after working hours. To countenance any one 'pin' in the shop is to drive a wedge in your armor by the opposition, which is always to be found, and a consequent reduction in the general efficiency of a shop is the result.

"*New tools or machinery.*—When 'Bill' wrote this article his fancy was in the clouds, only to come to earth long enough to boost the *Railway Mechanical Engineer* and its advertising columns. He stepped blithely into the shoes of the master mechanic or superintendent and declared it most inexcusable for any foreman not to do so. A nice dream, but certainly neither practical nor educational.

"*The sales engineer.*—I will agree with 'Bill' that very often one can learn pointers from the sales engineers. More often than not they are practical men who have had shop training. One point, however, I cannot let go. He states that he has often been obliged (gladly) to work extra hours because of having spent some of his time during the day investigating their claims of devices. This statement sounds weak. In the first place, as a foreman, he was neglecting his duties during the working hours. Second, it is my belief that the average sales engineer is physically unable to carry around working samples of his wares.

"*Attitude toward apprentices.*—In part I agree with 'Bill' here. He is inclined perhaps to be too big-hearted, but a study of the human element would have to be the foreman's guide. No set practice can be employed.

"In summing up the entire article, I feel that 'Bill Brown' has hardly propounded any really practical views as to the duties of a foreman, but rather he has skimmed airily over these responsibilities with what is merely a

treatise on etiquette as he thinks it should be practiced in a machine shop, without giving thought to some of its impossibilities. The field of foremanship, especially with railroads, is too broad to be narrowed down within 'Bill Brown's' evident limits and it is hard to understand why a periodical of the status of the *Railway Mechanical Engineer* should laud and broadcast his views as being an outstanding example. Its paucity of detail, its impracticability, serves but to create an attitude of condemnation and doubt as to the article's veracity."

A more constructive letter—from a reformed member of the so-called hard-boiled group, at least so he characterizes himself—follows. Incidentally it tells why some supervisors are of the hard-boiled type.

Why some foremen are hard-boiled

CHICAGO, Ill.

To the editor:

It is gratifying to a lot of us old time foremen to see the interest being taken in trying to provide better opportunities for us, and to bring to us a greater realization of the importance of our positions.

I believe the generous response to your request for a free expression of opinion regarding the controversy now being waged relative to the divergent viewpoints of "Bill Brown" and "Top Sergeant" have opened the eyes of many to the fact that a great many foremen are and have been devoting much thought to this subject.

Personally I have been a most interested reader of all the articles which have appeared and while agreeing in the main with the stand taken by "Bill Brown," I can't help having a sort of sympathy with the "Top." Having started as a foreman thirty years ago, about the same time as he did, and presumably under similar environments, I can well appreciate why he is so hard-boiled. Years ago, especially in the part of the country where I was made, it was the rule to be hard-boiled. I was about as hard-boiled as they make them, and continued that way many years until I woke up to the fact that more and better work can be gotten out of men by leading instead of driving them. "Top Sergeant" don't seem to have learned that lesson yet. Maybe the "old dog don't want to learn new tricks."

In this day of enlightenment if a man in a supervisory capacity is hard-boiled, there must be a reason for it.

I started out, as I have no doubt "Top Sergeant" did—and as most foremen do when they are first promoted—with a very exalted idea of the things I was going to accomplish. I was going to show the "Big Boss" that never before in the history of railroading had a job been handled as efficiently as I would handle mine. I was going to be absolutely fair to all the men and give each one a square deal. I was going to so organize my work that none of it should lag behind on account of any lack of foresight on my part in ordering material or routing the various operations. I was going to be a real "humdinger." But I soon had many of my exalted ideas taken out of me.

My first job as a foreman was in a round house where I was compelled to handle about three times as many engines as we had stall room or facilities for handling. I had over double the number of mechanics, with their helpers and laborers, that any one foreman could handle efficiently. In addition to this there was no up-to-date machinery and very poor store room service. But regardless of these handicaps, I was optimistic and felt that I could deliver the goods.

After spending many hours at home when I should have been sleeping I matured a plan that looked mighty good to me. It called for a slight rearrangement of working force—adding a few mechanics and cutting off some laborers. I wanted a different arrangement of the tracks in the "garden" so that I could better handle the reserve power. I wanted a couple of new machines and a better supply of stock so that I could make and put into use some home-made tools that I felt would expedite the work. So many years have elapsed that I don't remember all the details of my plan, but I have a distinct recollection that if allowed to put my ideas into effect, I felt that our costs could be cut very materially.

Why I became hard-boiled

Full of hope and optimism, I put my ideas up to the "M.M." He was one of the old school of railroad officials who had forced his way up the ladder more by virtue of an aggressive personality, than by any real mechanical knowledge, but I had full faith in my ability to make him see the value of my suggestions. He read my carefully prepared plan over to the end. Then cocking his cigar at a more aggressive angle in the corner of his mouth, and glaring over the top of his glasses at me, proceeded as follows:

"What the h—— do you think I am, a fool? After handling the work at this point for ten years under the present line up, do you think I am going to confess to the management that we need to spend all this money for new equipment?"

"But, Mr. Jones, I thought—"

"To h—— with you, and your thoughts. I am hired to do the thinking around here. What's the matter with you? Can't you handle the job? If you can't, I'll damned soon put some one there who can. Get the h—— out of here now and get back into the round house and see that those men keep busy. If I catch any of them loafing on the job, I'll send you 'down the track talking to yourself'."

I needed that job. I realized that if I got fired my clearance would show lack of ability which would make it hard for me to get another chance. I went back into the round house determined to show the master mechanic, that if he wanted the job run the way it had been running, by hard-boiled, driving tactics, I was the man who could do it.

I must have succeeded after a fashion, for I was not fired. On the contrary, I gained the reputation of a hard, driving taskmaster, who would stand for no fooling. Later I was promoted to a somewhat more responsible position, so I was forced to the conclusion that my methods, if not of the best, were at least in accord with the popular ideas at that time.

I have never succeeded in building myself up to a real position in the railroad world, and as the years have passed I have more and more come to the conclusion that my methods have not been of the best. Regardless of the fact that I was driven by force of circumstances into a hard-boiled attitude of mind, I have always had a subconscious feeling that better work and more work can be gotten out of men by leading them than by driving. I have therefore welcomed the newer and better methods and have adapted myself to the present disposition on the part of the officials to exemplify the square deal in all relations with their employees.

I have gone into my personal affairs at length with but one object in view, and that is to point out the fact that if a foreman is hard-boiled, there may be an underlying reason for his mental attitude.

We will not be able to remedy conditions by painting beautiful word pictures typifying some super-foreman who possesses all the virtues and none of the faults of the rest of us poor mortals. If any of our foremen are hard-boiled, would it not pay to find out what their real or fancied reasons are for having that kind of a mental slant?

Inspiration must come from above

Why should it be necessary to preach the value of co-operative effort, education and the square deal to the foremen? Inspiration must necessarily come from above. Is it any less reasonable to think that the foremen would respond less quickly to such suggestions coming from their superiors, as they now expect the men to react to the teaching of the foremen?

Does not the very fact of the seeming necessity for such pronouncements to the foremen at this time constitute a serious indictment on the policies of their superiors in the past, and to some extent in the present? The foremen can go just as far and no farther than the stated policy of their company will allow. Like master, like man.

There are few foremen today who have not a full realization of all the advantages to be gained by following the policies set forth in the article by "Bill Brown." They don't need to be told those things. What they want is an opportunity to put them into effect.

They realize more fully, perhaps, than is generally suspected, that the first and greatest essential to success is a steady inflow of new knowledge that will better equip them in coping with their jobs. Very few of them get a chance to attend the conventions, and still less get an opportunity to travel around to observe the new methods in other shops, but all of them have an opportunity to subscribe to the technical magazines, and most of them do, Mr. Editor, or have done so at different times, until they have been satisfied that their efforts were futile. Personally I have received a great deal of good from reading the technical journals, but have seldom been allowed to put into use the many good ideas I have so acquired, on account of bumping into the "bogie" called "company standards."

What do they mean by company standards? Are they intended to be as unchangeable as the laws of the Medes and the Persians? Or should they be sufficiently elastic to permit of changing, if the occasion justifies? Should the foreman be instructed that these standards are inviolable, or should they be encouraged to figure out newer and better methods, with the understanding that they will be given credit if the changes are found acceptable?

Educational work must be directed

What effort is being made by the management of the different railroads to allow the foremen to present their side of the case? Are they encouraged to present their ideas in staff meetings or in articles? Is any effort being made to supervise and co-ordinate their reading to any practical end? Listen, Mr. Editor, let me give you an illustration of my meaning.

The field representative of your own paper, the *Railway Mechanical Engineer,* recently visited the shop where I work. He secured a subscription from every man of supervisory rank in the shop, as well as from a number of leading mechanics. He also sold a number of technical books. Before he left every man was provided with his text-books and had signified his willingness to study in order to be better equipped for his work. What was the result? No one to direct, supervise or co-ordinate their studies. No one to encourage them in applying the knowledge they may have secured, and no one of sufficient authority to permit of any changes of practice that might have been possible as the result of any knowledge so acquired. I don't believe your field man will have such good success here next year.

The railroads spend a lot of money each year in their safety campaigns. Good! It saves lots of lives and mutilated people as well as money for damage suits. They save lots of money by conserving coal, as the result of their fuel meetings. Why not spend a little money on an educational department that will direct and encourage the study that the foremen have signified their willingness to do, by virtue of having bought the necessary books?

Why not stop preaching at the foremen and co-operate with them in doing the things that they know, as well as you, are necessary to be done in order to ensure success?

JOE BUSH.

The foreman and his responsibility*

Emphasizes necessity for studying human nature and placing men where they can function to best advantage

By Zed E. Day

Gang foreman, C. C. C. & St. L., Beech Grove, Ind.

THE foreman has often been referred to as the "keystone in the arch of industry," and truthfully so, for as the keystone supports the arch of stone or brick, so does the foreman support and advance industry. His influence in this strategic point is felt by every individual connected with his organization, from the lowliest sweeper to the highest director. Since the foreman is such a vital part of the organization, it is well that he should take an inventory of his position and of himself and to come on speaking terms with his responsibilities and opportunities. The foreman is the one point of contact between the management and the worker; he acts as a representative for each. The manner in which he interprets the wishes of the management to his men forms the basis on which the men judge the management. Likewise the management will usually judge the workers by the way in which their problems and grievances are presented to them by the foreman.

It is within the foreman's power to make or break any rule, method, or process that it is desired to install, by the way in which he presents it to his organization. To the degree that he is for or against a proposition will it succeed or fail.

He is the one who organizes the workers—placing the right man on the right job; studying their characteristics; observing their strong points and their weak ones; helping them to overcome their weaknesses and to become of more value to the company. He is the one who knows and sympathizes with their problems, and instructs them in the

* One of the articles contributed to the competition on this subject.

most efficient manner of doing things. He is the one who arouses their interests to do greater and better things.

The foreman's principal job

His principal job is not, as a good many think, a matter of materials and machinery, but rather human nature. His chief responsibility is to study and know human nature, not only of his men, but also his own personality, so he will be enabled at all times to have proper control over the most essential element in industry—the human element—and at the same time have control of himself. Handling human nature is a battle and only fighters can win out in it.

Andrew Carnegie is reported to have said: "If I had to choose between losing my plants and equipment, or my organization, I would choose the former." Plants could be rebuilt and equipment furnished in a short time, but it would be the work of years to build another organization.

Since one of a foreman's main responsibilities is to organize his department, he should have a thorough understanding of the principles of organization. He must see that each man has certain duties for which he is held responsible, and that the man understands his duties and can carry them with a minimum of supervision. He must organize so that each little detail of his work is given to someone to perform regularly. He must learn to master detail—then learn to get rid of it. Too many responsibilities will break a man. The more details that can be taken care of successfully by others in an organization, the more time a foreman will have to do constructive work in improving methods and design. His advance in industry depends largely upon his organizing ability. This phase of his duties also presents a golden opportunity for mental development; he can experiment with men, the most intricate machine, by changing their duties occasionally, shifting them from one line of responsibility to another to ascertain their likes and dislikes, and to fit them in the right place. In doing this and observing his men he has the chance to learn the best way to organize, and will soon have a nearly perfect organization under his control. Great railroads, factories, steamships, telephone systems, and many other instances might be cited which are living monuments to organized forces intelligently directed.

Starting a new man

While the desire to produce more efficiently, and to eliminate waste is a paramount issue, it should not overshadow the need of training and the welfare of the worker. New men should be tactfully and judiciously dealt with, as their first impressions of a plant are likely to be lasting ones. Have a constructive talk with a new man to find out his aims and ideals, and inform him of the aims and purposes of the company, the quality of work expected; the location of the various departments; the natural progress of the product, and a general fund of good knowledge to give him his bearings on the job; an explanation of his assigned duties and their relation to the finished product. Finally invite him to feel free to ask any questions on anything he does not understand pertaining to his new work, and to make any suggestions for improvements in the plant that may occur to him. This policy will greatly reduce a tremendous waste due to labor turnover—a great problem in industry today.

The quality of the finished product is a responsibility which rests almost entirely with the foreman. He should familiarize himself with the quality of work expected and then produce nothing but work of that standard.

To the foreman who has vision enough to grasp these principles and apply them, I say his opportunities are unlimited. They will result not only in his advancement in industry, but also will he receive a great moral satisfaction which can result only in happiness and contentment in his work and in his life. This too, will make him worthy of his title, "The Keystone in the Arch of Industry."

Canadian National builds nine motor rail cars

Includes seven 60-ft. and two of articulated construction—Equipped with Diesel engines of light weight per horsepower

A NEW development in motor rail car design has been introduced by the Canadian National in the construction of nine Diesel-electric cars that are now being built at its Point St. Charles shops, Montreal, Que. Seven of the nine units are single cars having an overall length of 60 ft. and the remaining two are of the articulated type with an overall length of 102 ft. Including the articulated construction of two of the cars, the principal features in the design are the four-cycle Diesel engines and the use of three-passenger seats to obtain maximum seating capacity.

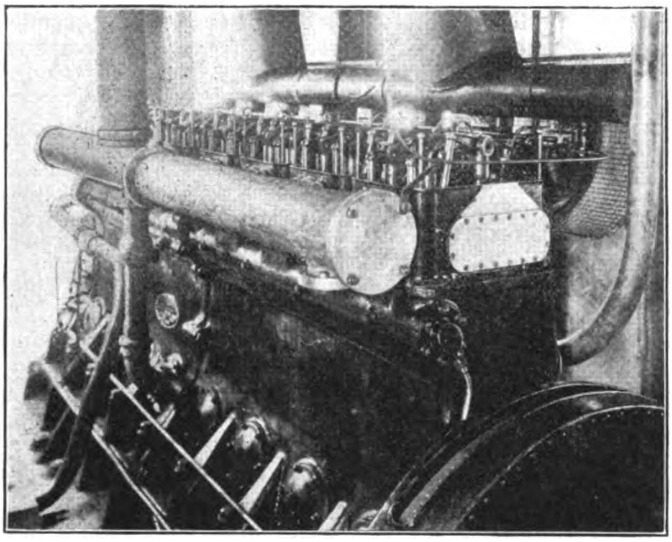
The engines

The engines installed in these cars were manufactured by William Beardmore & Co., Ltd., London, England. The design is a modification of this company's standard aeroplane engine which was changed to meet the service conditions of rail car operation. These engines conform to a modified Diesel cycle of the solid injection four-stroke cycle type and are arranged with four cylinders in line for the small unit which is used on the 60-ft. car, and eight in line for the large unit which is used on the articulated car. The cylinders in both engines have 8¼ in. bore by 12 in. stroke and develop 185 b. hp. at 700 r.p.m. in the small unit and 340 b. hp. at 650 r.p.m. in the large unit. The engine in the 60-ft. car weighs 2,750 lb. and that in the articulated car weighs 5,450 lb., or a fraction under 15 lb. per horsepower for the smaller engine and slightly more than 16 lb. per horsepower for the larger engine.

The low weight per horsepower was obtained through the selection of materials. The designers were able to reduce the thickness of the materials to a minimum through the use of high tensile steels and special alloys. For example, the crank case is of cast steel; the cylinder liners are made of forged steel; the cylinder heads, of

cast aluminum; the valve seats, of alloy steel; the pistons, of forged aluminum; the crank shaft of special forged alloy steel; the sump cover, of sheet steel; and the connecting rods, of special forged steel.

A feature in the design of these engines is the steel monobloc crank case, the upper part of which is bored out to receive steel liners, and thus form the water jacket around the liners. The main crank case casting carries the crank shaft bearings and also the base supports for bolting the engine to the underframe of the car. Large inspection doors are provided which give access to both end bearings. The lower part of the crank case consists of a light tray with an oil sump which is secured to the underside of the main casting. The main bearings are equipped with phosphor-bronze bearings lined with babbitt metal and are lubricated by a continuous oil pressure system. The connecting rods are made from special steel forgings, the top end bearing of which has a solid phosphor-bronze bushing, while the end is fitted with a pair of phosphor-bronze bushings lined with babbitt metal and fitted with an adjustable liner. Both bearings of the connecting rod are arranged for pressure lubrication.



The Diesel engine installed in the articulated car—It is of light construction, weighing slightly more than 16 lb. per horsepower

The pistons are made from forgings of a special aluminum alloy and are machined all over and balanced before finishing. Each piston carries four cast iron piston rings in addition to a scraper ring. The steel liners which are pressed into the main crank casing are also of light construction. The cylinder heads are made of an aluminum alloy and are provided with large spaces for the circulation of cooling water. Each cylinder head carries two exhausts, two valves and a central automatic spray valve as well as a compression release valve. The exhaust from each cylinder enters a manifold on the side of the engine for which one exhaust pipe for every four cylinders is carried vertically up through the roof.

The main crank case is a light steel casting and carries the housings for the ball bearings on which the gear wheel spindles run. Attached to the main gear case are the duplex lubricating oil filters, the oil pump and the centrifugal type cooling water pump, which is also equipped with filters.

Separate fuel pumps which deliver the fuel to the atomizers at from 8,000 lb. to 10,000 lb. per sq. in., are employed for each cylinder. A primary pump maintains an oil pressure on the suction side of the main fuel pumps. The injection is timed and the engine output is controlled by varying the effective piston delivery stroke. Any excess oil is delivered back to the fuel tank through a by-pass gear. A light residue oil of .86 specific gravity is used for fuel.

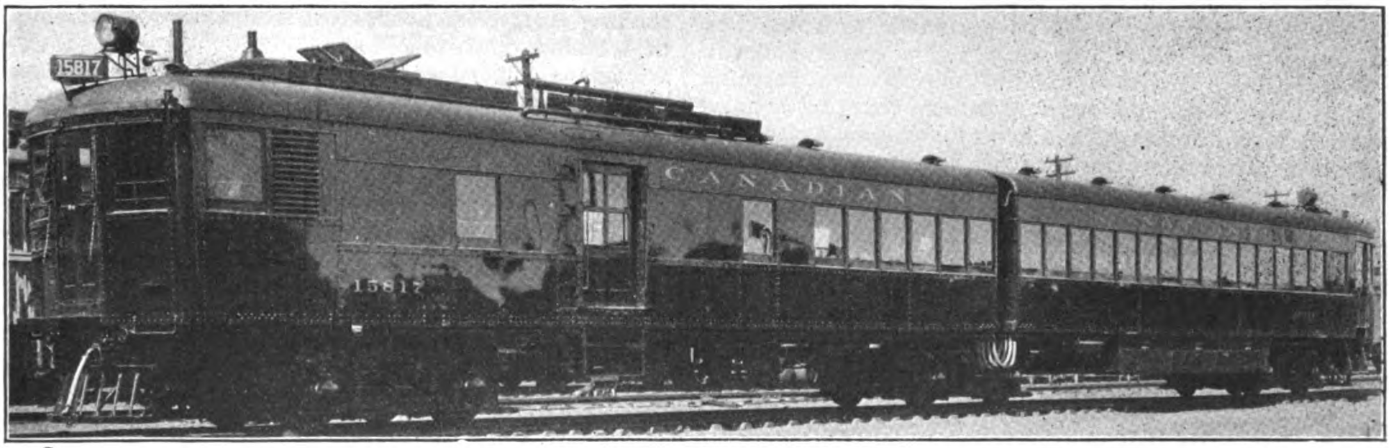
Engine auxiliaries

A centrifugal type governor driven off the crank shaft is coupled to the fuel pump control and is so arranged as to increase or decrease the oil supply to the fuel distributing system. It is fitted with an emergency device to cut the fuel pumps out of action should the r.p.m. of the engine for any reason be increased above the desired speed.

A centrifugal pump is used to circulate cooling water through the engine. This pump is mounted on the main gear case and can be easily detached for examination. Flow indicators are installed in the lubricating oil and cooling water circuits which indicate a stoppage of flow by lighting a lamp in the operator's room.

The tanks for water, fuel oil and lubricating oil are all made of 3/16-in. and ¼-in. aluminum plate and are located in the engine room. The piping is of aluminum, except in a few places where copper is used. The water tank on the 60-ft. car has a capacity of 120 gal.; the fuel oil tank, 75 gal., and the lubricating oil tank, 50 gal. On the articulated car the water tank has a capacity of 240 gal.; the fuel oil tank, 150 gal., and the lubricating oil tank, 100 gal.

Midwest air filters are applied to all of the cars for



Canadian National articulated Diesel-electric motor rail car

filtering the air supply to the engines. The filters used on the 60-ft. car are mounted on the ceiling of the engine room, while those on the articulated car are mounted on the left-hand wall of the engine room which is provided with shutter inlet to keep out the rain or snow.

The 60-ft. car has two full-size Rome Turney radiators mounted on the roof for cooling water and one half-size for cooling lubricating oil. The articulated car has four full-size radiators for cooling water and one full-size radiator for cooling lubricating oil.

The lubricating oil is forced under pressure to all working parts, including those of the cam shaft. Oil is drawn from the well in the sump, located at the gear case end of the engine, and is then forced through double filters via the cooler on the roof to the main supply tank. These filters can be cut out and cleaned while the engine is running. The oil then flows by gravity from the tank through a second pair of filters to the compressor pump which forces it through the crank shaft to the journals and pins and thence to the small ends at about 60 lb. pressure. A connection also leads to the cam shaft and oil is forced up through the center of the cam shaft to the bearings. Provision has been made to drain the unused oil in the engine back to the sump well.

The electrical equipment

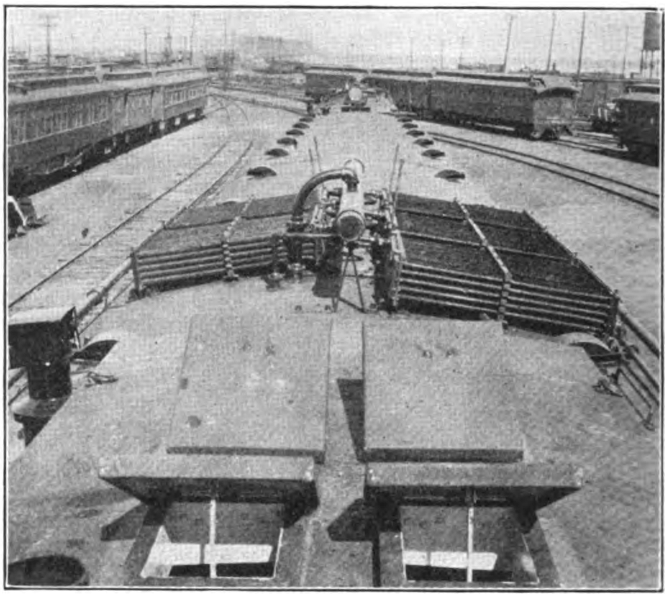
The electrical equipment on the articulated car was manufactured by the Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa., and consists of a 200-kw., 600-volt d.c. generator mounted on a common bed plate with the engine and connected to it by a Fast flexible coupling. Pressed felt liners 1½ in. thick are placed between the bed plate and the car sills to absorb vibration.

The generator is differentially compound wound, the shunt field being excited from a 300-volt battery. The motors are 600-volt railway type 548-C-8, with a one-hour rating of 145 amp. connected permanently in parallel and mounted two on each of the front and rear trucks and connected to the axles by helical gearing.

The car is operated by master controllers located at each end, different speeds being obtained by a resistance control of the main generator field. Besides the master controllers, the main control apparatus consists of a switch group comprising eight electro-pneumatic switches, two reversers, an overload trip relay, and a sequence drum. The auxiliary control apparatus consists of a potential relay, an ampere hour meter, a battery charging relay, a field relay, a throttle valve, a control and reset switch and the necessary knife blade switches for the control of the several circuits. False operation of the various circuits is prevented by necessary interlocking between controls, which also makes the operation practically automatic.

The air for the magnet valves is taken from the air brake system and is maintained at about 70 lb. pressure, the electro-pneumatic control being the standard H.L. equipment throughout. The acceleration of the car is practically automatic as the control can be thrown to the "full" position, allowing the sequence drum to increase the generator voltage in four or five seconds. All controller positions are, of course, running positions, and lower speeds than the maximum can be obtained by intermediate points on the controller.

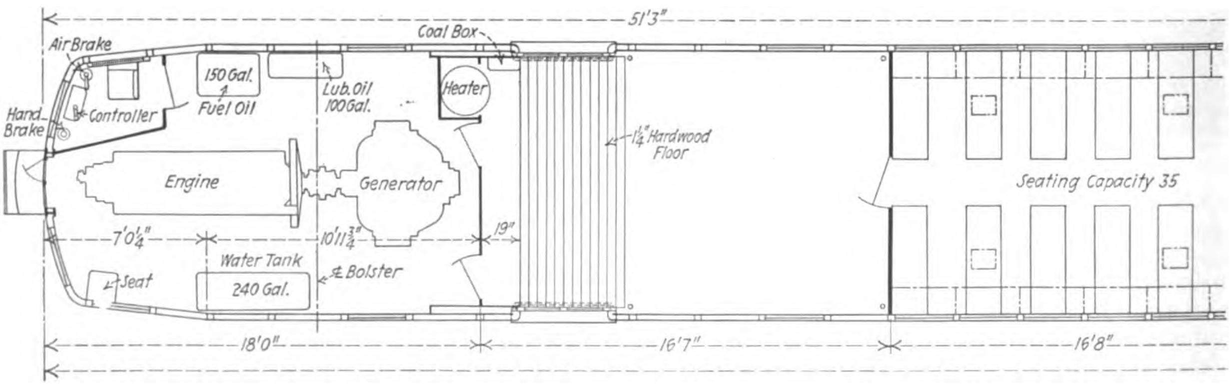
The engine is started by the generator driven as a motor, from the 300-volt battery, this starting position being obtained from the controller by moving the operat-



Top view of the articulated cars showing the radiators for cooling the oil and water

ing handle contrary to its operating direction. The engine starting position is also the battery charging position when the car is standing. By motoring the generator the 300-volt battery brings the engine to a speed of about 200 r.p.m. at which speed it fires on the first compression, the starting current for about two seconds being a maximum of 480 amp. down to 230 amp. at 150 volts. The battery voltage is applied to the generator through resistance steps and at the same time the engine throttle is moved by an electrically controlled air cylinder to full fuel position.

The battery is composed of 150 cells, M.V.A. 17 Exide Ironclad, and is located in two sections in steel boxes suspended from the floor of the rear half of the car. With the car running and the controller on either of the last



Floor plan of the articulated motor rail cars

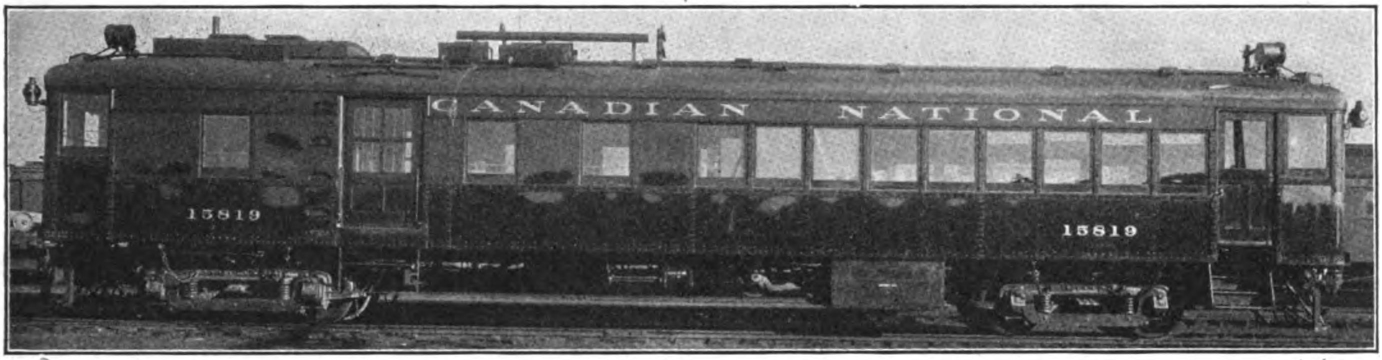
two notches, the potential relay cuts in and allows the generator current to charge the battery. This continues as long as the controller is on either of the last two notches or until the charging current is cut off by the ampere-hour meter.

Besides being used for starting purposes, the battery also supplies the control circuits at 30 volts; the generator field excitation at 300 volts; the two air compressors at 300 volts, and the car lighting at 30 volts. Low voltage circuits can be distributed over 90 of the 150 cells and standard lamp regulators are used to compensate for the charging voltage. Emergency switching is provided so that any of the 30-volt sections can be charged from the generator while the car is standing. One of the main reasons for having the 300-volt battery is that in case of necessity, owing to a total engine failure, the car can be moved on half voltage to the next siding, in order to clear the main line.

In carrying the circuits across the articulation, every effort has been made to secure accessibility and reliability. All the control wires are carried through the ceilings of the cars, terminating at each side of the articulation in junction boxes located in the car ceiling. The only heavy cables crossing the articulation are the generator bus liners to the motors, the battery line to the generator and the train line lighting circuit. By locating a reverser on each half of the car, the necessity of carrying the motor leads across the articulation is avoided. Multiple unit control has been installed so that two or more cars can be operated from any one operator's position.

The electrical equipment of the 60-ft. car was manufactured by the British Thomson-Houston Company, Rugby, England and the General Electric Company, Schenectady, N. Y. The generator, which was shipped with the engine from England, is a 105-kw., 600-volt d.c. differentially compound wound machine mounted on a common bed plate with and rigidly connected to the engine. Pressed felt liners 1½-in. thick are placed between the car sills to absorb vibration. On the same shaft with the generator is mounted a 6-kw. 60-volt exciter. The balance of the electrical equipment consists of two G.E. 240-A, 600-volt, 150-amp. (one hour rating) railway motors, mounted on the front truck and connected through helical gears. The controllers located at each end connect the motors in series, parallel or shunt field forward, and series or parallel reverse.

A 120-volt M.V.A. 17 Ironclad Exide battery is carried underneath the rear of the car. Thirty cells are suspended from the floor in a steel battery box on each side of the car. This battery furnishes starting current for driving the generator as a motor in a manner similar to that described for the articulated car, only 16 cells of which, however, supply the excitation of the exciter field and the car lighting. The 120-volt battery is charged from the generator by a special charging circuit used while the car is standing. The 32-volt portion is automatically charged by the exciter when its voltage is higher than the battery voltage.

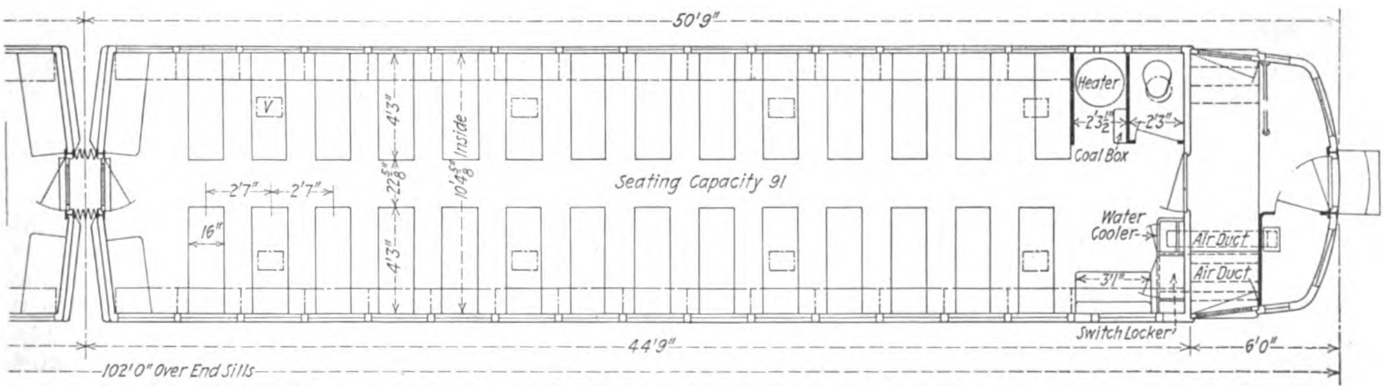


One of the seven 60-ft. Diesel-electric motor rail cars being built by the Canadian National

The car speed is controlled by the engine throttle, which is mechanically connected to an operating lever located in the operator's cab at each end of the car. The electrical controllers merely connect the motors to the generator circuit in series or parallel and are not used to operate the car. The first movement of the throttle lever closes the throttle relay switch, thus closing the exciter field circuit, and allowing the generator voltage to build up from zero across the driving motors. A further opening of the engine throttle increases the generator voltage and, therefore, the car speed.

Interiors of both types of cars are of similar design

The two types of cars contain many similar features of design and construction. The bodies of both the 60-ft. and the articulated cars were built by the Ottawa Car Manufacturing Company and are of steel construction throughout. The interiors are finished in mahogany and



recently placed in service by the Canadian National

have a 5/16-in. Agasote ceiling painted in cream color. Double floors are applied throughout with the exception of the engine rooms where a single floor 1¼ in. thick, covered with checkered aluminum floor plates, is used. The floor consists of one layer of 13/16-in. white pine and a top floor of ⅝-in. fir, with a double thickness of building paper between. The side lining below the windows is 5/16-in. Agasote painted to match the interior finish. Both types of cars are equipped with single windows of cherry, to which storm sash can be applied for winter use. Three-ply Salamander insulation is applied below the windows, two-ply above the windows and one-ply on the ceiling. The roof boards are of ½-in.

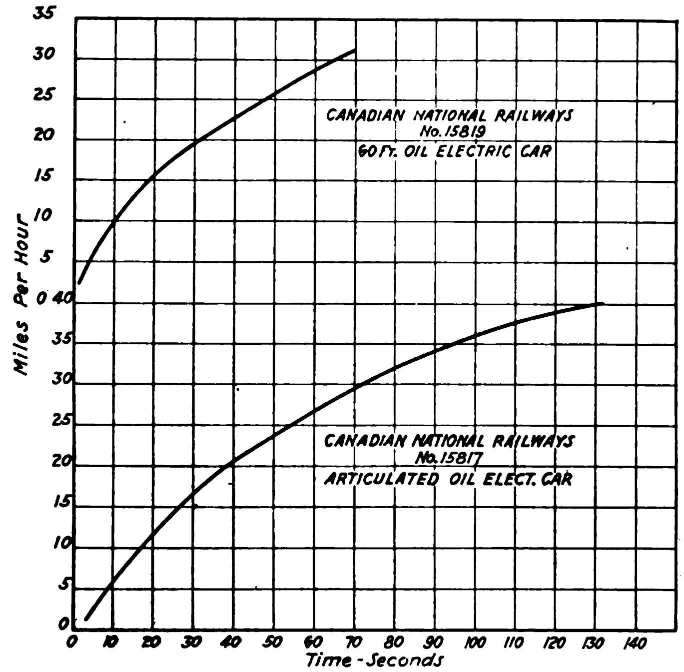


Chart showing acceleration curves for the 60-ft. and articulated cars on level track

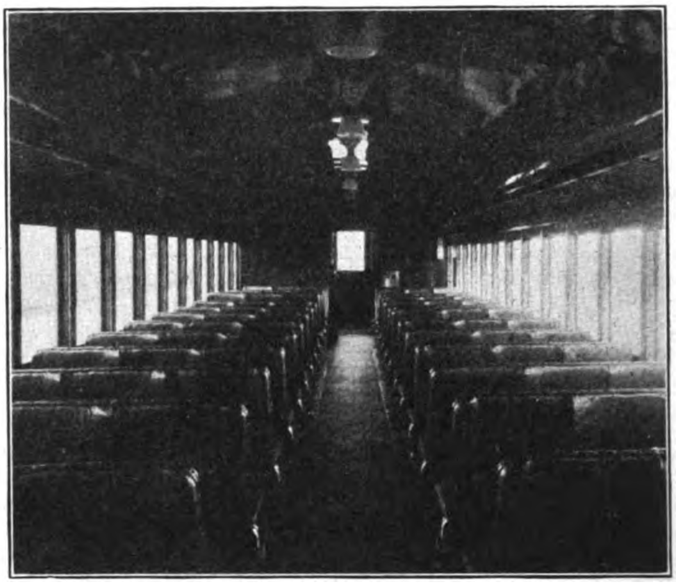
whitewood covered with No. 6 canvas laid in white lead. Parcel racks running the full length of the passenger compartments are provided.

Electric lighting is provided from 30-volt storage batteries. Aluminum conduits for carrying the lighting circuits, power and control circuits are used throughout.

The articulated car has three-passenger seats

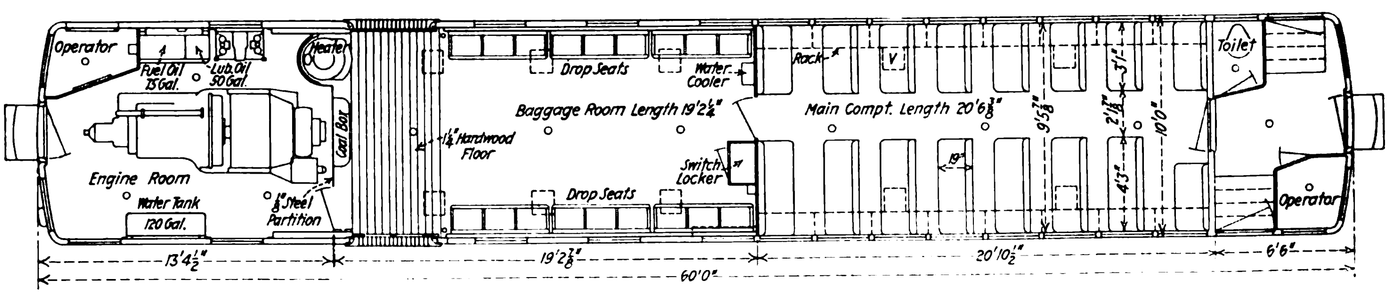
Each unit of the articulated cars consists of two bodies mounted on three four-wheel trucks. As shown in the floor plan of the articulated car, the front half contains the engine room, baggage room and smoking compartment which has a seating capacity of 35 persons. The



Interior view of the rear unit of the articulated car—The seats are designed for three passengers

rear half has a seating capacity of 91. The seats used in both compartments are of the Heywood-Wakefield reversible type, placed 2 ft. 7 in. center to center, and are upholstered in Spanish leather. Forty of the seats each accommodate three people while three seats provide for two passengers each, giving a total seating capacity for the articulated car of 126. The inside width is 10 ft. 4⅝ in. which permits the installation of seats 4 ft. 3 in. wide and allows an aisle space of 1 ft. 10⅝ in.

The length over the end sills of the front half of the articulated car is 51 ft. 3 in., and the length over the end sills of the rear half is 50 ft. 9 in. The overall height is 14 ft. 4⅜ in., and the width over the side sills is 10 ft. 10¾ in. The inside length of the engine room of the articulated car is 17 ft. 6 in., and the inside length of the baggage compartment is 16 ft. 6 in. The partitions



Floor plan of the 60-ft. motor rail car

Ventilation is provided by exhaust type ventilators in the roof. Smith hot water heaters are used for heating both types of cars. The 60-ft. car is equipped with one hot water heater which is placed in the baggage room. The articulated car has a heater located in the baggage room and one at the rear end of the passenger compartment. All of the pipes used in the heating system are of aluminum.

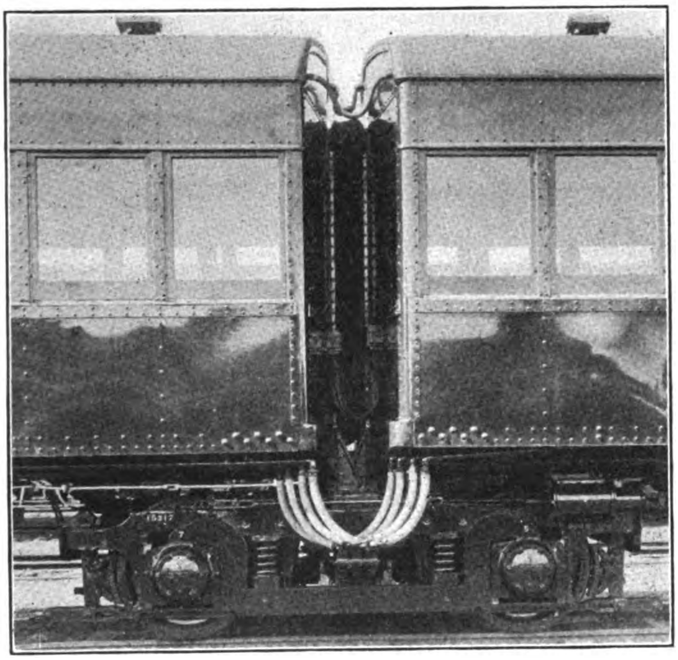
between the engine room and baggage room are of steel and are so constructed that they can be removed if necessary to work at the power unit. Roof hatches are provided directly over the engine and generator so that either may be removed by a crane for repair purposes. The hatch covers are provided with four ventilators operated from the engine room.

The three trucks of the articulated car are of Com-

monwealth design having 5-in. by 9-in. journals and 36-in. rolled steel wheels. The journals are equipped with S.K.F. self-alining roller bearings. Motors are mounted on the front and rear trucks only.

The center truck of the articulated car carries one end of both the front and rear body sections. Each section is provided with a special cast steel end sill to which are bolted center castings, one of which sets within the other, both engaging the truck center plate. A safety type locking pin is used, and safety bars are also provided. A one-piece canvas diaphragm encloses the space between the front and rear halves and a diamond steel foot plate is located at about the floor level.

The brake equipment is Westinghouse, schedule A.M.F. The air pressure on the articulated car is supplied by two DH-16 compressors connected in parallel. The braking ratios are based on 50-lb. cylinder pressure, being 83 per cent on the front and rear trucks and 75 per cent on the center truck. The trucks are equipped with the A.S.F. suburban type Simplex clasp brakes. The front and center trucks are fitted with a new design of brake which consists of a standard Type D freight brake cylinder mounted on each side of the truck frame and connected



Exterior view showing the center truck and connections between the two units of the articulated car

directly to the front brake gear. A flexible cylinder pipe connection is located near the center of the truck. On account of insufficient clearance, the cylinder for the rear truck is attached to the car body.

The sixty-foot car

The seats in the 60-ft. car are of the same design and manufacture as those of the articulated car. They accommodate three persons on one side and two on the other. In addition, the baggage room of this car is provided with drop seats of wooden construction giving a total seating capacity of 57.

The width over the side sills is 10 ft. which allows an inside width of 9 ft. 5⅞ in. The overall height is 15 ft. ¾ in. The distance between truck centers is 39 ft. 3 in. making a total wheel base length of 46 ft. 1 in.

Compressed air for the 60-ft. car is supplied by a General Electric CP28-D compressor. The braking ratio is 83 per cent based on 50-lb. cylinder pressure. The trucks are equipped with single shoe type brake with the standard body brake arrangements. They have 36-in. rolled steel wheels, A.R.A. boxes and brasses, cast steel side frames and built-up bolsters. The front truck carries two motors and has 5-in. by 9-in. journals. No motors are used on the rear truck which is equipped with 4¼-in. by 8-in. journals.

Both cars are equipped with the Universal Draft Gear Attachment Company's hand-brake booster and vertical operating ratchet handle. The standard train air communicating signal system is used.

A 12-in. Golden-Glow headlight is mounted on the roof at each end of each car. The Canadian National standard number lamps and Strombos horns are also provided, as shown in one of the illustrations. Miniere window cleaners are installed on the front window of each operator's room. Each car is equipped with a listening tube which runs from the engine room to the rear operating room. Sand boxes are suspended from the underframe and are filled through holes in the car floor. Hanlon sanders provide sand to the front of the front truck and to the rear of the rear truck.

Principal dimensions and proportions of the Canadian National Diesel-electric cars

Capacity of fuel tanks	75 gal.	150 gal.
Length over couplers	60 ft.	102 ft.
Width, inside	9 ft. 5⅞ in.	10 ft. 4⅝ in.
Height, overall	15 ft. ¾ in.	15 ft. 4⅜ in.
Diameter of wheels	36 in.	36 in.
Size of journals	5 in. by 9 in., front truck, 4½ in. by 8 in., rear truck	5 in. by 9 in.
Total seating capacity	57	126

It is reported that both cars have attained a speed on level track of approximately 60 miles per hour and show a low fuel consumption. Both cars have sufficient power to handle a trailer over an average profile at a proportionally reduced speed. Car accelerations up to 40 and 30 miles per hour respectively have been made in actual test.

THE FEDERAL DISTRICT COURT for eastern New York holds that under the Boiler Inspection Act each day of use of a locomotive with a defective boiler is a separate violation of the statute.—U. S. v. L. I., 4 Fed. (2d) 750.

THE AVERAGE COST OF COAL for road locomotives in freight and passenger train service (charged to operating expenses) in May was $2.73 a ton, as compared with $3.07 for May, 1924, and $2.80 for the first five months of 1925, according to the monthly statement compiled by the Interstate Commerce Commission. The cost of fuel oil per gallon, however, was 3.24 cents as compared with 2.86 cents last May and the total cost of coal and fuel oil for the month was $25,880,953, as compared with $28,014,369 last May. For the five months' period the total cost of coal and fuel oil was $138,683,648, as compared with $160,251,663 last year.

Diesel-electric locomotive built by Baldwin

The twelve-cylinder engine develops 1,000 horsepower—The rated maximum tractive force is 52,200 lb.

A DIESEL-ELECTRIC locomotive has been built by the Baldwin Locomotive Works, Philadelphia, Pa., which has the largest horsepower capacity of any internal combustion locomotive yet built in this country.

The rated maximum tractive force of the locomotive is 52,200 lb., the oil engine having a rated capacity of 1,000 hp. The total weight of the locomotive is 275,000 lb., of which 180,000 lb. is carried on the driving wheels. The total length over the couplers is 52 ft. 1¾ in. The locomotive has a total wheel base of 38 ft. 4 in. and a rigid wheel base of 12 ft. 8 in. The electric transmission consists of four Westinghouse type 353-D-3, standard railroad type, self-ventilating 200-hp. motors which are geared to the driving axles through flexible gearing. Power is furnished to these motors by a Westinghouse self-ventilating, direct current generator and exciter directly connected to the engine.

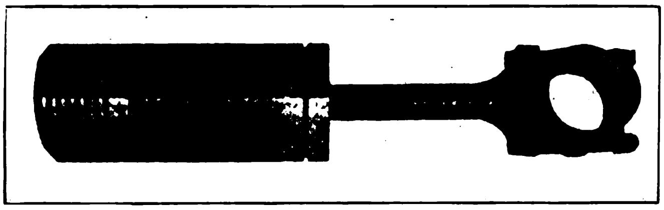
Referring to the illustration showing the side view of the locomotive, it will be noted that the general appearance is similar in many respects to that of an electric locomotive. The cab is of all-steel construction and extends the entire length of the frame. The height from the rail to the top of the cab is 14 ft. 7 in. and the width overall is 10 ft. 5 in.

The power plant of the locomotive is carried on two six-wheel trucks, each made up of the usual locomotive type bar frames in the pedestals of which are mounted outside journal boxes of three pairs of wheels. The two motors in each truck are geared to the outside axles, the middle pair of wheels running idle. The power plant, consisting of the oil engine, the direct-connected generator and the auxiliaries, is carried on two longitudinal cast steel girders which are connected by cast steel cross-ties at each end. These cross-ties also contain the center pins which engage the center plates of the two motor trucks. The drawbar pull is transmitted from one truck to the other through a drawbar and radial buffer construction at the inner ends of the two trucks, of a type commonly used in electric locomotive design.

A feature in the design of this locomotive is the arrangement of the spring rigging which has been patented by the builder. Two springs are placed over each box, one on the inside and one on the outside of the frame, each resting directly on top of the journal box and connected with each other by short cross equalizers at each fixed attachment to the frames. These equalizers allow for any variation in the height or deflection of the two springs which act together. Placing the spring alongside of, instead of over the top of the frame as would be required by the usual arrangement of one spring for each journal box, permits the lowering of the center of gravity of the locomotive at least six inches and also permits a corresponding increase in the headroom in the cab.

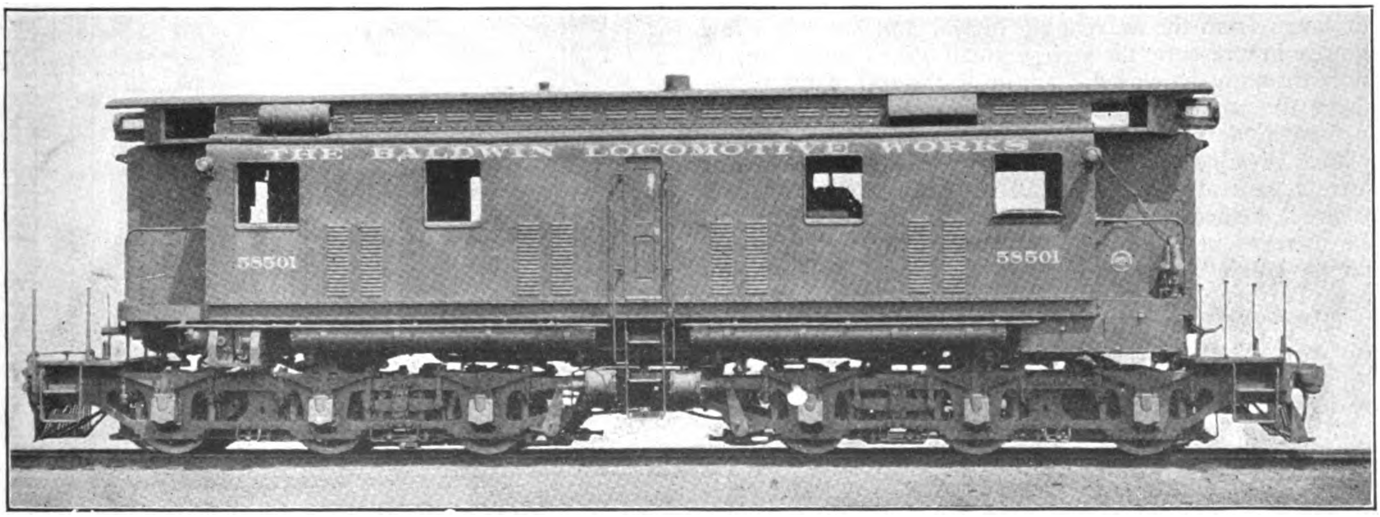
The Diesel engine

The oil engine, which is of the two-cycle solid injection type, was built entirely in the shops of the Baldwin



The head of each piston is provided with a long port to permit the entrance of air for cooling

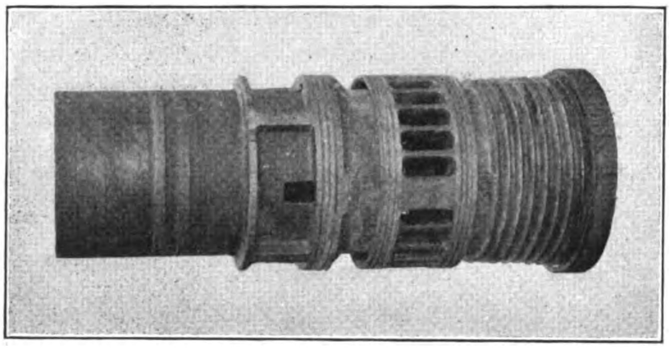
Lcomotive Works according to an arrangement with the Knudsen Motor Corporation, New York. There are twelve cylinders arranged in two groups of three pairs each, the pistons in the two cylinders of each pair driving on separate parallel crank shafts. Each pair of cylinders, however, has a common combustion space,



1,000-hp. Diesel-electric locomotive built by the Baldwin Locomotive Works

enclosed by a single head casting and supplied with fuel through a single injection nozzle. The six fuel pumps, one for each combustion chamber, are operated by a cam shaft. In the center of each of the two crank shafts, between the two groups of cylinders, is a large herring-bone gear, the gears from the two shafts meshing with a herring-bone pinion on the end of the generator shaft which steps up the crank shaft speed of 450 r.p.m. to 1,200 r.p.m. at the generator.

The cylinders, which have a diameter of 9¾ in. and a stroke of 13½ in., contain the ports usual in two-cycle internal combustion engines near the end of the stroke. The gears, which keep the two crank shafts in constant angular relationship, are so meshed that the pistons on one side of the engine are in slight angular advance in relation to those on the other side. Through the ports in these cylinders the exhaust takes place, to be followed by the admission of scavenging air from a manifold connected to the corresponding ports on the other side of the engine. The scavenging air thus enters through the ports in one cylinder and passes up through that cylinder, down through the other and out through the exhaust ports once in each revolution. On the return stroke the piston on the exhaust side of each pair of cylinders closes the exhaust ports slightly in advance of the closing of the air intake ports of the other cylinder so that scavenging air, which is delivered by a



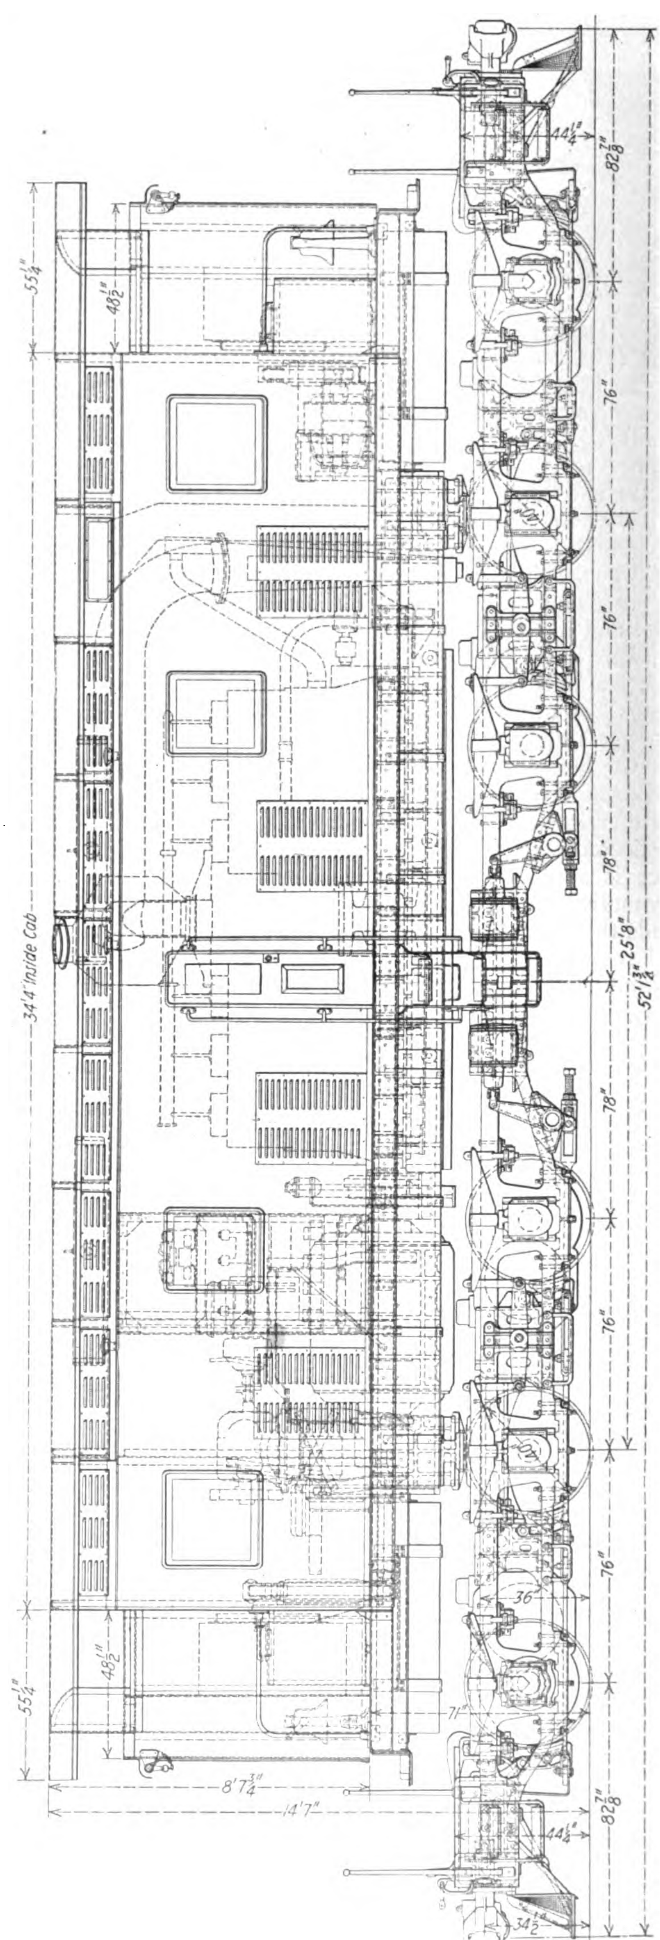
View of the cylinder showing the ports used for scavenging and for piston cooling air

blower at about 2½ lb. pressure, builds up to this pressure in the cylinders before the intake port closes and compression begins. In this way a degree of super-charging is effected which materially increases the amount of power that may be developed in a given cylinder volume.

Another special feature of the engine lies in the port openings in the cylinder and piston walls which permit air taken from the scavenging blower and boosted a few ounces in pressure through a small gear-driven fan, to blow through the closed chamber in the top of the piston above the wrist pin and mingle with the scavenging air in the cylinders, the purpose being to cool the pistons.

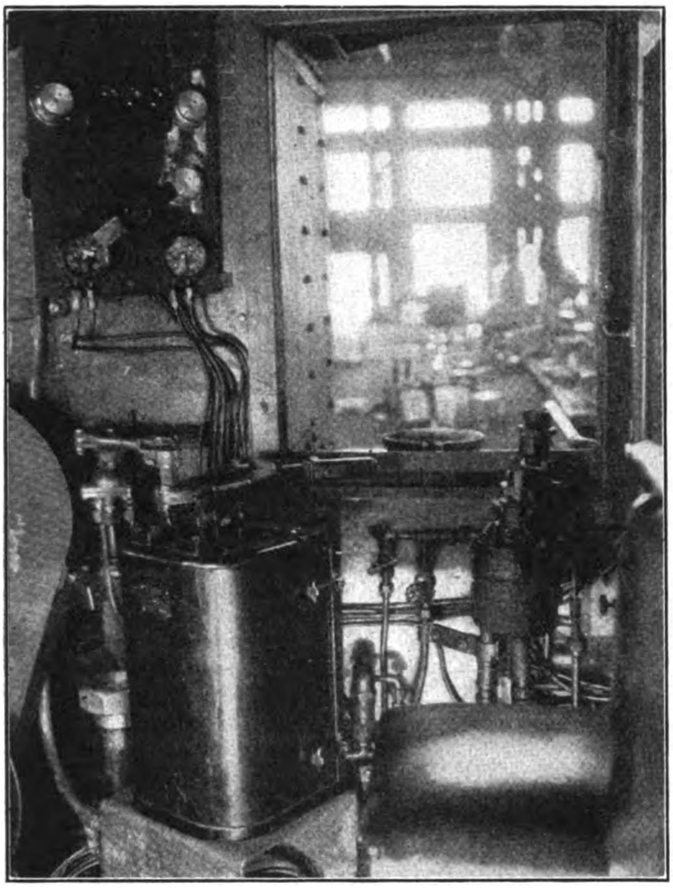
The Westinghouse 750-kw., separately excited, direct current generator develops 750 volts at 1,200 r.p.m., and is direct connected to the step-up shaft of the oil engine, the increase in the speed of this shaft over that of the engine crank shafts permitting a material reduction in the generator weight.

The principal auxiliaries which form a part of the power plant are the scavenging blower, the water cooling system and the air compressors. The scavenging air is delivered by a centrifugal blower which is driven at 3,600 r.p.m. by a gear connection to an extension of the generator shaft. This blower has a capacity of 4,500 cu. ft. of air per minute at 2½ lb. pressure. The water cooling system, which was designed by the Modine Manufacturing Company, Racine, Wis., consists of two radiators, one built into each end of the locomotive cab, the



Elevation of the Baldwin Diesel-electric locomotive showing the power plant in outline

water being circulated by a gear pump driven from the engine shaft. Air is circulated through each radiator by a fan, the fan at the front end of the locomotive being driven mechanically from the engine shaft, while that at the rear end opposite the generator is motor driven.



Interior view of the cab showing one of the control stations

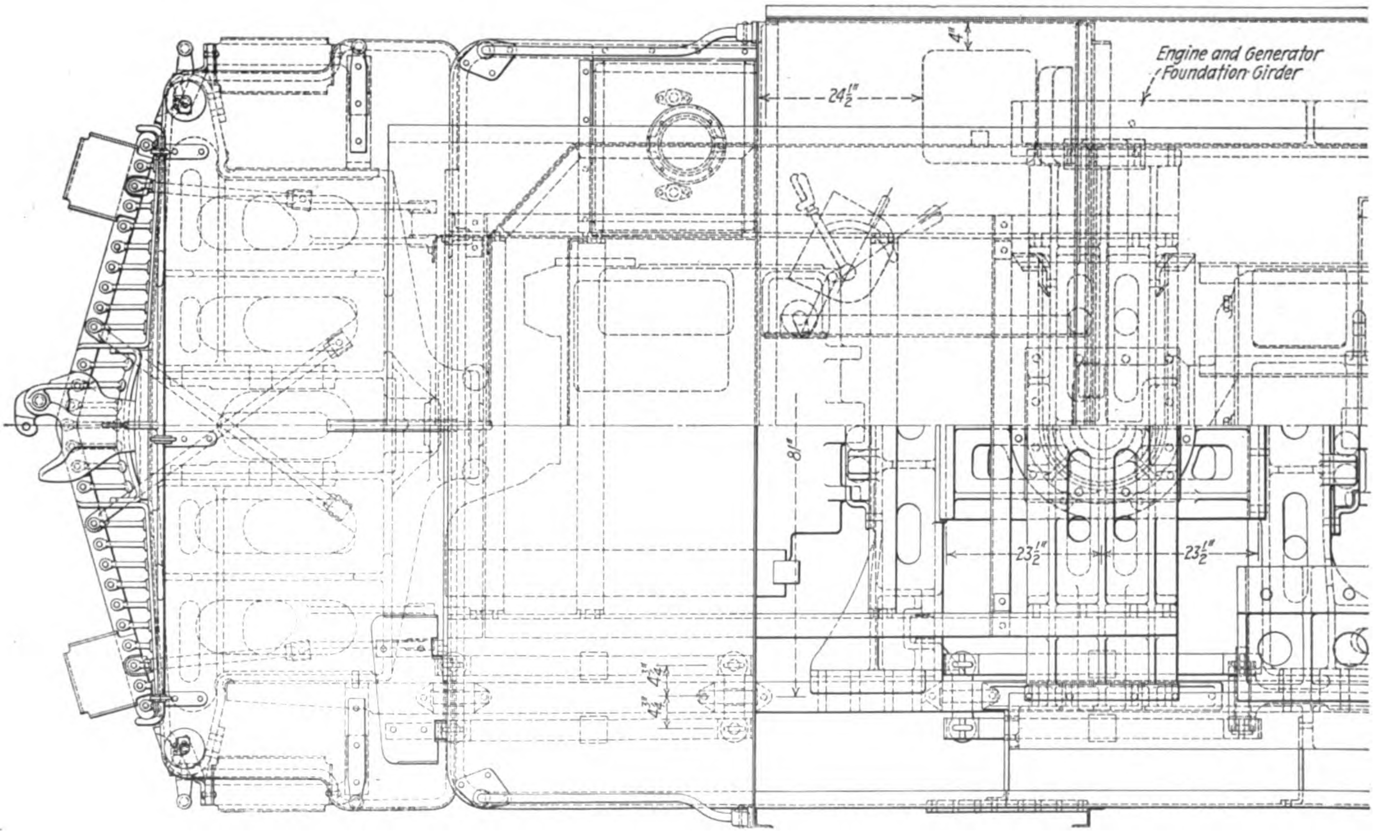
The locomotive is equipped with three Westinghouse motor-driven traction air compressors. One of these is suspended under the cab at each end of the locomotive, while the third is mounted in the cab over the generator. Connected by means of a clutch to an extension of the motor shaft of this compressor is a small four-cylinder gasoline engine which is used in starting the locomotive to build up a main reservoir pressure of about 120 lb. to supply air to turn over the Diesel engine the few revolutions required before combustion takes place in the cylinders. The gas engine is then declutched and stopped, the compressor continuing to operate as a motor-driven unit under the same automatic control as the other two units.

The starting system consists of six air distributing valves operated by the cam shaft, each admitting air to its pair of cylinders through a check valve in the cylinder head. A single throttle admits air to all the distributing valves when the motor is to be started.

The lubrication of the engine is a combination of the force feed and splash systems, the oil circulating pump being driven mechanically from the engine shaft.

The control equipment

The control equipment, which is of the Westinghouse electro-pneumatic type, is arranged for double end operation of the locomotive. With the Diesel engine and generator running at a constant speed, the locomotive is accelerated from standstill by the manipulation of a master controller, shown in one of the illustrations, by which the voltage of the generator is increased in steps, through field control, as the speed of the locomotive increases. With full generator voltage for a given generator speed developed in this way, further acceleration is effected by increasing the Diesel engine speed and, hence, the generator power output. The oil engine throttle is controlled by the manipulation of a valve handle on the master controller, which permits the increase or decrease of oil pressure in a cylinder, the piston of which, in moving out-



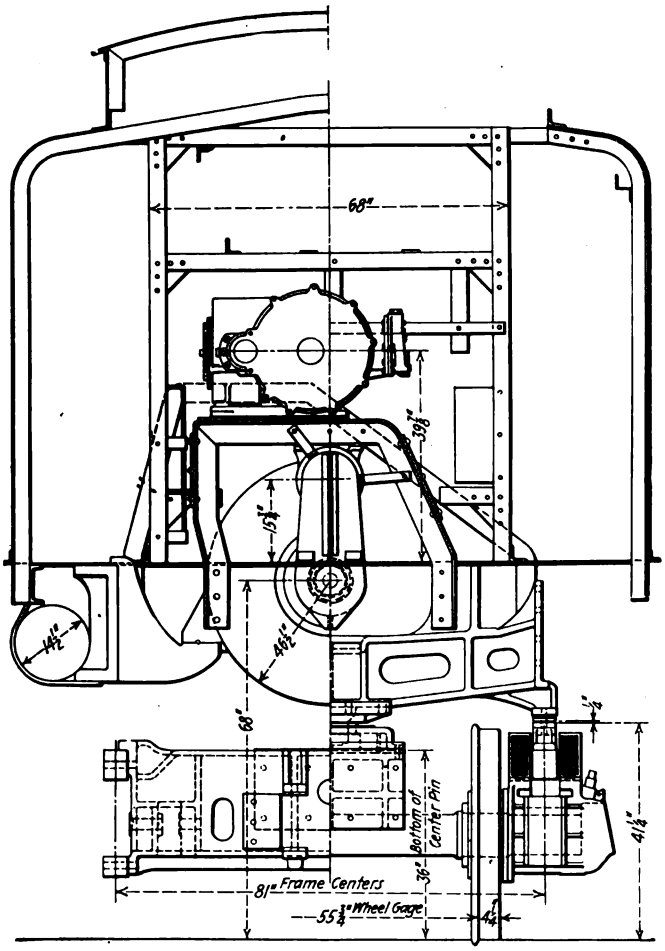
Partial plan of the locomotive showing the end construction of the power plant foundation

ward, compresses the governor springs. The throttle thus controls the speed at which the governor operates to reduce the stroke of the oil injection pump pistons. The unusual feature of this throttle control from the operator's standpoint, lies in the fact that it is manipulated to admit or release oil, supplied at constant pressure, to or from the control cylinder, only long enough to produce the desired engine speed, and is then brought to lap position until another change of power output is required.

Service trials

The locomotive, which was built in June, 1925, has for some time been in service on the Reading, part of the time in road freight service, between Reading, Pa., and Tamaqua, and part of the time in yard service. In both services the locomotive has given a good account of itself from a mechanical and power standpoint, the high tractive force characteristic of a constant power output machine adapting it particularly well to heavy switching service.

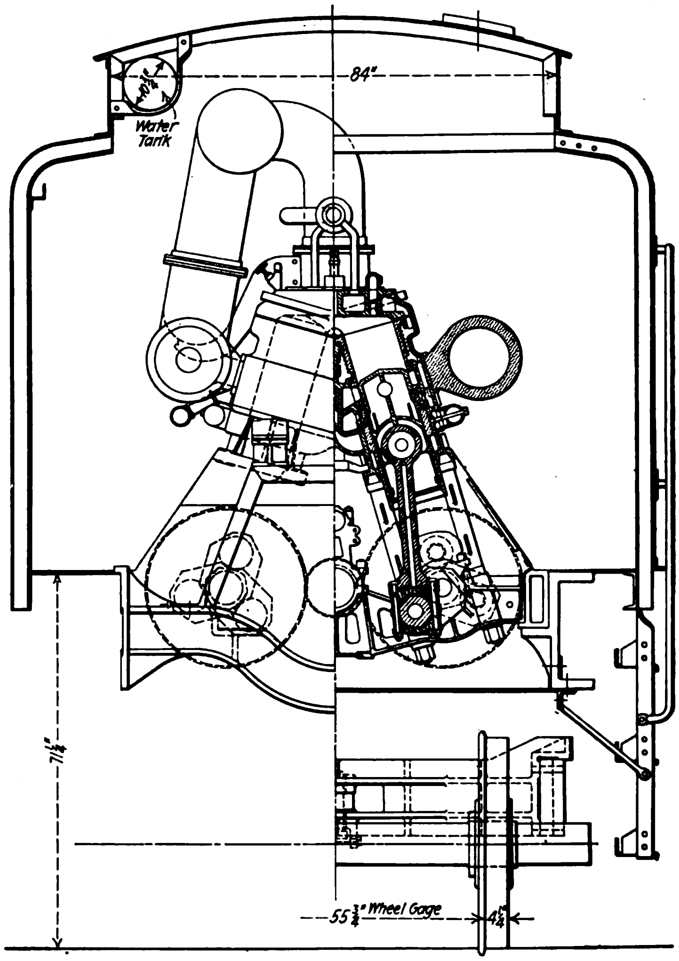
While no attempt has yet been made to test the loco-



Cross section at the generator end of the cab

motive accurately in actual service, the following operating results have been obtained. The locomotive has handled 1,000-ton trains from Reading to Tamaqua, a distance of approximately 40 miles, about three-quarters of which is upgrade at the rate of about .7 per cent with an average of 3.3 gal. of fuel oil per 1,000 gross ton-miles. It has moved these trains over the grade at a speed of approximately 16 miles an hour. On the runs in the reverse direction, with 2,000-ton trains, the fuel consumption averaged one gallon per 1,000 gross ton-miles.

The block tests of the engine indicate a fuel consumption of .40 lb. per horsepower hour at full load, increasing to .45 lb. per horsepower hour at half load. The



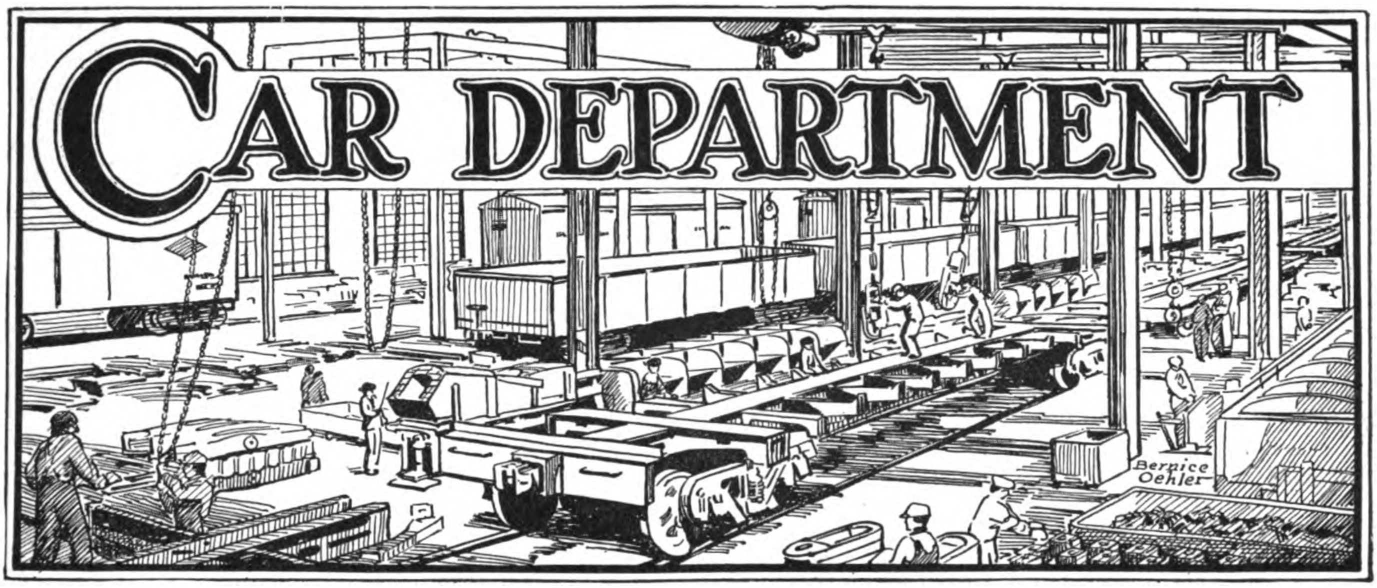
Cross section through the locomotive, showing a section through one of the oil-engine cylinders—the scavenging air manifold is shown at the left and a section through the exhaust manifold is shown at the right

engine has developed a maximum crank shaft speed of 480 r.p.m. It operates smoothly with very little vibration.

Principal dimensions and proportions of the Baldwin Diesel-electric locomotive

Builder	Baldwin Locomotive Works
Type	Diesel-electric
Weights on drivers	180,000 lb.
Total weight	275,000 lb.
Wheel bases:	
Truck	12 ft. 8 in.
Total locomotive	30 ft. 4 in.
Diesel engine:	
Type	Knudsen, 12 cyl., 2 cycle
Rated capacity	1,000 hp.
Cylinders, diameter and stroke	9¾ in. by 13½ in.
Generator:	
Type	Westinghouse, 750 kw. d.c.
Voltage	750
Motors:	
Number	4
Type	Westinghouse, Type 353-D-3, 200 hp.
Capacity of fuel tanks	750 gal.
Length over couplers	52 ft. 1¾ in.
Diameter of wheels	40 in.
Size of journals	7½ in. by 14 in.

The Bureau of Locomotive Inspection of the Interstate Commerce Commission in September inspected 6,556 locomotives, of which 2,835 were found defective and 302 were ordered out of service, according to the Interstate Commerce Commission's monthly report to the President on the condition of railroad equipment. The Bureau of Safety inspected 120,242 freight cars, of which 4,705 were found defective, and 2,175 passenger cars, of which 30 were found defective.



Testing paint by the removed film method

The presence of inferior bases and reducing oils can be easily determined—Tests of new stock prevent waste

ABSTRACTS of a number of papers presented at the fourth annual meeting of the Equipment Painting Section of the Mechanical Division, American Railway Association, held at St. Paul, Minn., the week of September 14, were published in the October issue of the *Railway Mechanical Engineer,* page 635. Following are abstracts of a paper and a committee report on the general subject of paint testing.

Is testing paint stock a useless innovation?

By W. O. Quest
Foreman painter, P. & L. E., McKees Rocks, Pa.

In all trade craft activities, new methods, ideas and materials are rapidly advancing. The paint craft is facing its share of an endless introduction of the by-product discoveries developed by alleged scientific research and doubtful authorities. Seemingly strange, bad and very bad paint stock threaten to keep the craft guessing and in order to feel safe, the future painter will possibly be compelled to study chemistry before claiming to know his business thoroughly.

This threatened future study of the chemistry of paint is also a vivid reminder of the activities of the late C. B. Dudley, chief chemist, Pennsylvania, Altoona, Pa., who decided that all new paint and varnish stock or formula should be tested through the medium of applied and removed films instead of by the separate raw material analysis before combining.

During the years of the writer's experience, oils, paints, varnishes, lacquers, liquid wax reducers, tars, etc., were removed and put on the "judgment drying line," with varied and surprising oxidizing results. Some of the best looking and working combinations when hung up would become brittle and fall off in a few days; others would soften up and, ribbon like, badly stretch down, showing other extremes of the freakish nature and action of the impracticably combined paint stock.

Until time made him wise to the unlimited deviltries of some paint offerings on the market, the writer was much exercised in finding formulas for paint that were soluble in water in the floating off process. In several such experiences, the water solubility action was so great that the removed film was almost reduced back to the liquid state. There were a number of instances where the watersoaked films turned white and failed to dry out normally as any pure paint stock should. As this phase of the trouble usually followed some claimed "world beating new stuff," he decided the cause to be a soapy over-oxidation of some water, sensitive over-emulsionized greases or other like matter, or through the use of some burnt-up precipitated kettle bottoms, called carbon waxes or gums susceptible to water contact. As this trouble was found repeatedly in film tests, it can readily be seen what would be sure to happen, and does happen, when such water permeating paint bases are weather exposed as a protective paint.

There were first class, honestly manufactured gum-bodied reducing oils that retained their elasticity through the removed film tests. There were also similar appearing oils and handling oils found to be absolutely worthless for any protective paint purpose. As an old-timer, the writer was pleased to find that for craft convenience, critical safety, etc., linseed oil would always show its presence; that the best substitutes were always linseed oil based; that in combinations, commercially pure, or in its most perfect refined "lin-oxylin form," it would show

up in the film tests with such gratifying results that he was thankful there was such a reliable, generally accepted material as linseed oil.

There seemingly is no limit to the fixed base substitute and reducing paint oil production. Some of the offerings were so gelatinous that they would liver up, waxlike, beyond the possibilities of further reducing out; others would drop their essential drying matter, slowing up the reducer of the sample. In the tests the substitute lower grade of oils would always throw off more volatile matter.

The principal substitutes filmed were selected as known to be generally used in combination or as straight substitutes for linseed. In order to be fair, the filmed base substituted oils were all used raw and ground in the same grade of pigment and also the proportion of special japan or other reducing matter.

Bodied-up cotton, corn, peanut, rape, parrilla, fixed pine and several mystery oils were pigment based and filmed. The parrilla made the best body showing but was hard to handle, notwithstanding that it is claimed to be linseed's nearest rival, and possibly is, if skillfully handled.

Mineral oils, in the film tests, were a source of many hard efforts and disappointments. For test purposes, the finest samples procurable were used, including beautiful bodied oils which were air-blown, acid-neutralized, deblumed, grease-rectified, etc., especially fixed for protective paint-making. They would seemingly build up fairly well in the coating process but when it came to floating them off, the paint body would sweat away leaving nothing viscous but a glaze of under dried-on admixtures to float off.

Grease oils—We will only include in this paper the commercially known and used heavy-bodied fish oils, which in film making are handled very much like heavy-bodied linseed. When filmed, the better grades of refined fish oil would build up a heavy film with less coats than any of the other oils under test. The method of handling the fish oils was similar to all other oils: by applying with a brush, repeating the coatings. When the desired number of coats were on, the films were racked until ready to float off. These always required more drying time than the best and worst of the lighter bodied oil substitutes. But, as the drying power of the japans used was the principal object of interest in the grease-oil tests, there was little attention paid to the slower oxidation of the fish oil racked films. Many of the films of the better grades of refined fish oils were beautiful in body and appearance. In the impracticable slow-drying tests, the record kept showed that there was but little volatile loss. As the oils had not been excessively heat-combined with other material, the films had but little tac. Taking the oil tests all together, it is predicted that the future best fixed paint oil for protective paints will include the refined fish oil as an oxidizing retarder that will give results not experienced today in protective paint for structural metal. The writer is convinced of this and also predicts that the use of any kind of oil in combination, when studied out, will make the manufactured combined oil the best on a staple priced market. The desired combined oil will be a viscous quick set-up, in order that it may be used safely by heavy brush or mechanical application without the prejudice usually encountered today. There will be no excessive thinning or rubbing out. The applied body of protective paint will be a tough elastic film, oxidizing from the bottom out which cannot be had by a light-bodied paint unless at unnecessary labor cost. It will not be a question as to how much a gallon of paint will cover, but how long it will last.

Varnish films—As a good grade of varnish is usually tough and elastic, there is never any trouble in floating off. A pure linseed, hard or soft fossil gum combination, will turn white when floated off, but will naturally dry on a line in a day or two. In removing varnish films, if large, they must be stripped squarely with the wood along the top, so as to prevent the water-softened film from sagging irregularly while drying on the line. A small film of two or three coats is sufficient for a shop paint or varnish test. For large reference tests, to be handled repeatedly, apply eight or ten coats according to the weight of the varnish filmed. The oxidizing loss in making varnish films was found to be from 50 to 60 per cent. The protective paint loss will average about 33 per cent.

Shellac films—Shellac films were made to detect the purity of the gums. It was discovered that the smelly, so-called mineral distillate denatured alcohol, made a tougher wearing shellac and retarded the drying but slightly. It also helped the working qualities, owing to its slower volatility which was very noticeable in film tests and considerably so when compared with the films made with wood alcohol, denatured alcohol, or the grain proof, spirit quick volatiles. A film made from pure hard gum shellac will not stretch much on the line. An adulterated soft gum will stretch and may ruin the test film. All shellac films, owing to taking up oxygen on both sides on removal, soon become brittle with but little time variation.

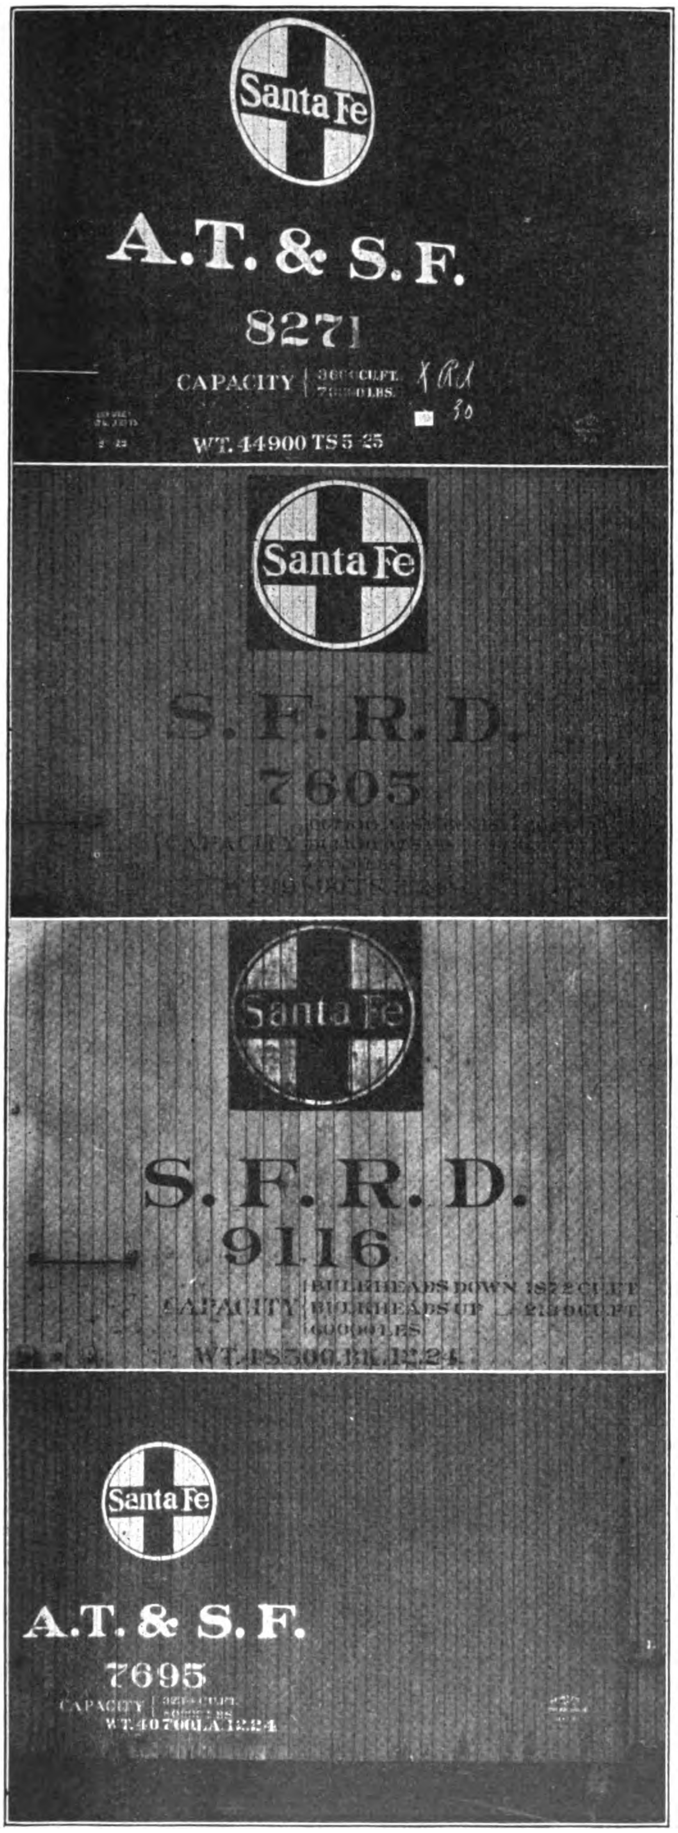
Lacquers—In the old days of the brass-trimmed coach, films were made in the buffing and plating department of what was called dipping and baking lacquers, in order to ascertain the body weight of competitive priced lacquer offerings. The more recent introduction of kindred lacquer specialties, designed for weather exposure in the form of a complete quick surfacing system, and complete finishes, threatens to displace the old-time paint and varnish surfacing systems, as is indicated today by its large and rapidly increasing use in automobile and like surface paintings. It evidently is making good in the demand for quicker surfacing methods.

Damar varnish—The purity and elastic quality of Damar varnish can be film tested like shellac gum. If material other than hard Batavia gum is used, the softer adulterant gums will show granulation in the water floating-off process, through the film's wet surface which to the eye will disappear when dried out. Without essential binding admixtures, such stuff is not fit to use for any purpose, as the best hard-gum Damar varnish made is not any too good in a car paint shop.

Tar films—Natural and manufactured tar films were taken off to ascertain their protective and fire-repelling qualities. Commercial preparations as well as shop-prepared products of good coal tars further reduced in viscosity by a gentle heat evaporation to eliminate the ammonia as much as possible, were the carrying vehicles, with a little fish-oil as a binder and slow-up. Asbestos and magnesia fibre, in dust form, were used freely as the proposed fire-proofing material. A heavy one-coat paste was usually knifed on. As both natural and manufactured tars are heat by-products, the fire-resisting qualities of the removed films were wonderful, especially in locomotive spark and cinder abrasion resistance, but the sterling worth of the tar coatings, owing to the appearance, did not meet with official recognition at that time.

How to make films

The method and equipment for making films is very simple. A shallow water-tight box of a size to float off the largest film wanted, consists of square frames made of wood strips two inches wide and of any desired length. It is covered with tightly stretched cheesecloth and tacked along the edges; then smooth-surfaced stout paper is



Examples of box car lettering submitted to show the comparative weathering qualities of titanox and white lead paint

tacked over the cloth. Several coats of glue sizing, of about five ounces of dextrine, fish, white, or other light colored glue to the gallon of water, is then heated and applied with a brush. There should be no runs or missing in applying the sizing. For making small shop films, plates of glass or tin which have been wiped dry with oil or vaseline, may be used, but there is liable to be trouble in pulling the films off.

Report of the Committee on Tests

This committee suggests that the film test has a value that will warrant its careful study. The paint pigment action on oil can be settled in a few years by aid of the removed film test to the satisfaction of the interested craftsmen that do or do not believe that paint failures can be charged to suspected pigments and that they actually destroy the oil. The problem should be settled beyond all doubt by the consistent outdoor exposure of removed films, owing to the fact that the exposed film is taking in oxygen from both sides which rapidly determines any deteriorating pigment action on oil.

Substitute for shellac

The committee tested several substitutes for shellac and has not as yet found one that compares favorably for all purposes and all classes of work. Shellac is used for so many different purposes—that the procurement of one grade of material which will meet all requirements is an advantage.

Spirit lacquer is a spirit varnish intended to do the work of shellac for first coating, sealing and priming purposes. It is made of fossil gum and high proof alcohol. It may be used for brush, mechanical or dip work. It is recommended that this material be given special study by the committee next year.

Substitutes for white lead

Titanox—In a minority report of the test committee last year, a report was made on titanox, describing its composition and tests were submitted to prove its superior whiteness and covering power. It was evident that there were only a few in the convention that had any experience with this material and the subject was referred to the test committee for further experiments.

Your committee reports that from information obtained from widely separated points, it is generally agreed that titanox is far better in covering power than white lead. It covers about one-third more surface than white lead.

At the Topeka shops of the Atchison, Topeka & Santa Fe, titanox has been standard for over two years for stencilling freight equipment and for the painting of railroad crossing signs, whistling posts, ceilings of baggage and mail cars, interiors of dining cars, kitchen and pantry, as well as other places where a first class durable white paint is desired. The illustration is submitted as evidence of the durability of titanox, as well as of its clear white color as compared to lead. Car, S. F. R. D. No. 7,605, shows a Santa Fe monogram which was mechanically painted with titanox in March, 1924; Car S. F. R. D. No. 9,116, was stencilled with white lead by brush in December, 1924, in Bakersfield, Cal. Box car No. 7,695 shows the monogram initials of the road in mechanically applied titanox, the number and other stencilling was stencilled with lead applied by brush. This car was painted and stencilled in November, 1923, at Topeka, Kan., as you will note by the stencil to the left of the car door. You will also note that the latest light weight was stencilled on in Los Angeles, Cal., December, 1924.

We know that acid fumes will darken white lead. No-

reliable contractor will use it in the interior of kitchens and expect it to retain its color.

The good points of titanox paints were outlined in the preceding paragraphs. The following are what might be termed the weak points. A mixture of the two component parts that compose titanox; namely, titanium oxide and barium sulphate, require reinforcing with zinc and other materials to get the best results. When applied by themselves they dry very slowly and chalk freely. Titanox paint will not sandpaper as easily as lead, but the dust has no poisonous effect on the workmen.

B. E. Miller of this committee, reports that he received some titanox that turned a light pink or brownish cast when used in stencilling freight equipment. In the opinion of your committee, this is not common in titanox, as the illustration clearly proves, and after diligent inquiry we can find only one other instance where free iron was found in the pigment. This is reported by W. O. Quest, who states that in the great amount of this material he has used and tested he only found one small batch that contained iron, and a short time after application it had the same discoloration as that reported by Mr. Miller.

Panels exposed Nov. 24, 1924.

There has been doubt in the minds of some whether or not this material is as cheap as white lead. When we consider that the difference in cost per pound in paste form is only from 2 to 2½ cents, and that it is generally conceded that a 100 lb. of titanox will make at least one gallon more paint than 100 lb. of white lead and that this mixture will cover a third more surface than the white lead, your committee can see no reason why paints with a titanox base should not be given preference for many purposes over those containing white lead.

Undercoatings for pyroxalin lacquer finish

Your committee, to which was referred the question of pyroxalin lacquer under-coatings, reports that search was made of all available sources for information as to the possibility of getting a lacquer system of primers and surfaces as under coatings, either for pyroxalin lacquer finishes, or the long oil enamel, or a varnish system for finishing railroad equipment. The information received from the original producers of the pyroxalin system was discouraging. But it was recognized that if there was any merit in the lacquer method, the greatest saving of time required to finish a job could be made in extending the method to the under-coats. We made further inquiries and learned that one paint manufacturing firm was specializing on lacquered surfacers. We have tested its method on a number of cars with the following results as to time:

First day—Prime putty and knife-in where needed. If the car has been knifed-in all over, only one coat of surfacer is required which should be applied on the second day.
Second day—If the liquid surfacer is required to fill up a smooth surface, two or more coats should be applied.
Third day—Rub with wet or dry sandpaper.
Fourth day—Apply one coat of enamel body color.
Fifth day—Letter with gold leaf.
Sixth day—Apply first coat of wearing body varnish.
Eighth day—Apply second coat of wearing body varnish.
Tenth day—Car placed in service.

This method saves at least four days' time and gives the same general appearance that first-class railroads have heretofore obtained with the old time surfacer system and varnish methods.

If the pyroxalin lacquer finish was applied over the above surfacer system, it would mean that on the fourth day we would apply three coats of lacquer; on the fifth day we would apply gold leaf letters and figures; sixth day, pencil varnish over letters and figures; eighth day, apply second coat of varnish over letters and figures, the car being placed in service on the tenth day.

You will note that the lacquer finish does not save any time as compared to the varnish finish but is handicapped by the fact that it is practically an impossibility to apply sufficient varnish with a pencil to properly protect the gold leaf letters and figures. If a car is lettered and numbered with enamel colors, the car can be finished on the sixth day and placed in service on the eighth day. The method recommended by most of the firms who advocate pyroxalin lacquer finishes is to bring a car up as follows:

First day—Prime.
Third day—Apply body coat.
Fourth day—Putty and knife-in.
Fifth day—Apply surfacer coat.
Sixth day—Rub with wet or dry sandpaper.
Seventh day—Apply three coats of pyroxalin lacquer.
Eighth day—Letter and number with gold leaf.
Ninth day—Varnish over letters and figures.
Eleventh day—Varnish over letters and figures.
Thirteenth day—Car placed in service.

This saves one day's time over our present methods but does not give equal protection to the gold leaf letters. Therefore, the only object any one can have in using this method is the claim that the lacquer finish is practically indestructible and is more easily cleaned. These two claims are yet to be verified by actual experience. On the other hand, the pyroxalin under-coats not only save time in shopping but a smooth surface is obtained with less labor. The durability of this method, however, is questioned by many who have experimented in its manufacture. There are cars that have been in service for eleven months on which this primer and surfacer have been applied that show no deterioration.

If the claim made in regard to durability and ease with which the lacquer finish can be cleaned is substantiated by experience, your committee would suggest that it might be a satisfactory finish where enamel lettering colors are used.

Your committee having read the warning sent out by the insurance underwriters in regard to the use of these lacquers wishes to state that while we believe their warning is overdrawn and that they are making demands not in accordance with past practices in handling materials that are in our opinion more inflammable than the pyroxalin lacquers, we do endorse their recommendation that a segregated portion of the shop be equipped with an efficient ventilating system for the application of pyroxalin lacquers.

What paints are the most effective and cheapest for the preservation of metal surfaces?

The question of protecting steel cars from corrosion is becoming more important every day. This is due to a realization of the necessity of conserving our natural resources and reducing the expense of corroding steel cars and structures of various kinds that have to be replaced.

The only way of preventing steel from going back to its original state, is to protect the steel by an efficient film of paint to prevent the access of oxygen, sulphur, other gases and water to the surface of the steel. The paint film should, as far as possible, be a non-conductor to prevent any electrical action. After rusting has started it is difficult to stop. This action, while retarded, is not completely checked by painting over the rusted parts.

There have always been many opinions as to the best paints to use for the preservation of metal surfaces and the effect of using inert materials, such as asbestine, calcium carbonate, china clay, etc., which have a tendency to cheapen the paint mixtures. Some say they destroy their efficiency and others say they reinforce and make them more efficient. A number of paints were made up in Roanoke, Va., shops of the Norfolk & Western and applied to a series of 36 steel panels 10 in. by 16 in. by 1/16 in.

It was decided to use for the test the following pigments: basic lead chromate, sometimes called American vermilion; red lead, lamp black, metallic brown or iron oxide and blue lead. It was decided to use an inert extender in different proportions to cheapen the cost of the paint mixtures and to determine what quantities of extender might be used without reducing the efficiency of the paint. The idea was to select an extender that would answer for all mixtures. On account of its general characteristics and structure or form, asbestine was selected as the most suitable material for the purpose.

Boiled linseed oil was used as the vehicle for all mixtures except the red lead mixtures and one panel painted over red lead with a paint made up with a fair grade of paint reducing oil. All mixtures were ground reasonably fine except the red lead. In every case the red lead was mixed according to the Norfolk & Western standard formula; i.e., 20 lb. of dry red lead mixed in two quarts raw linseed oil to a paste, allowed to stand over night, thinned for use with one pint of raw linseed oil and one pint of turpentine. This mixture weighs exactly 26 lb. to the gallon and should be freshly mixed every 48 hrs.

A description or chemical analysis of the material used is shown as follows:

Red lead	True red lead (Pb_3O_4)	91.82
	Lead oxide	8.90
	Undetermined	.18
Boiled oil	Specific Gravity	.934
	Flash	545°F
	Iodine number	180
	Color O. K.	
	Odor O. K.	
	Manganese present.	

Turpentine—Pure.
Lamp black—Good quality, approximately 97 per cent carbon.
Blue lead—Lead sulphate one of the standard brands.
Oxide of iron—Sesqui oxide of iron 48.25 per cent, remainder siliceous material.
Basic lead chromate—Is a composition of approximately 33⅓ per cent each, basic lead chromate, lead sulphate and lead carbonate.

No dryer was used in any case. All proportions of the extender were calculated by volume. All panels were sandblasted and received three coats.

The cost of these paints varied from approximately $0.80 to $3.50 a gallon.

The table shows what paint was applied to each panel and also the drying time allowed. The panels were exposed on the roof of the paint stock house with a southern exposure for about 10 months and, as we expected, they do not as yet show any marked developments. This test is now being extended to include the straight basic lead chromate, basic lead chromate with different proportions of iron oxide, different proportions of silica, also asphalts, oilsonites, ets., over rusted surfaces.

The report was signed by the chairman, James Gratton, general foreman painter, B. R. & P.; John McDowell, foreman painter, C. R. I. & P.; J. W. Gibbons, general master painter, A. T. & S. F.; B. E. Miller, master painter, D. L. & W.; Marceau Thierry, foreman, paint shop, N. & W.; L. B. Jensen, general foreman, passenger department, C. M. & St. P.; Thos. M. Davies, foreman painter, S. P.; F. B. Davenport, foreman painter, Penna.

IN RESPONSE to a letter from W. J. Harahan, chairman of the railroads' train control committee, urging a postponement of the effective date of the second train control order requiring the installation on the second division of the original 45 roads, the Interstate Commerce Commission has declined to entertain a blanket petition; but this does not prevent the filing of petitions by individual roads.

Decisions of the Arbitration Committee

(The Arbitration Committee of the A.R.A. Mechanical Division is called upon to render decisions on a large number of questions and controversies which are submitted from time to time. As these matters are of interest not only to railroad officers but also to car inspectors and others, the Railway Mechanical Engineer will print abstracts of decisions as rendered.)

Proper charge for replacing second-hand cast steel wheels with new cast iron wheels

On August 22, 1922, Louisville & Nashville box car No. 16859 was repaired, a change of wheels being made on account of a cut journal. One pair of second-hand Davis cast steel wheels mounted on a second-hand A.R.A. standard axle were removed and replaced with new cast iron wheels mounted on a new A.R.A. standard axle. The charges, amounting to $182.61, representing the difference in value of the axle and wheels removed and those replaced, were assessed against the car owner by the Charleston & Western Carolina, the repairing line. The C. & W. C. contended that the charges and credit for this repair were made in conformity with Supplement No. 1, Items 192, 193 and 197, Rule 101. The repairing line assumed responsibility for the cut journal and restored the car to its original condition and then gave the car owner credit for the scrap axle at second-hand value. It therefore contended that the additional expense due to the application of new wheels and a new axle should be borne by the car owner as the repair constituted a betterment to the car. The L. & N. contended in its statement that the charge for the new wheels and axle applied should not have exceeded that of second-hand material as this repair work was nothing more than an ordinary case of wheels changed on account of a handling line defect.

In rendering its decision the Arbitration Committee sustained the contention of the L. & N. and stated that the principle of interpretation No. 5 to Rule 98 (1921 Code) applies.—*Case No. 1337, Charleston & Western Carolina vs. Louisville & Nashville.*

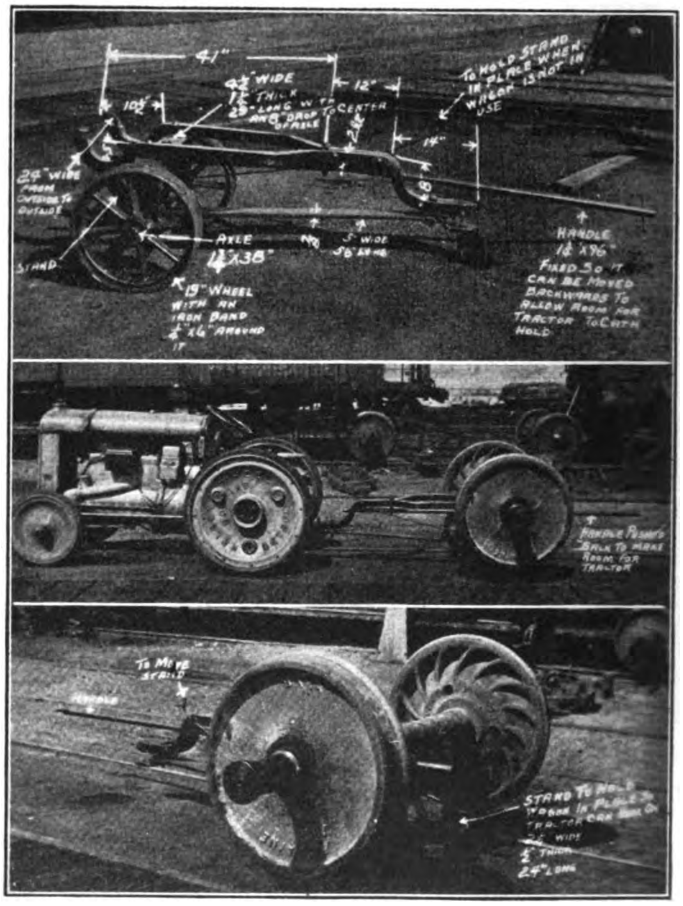
Another case under Rule 32

Chicago & Northwestern stock cars Nos. 17153 and 17347 failed while being handled by the Baltimore & Ohio. Car No. 17153 was broken in two, one end dropping on the rails. Both cars were practically destroyed. The B. & O. reported the cars under Rule 112, claiming that the damage to the cars was the owners' responsibility. The car owner objected to this, stating that when the handling line wrecking foreman arrived at the point of the accident, he found that car No. 17153 was broken in two with one end on the ground and the truck shoved back towards the opposite end of the car. This condition constitutes unfair usage within the intent of Rule 32, and places the responsibility for the damage to both cars with the handling line. The handling line stated that the cars were handled in a train of 38 loads and 55 empties. The train was moving at six miles per hour and approaching a crossing when the engineman discovered a signal against his movement and made a service reduction of 10 lb. which caused the slack to run in and buckle the two cars in question. The cars were not cornered, sideswiped, derailed, or in any other way damaged, which under Rule 32, would make the handling line responsible. The B. & O. further contended that all the damage was sustained before the end of the car dropped on the rail.

In rendering its decision the Arbitration Committee stated that the handling line is responsible. Arbitration decisions 1186 and 1236 apply.—*Case No. 1342, Chicago & Northwestern vs. Baltimore & Ohio.*

Transporting wheels with a Fordson tractor

The delivery of wheels in a car yard can be done more efficiently with proper and adequate equipment than when performed by manual labor. Previous to the installation of the equipment shown in the illustration, wheels were handled at the Curtis Bay, Md., car shops of the Baltimore & Ohio, from the supply track to the car by four men. A short time ago a Fordson tractor was added to the equipment at these shops and in order to speed up the delivery of wheels as well as to perform this work more economically, two car repairmen and an apprentice built the wagon shown in the top view



Tractor wheel trailer built for making deliveries from the supply track to the car

of the illustration. We are indebted to W. W. Calder, district master car builder, Baltimore & Ohio, and to the Baltimore & Ohio magazine for the photographs and description of this wagon.

The wagon consists essentially of two cast iron wheels and a chassis on which provision has been made for carrying the wheels on one end while the other end couples directly to the tractor. The important dimensions and details of construction are shown in the top view of the illustration. The wagon is also provided with a handle so that it can be pulled by two men. This handle can be moved back out of the way when the wagon is coupled to the tractor.

Southern increases its car repair facilities

New shop at Hayne, S. C., has monthly output of about 80 passenger and 500 freight cars

By A. B. Brown
Westinghouse Electric & Manufacturing Company

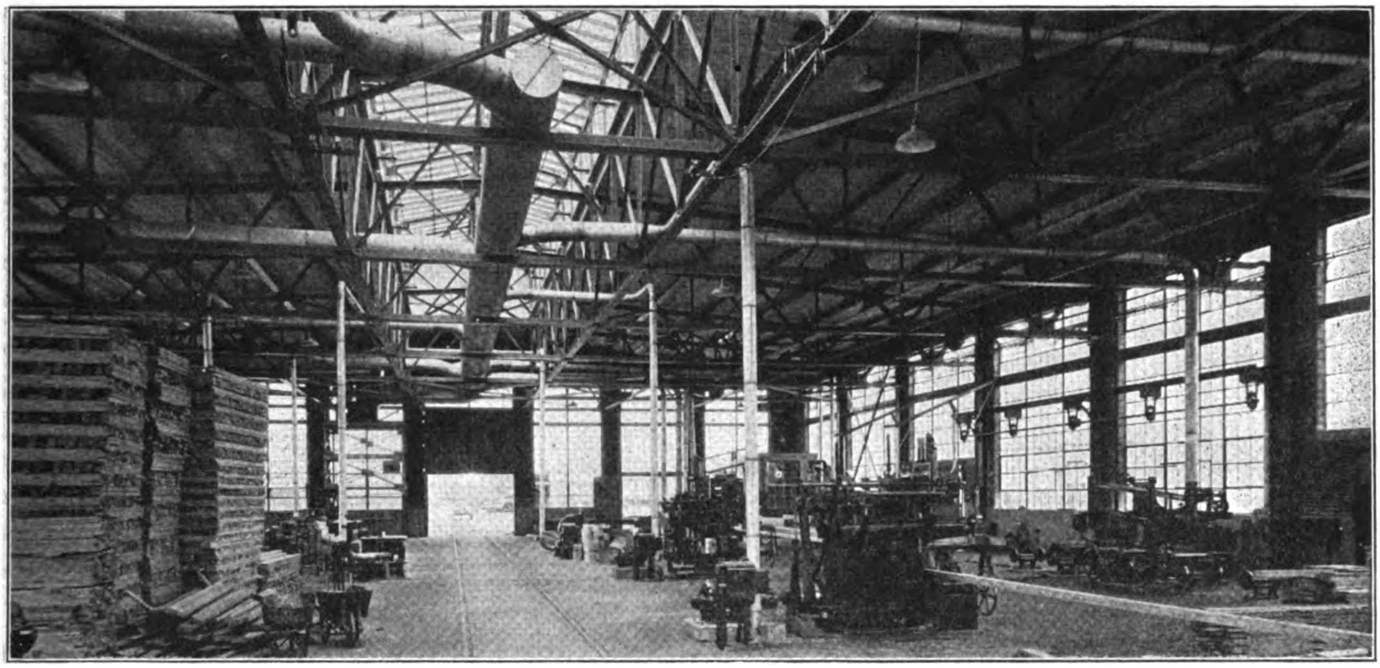
THE Southern Railway, in carrying forward an extensive improvement program, has increased its car repair facilities by the addition of a new shop at Hayne, located near Spartanburg, S. C. This shop was placed in operation, January 2, 1925, and is equipped to handle repairs for both passenger and freight cars. Since that time, it has taken over the work which was formerly handled at Columbia, S. C., and now has facilities for performing general repairs to about 80 passenger cars and to rebuild 500 freight different type cars per month.

Referring to the layout drawing of the car repair tracks and buildings, it will be noted that the shop is laid out to handle repairs by the straight line system. Cars to be repaired are switched into the repair yard, past the reclamation shop building and scrap dock, and are classified both as to class of repairs and type of car. This system simplifies the actual production work to a great extent when the cars are started through the shop.

The freight car department

The freight car shop, 391 ft. long by 107 ft. wide, is of structural and corrugated steel open construction, affording a maximum amount of light and ventilation. It contains five tracks and has capacity for 40 cars. Heavy steel cars are repaired on track No. 1 which is located adjacent to the fabrication shop bay and is served by a 15-ton electric crane. Tracks No. 2 and No. 3 are also served by an electric crane and are used for stripping heavy and medium repair cars, respectively. The straight-line system is also used for light repair work which is done on track No. 4 while track No. 5 is used for finishing up. Permanent scaffolding is provided for the last two tracks.

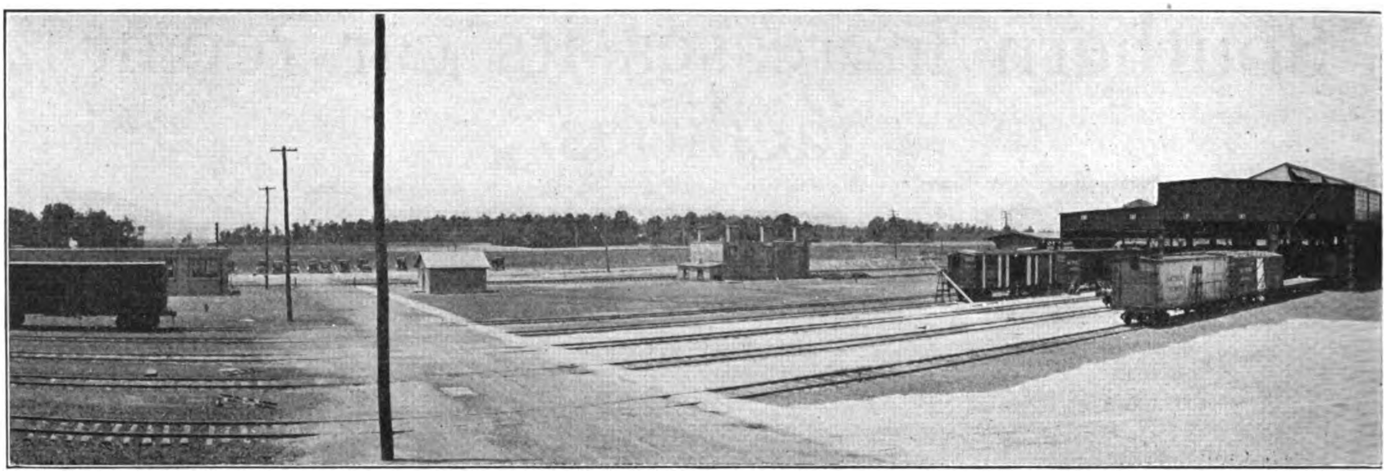
The yards and tracks are so constructed that the cars move on one continuous track practically by gravity from the storage yard through the freight car building to the paint yards. When the cars are placed in the storage yard they are checked up and listed showing the amount of work necessary in order that the material can be gotten out through the different departments, blacksmith and planing mill, in advance of the time the cars are placed for the car repairs. From six to eight days is the average time required for repairing a car; which usually includes one day on the stripping track; three to four days repairing, and two to three days on the paint tracks.



Interior view of the planing mill showing the arrangement of machinery on one side of the mill and the sawdust conveyor system

The planing mill is well equipped

The planing mill is located in a separate building, 100 ft. wide by 162 ft. long and is situated convenient to the freight car repair shop, lumber storage yard and dry kiln, thus effecting minimum hauls to the various points. The building is airy, light and modern in every detail of de-

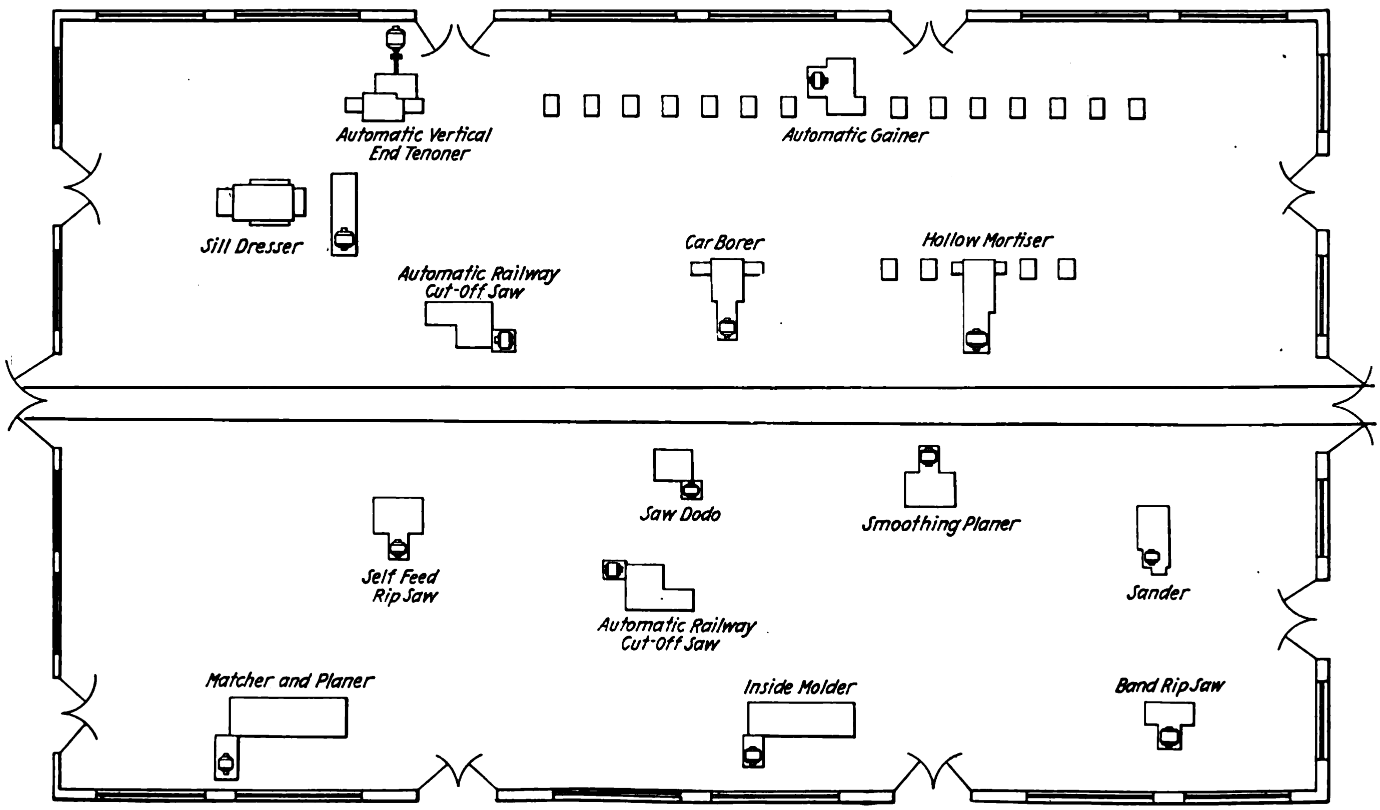


Panoramic view of the Southern Railway's car shops, Hayne, S. C.,

sign. The layout of the machinery is so arranged that the material is carried straight through the different process of cuts without any back-tracking. A suction blower system with pipes to each machine is installed for the removal of sawdust. The sawdust is conveyed to a collector on the outside of the building from which it is removed to cars for shipment.

As can be seen from the layout drawing of the car repair tracks and buildings, there is one supply track running into the planing mill from the lumber yard. The shops are served from here by trucks and tractors as shown in one of the illustrations. After the lumber is machined, it is either taken direct to the car or stored for use when needed. All freight car doors are made in the planing mill and completed with hangers and trimmings ready to be applied to the cars. A steel-top table is located in one corner of the mill where the side doors are assembled. Individual motor drive with automatic push-button control is used on all machine tools. The following equipment is installed in the planing mill:

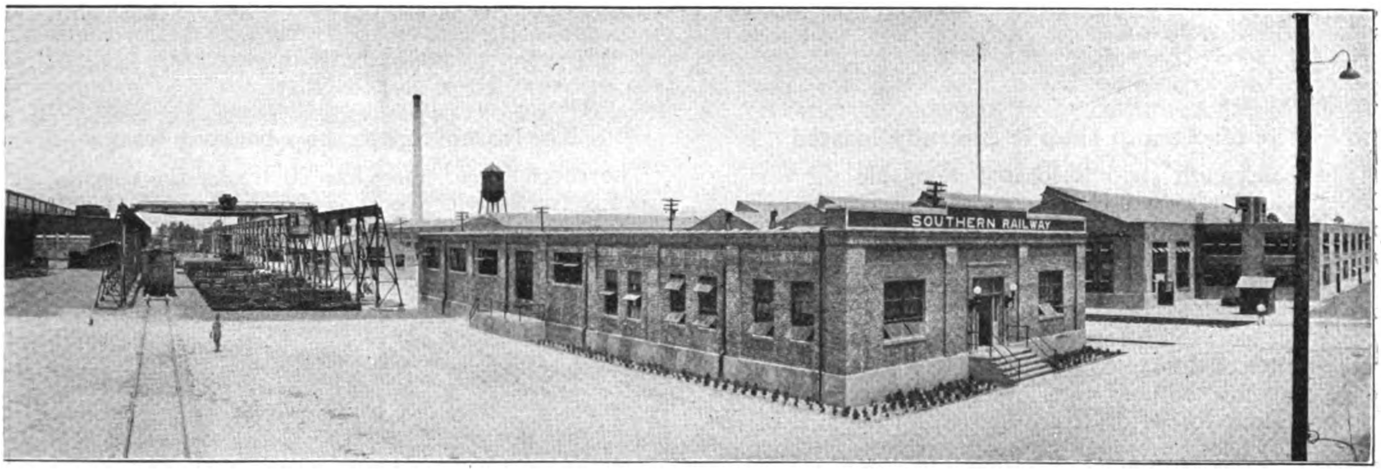
Machine	Manufacturer	Motor drive
90-lb. exhauster	Sturtevant	60-hp. Westinghouse
14-in. matcher	Fay & Egan	50-hp. Westinghouse
36-in. circular saw	Fay & Egan	15-hp. Westinghouse
14-in. by 18-in. planer	Fay & Egan	50-hp. Westinghouse
Tool grinder	Fay & Egan	2-hp. General Electric
Tenoner	Fay & Egan	15-hp. Westinghouse
Gainer	Fay & Egan	20-hp. Westinghouse
Boring machine	Fay & Egan	15-hp. Westinghouse
Mortiser	Fay & Egan	20-hp. Westinghouse
13-in. circular saw	Fay & Egan	5-hp. Westinghouse
36-in. cut-off saw	Fay & Egan	20-hp. Westinghouse
36-in. cut-off saw	Fay & Egan	20-hp. Westinghouse
Machine moulder	Newman	40-hp. Westinghouse
Band saw	Fay & Egan	10-hp. Westinghouse
Sander	Fay & Egan	15-hp. Westinghouse
Tenon machine	Greenlee	15-hp. Westinghouse



Drawing showing the arrangement of machine tools in the planing mill

Kiln for drying lumber

One of the features of the equipment at the Hayne shop is the dry kiln, manufactured by the National Dry Kiln Company, Indianapolis, Ind., for drying lumber used



showing the freight car shop in the center

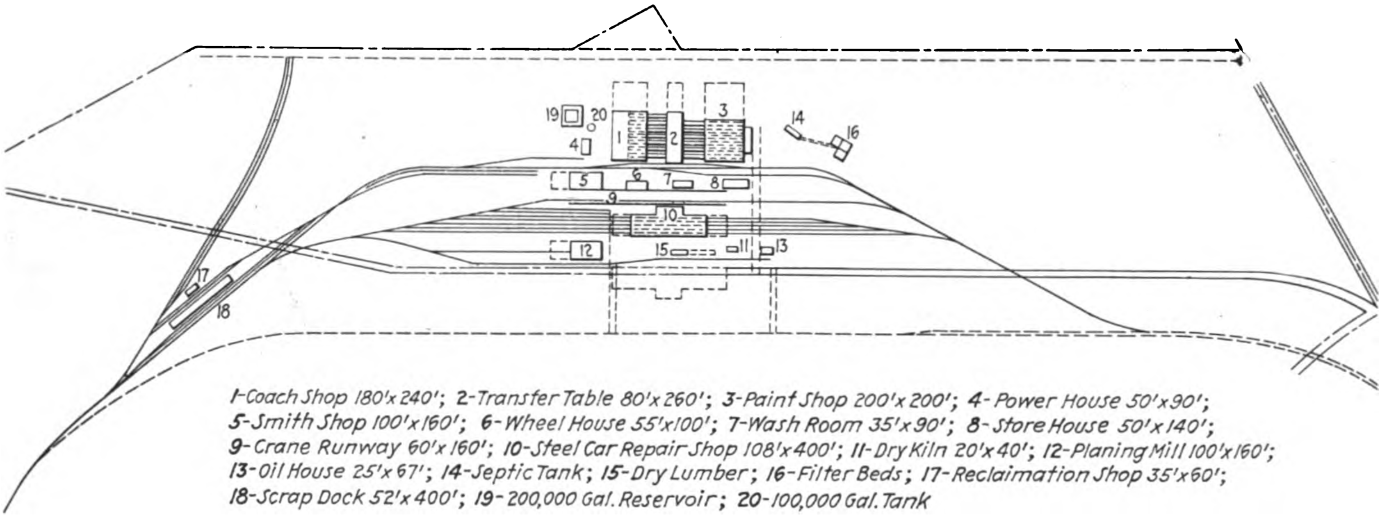
in the repair of passenger coaches and refrigerator cars. The dry kiln is a concrete and brick structure, 40 ft. long by 20 ft. wide with two sliding doors at the front. The kiln contains two tracks where small cars loaded with lumber are placed during the drying period. The drying is accomplished by heat from a double layer of steam pipes under each track. A 3-in. water spray pipe with small holes drilled in each side is located just above the steam pipe.

The lumber is systematically loaded on the cars to allow a maximum amount of air circulation. Careful tests are made and records are kept both before and during the drying period from sample pieces which are chosen from different sections of the pile. A piece is cut off one foot from the end and then the sample piece is cut off for testing on a special scalometer or Evapercenter. From four to six samples of board are tested, tests being made at intervals of from 24 to 48 hrs. The fresh ends of the sample boards are then painted with graphite paint mixed with rosin to prevent drying out at the end. When the final tests have indicated that the moisture content of the stock is down to the desired point, the Moistat is shut off, the heat cut off, and the ventilation closed. The stock is then left from 12 to 24 hrs. with the Moistat and ventilation shut off.

The Moistat is a self-contained thermostatic device for regulating the temperature of the kiln. Its power is obtained from expansive volatile liquids which are sealed in the instrument. These liquids expand and generate pressure in exact proportion to the temperature surrounding the thermostat.

The lumber is allowed to dry itself as long as it gives up its moisture readily. After a time steam is required. The instrument is sensitive to this need through the thermostat, allowing steam to pour into the kiln. This continues until the wet bulb temperature is raised sufficiently to generate a pressure which will be ample to tightly close the valves.

The operating room where tests and records are made adjoins the dry kiln in the rear. Here, is also placed the Moistat regulating device for regulating the temperature of the kiln.



Layout of the car repair tracks and buildings

The fabrication shop

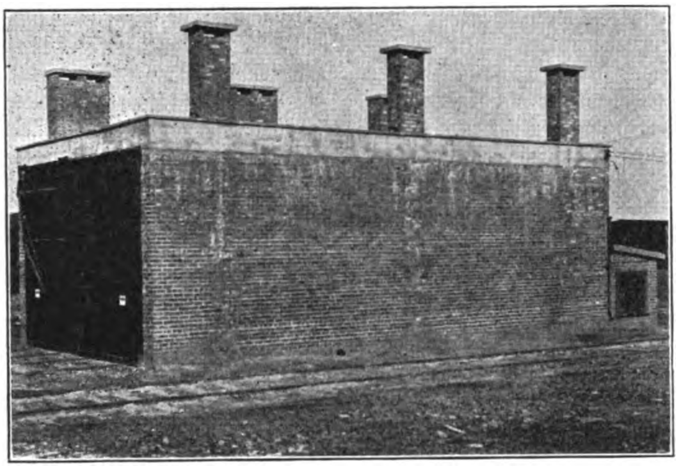
The fabrication shop for working and assemblying metal material used in the repair of steel cars and heavy repairs of wooden cars is built as an annex to the freight car shop proper. The shop is 51 ft. wide by 115 ft. long with one side opening into the freight car shop adjacent to tracks No. 1 and No. 2 where the heavy repairs are made. Both the blacksmith shop and casting docks are situated near the fabrication shop so that the production on metal work may not be delayed by long haulage. The fabrication shop contains the following equipment:

Machine	Manufacturer	Motor Drive
Shear	Cleveland	10-hp. Westinghouse
Drill press	Manning, Maxwell & Moore	3-hp. Westinghouse
Radial drill	Reed Prentice	5-hp. Westinghouse
Punch	Cleveland	10-hp. Westinghouse
Straightening press		

The blacksmith shop is centrally located

The blacksmith shop is located alongside the casting docks where material can be conveniently reached and stored. The building, which is 100 ft. long by 60 ft. wide, is a fire-proof structure of modern design, well lighted and ventilated. It is completely equipped with modern equipment.

Sixteen blacksmith forges are arranged in double rows in the center of the building with ample room around each forge to work without interference. Pressure blowers for providing forced draft are located on the side of the building. There are four high temperature oil burning furnaces placed at convenient points throughout the shop. Oil is pumped from an underground tank to the furnaces by a steam driven oil pump. Exhausts through the roof are provided for the 1500-lb. and 3400-lb. steam hammers. The blacksmith shop was planned with ample capacity to



Kiln for drying lumber to be used in the repair of passenger and refrigerator cars

take care of any future additions that might be made to the car repair shop. The equipment consists in part of:

Machine	Manufacturer	Motor Drive
Turbo considal	Buffalo	7½-hp. Westinghouse
Type R pressure blower	Buffalo	20-hp. Westinghouse
Hammer	Bradley	10-hp. General Electric
Bulldozer	Williams & White	20-hp. Lincoln
Bolt header	Williams & White	16-hp. General Electric
Punch and shear	New Doty	15-hp. Triumph
200 ampere arc welding set	Westinghouse	

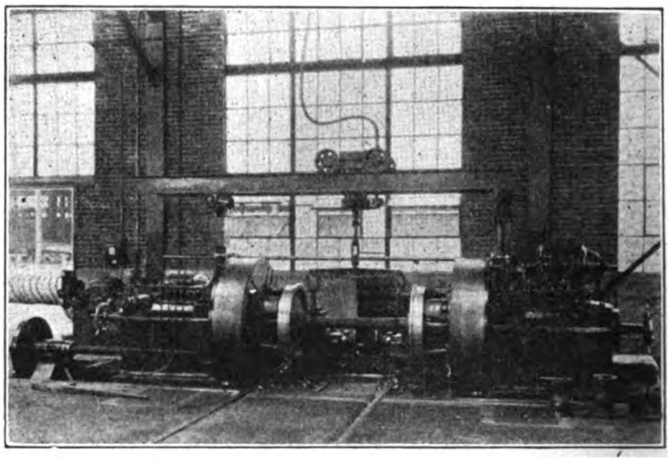
Wheel shop serves for both freight and passenger car repairs

The wheel shop which serves both the freight car and coach repair shop is situated between the two and is readily accessible to both of these departments. There is sufficient storage space for mounted and unmounted wheels and axles. An electric traveling crane serves the storage platform. Like the blacksmith shop, the wheel house was designed to take care of future production far exceeding the present output. The building is 102 ft. long by 55 ft. wide and is of the same general construction as the blacksmith shop and planing mill. Space has been provided for the future installation of an additional axle lathe and boring mill. The equipment includes the following:

Machine	Manufacturer	Motor Drive
Car wheel lathe	Niles-Bement-Pond	50-hp. Westinghouse
Car wheel lathe	Niles-Bement-Pond	10-hp. Westinghouse
400-ton wheel press	Chambersburg	10-hp. Westinghouse
Car wheel borer	Putnam	15-hp. Westinghouse
Axle lathe	Niles-Bement-Pond	15-hp. Westinghouse
18-in. lathe		Westinghouse
26-in. drill press		Westinghouse
32-in. shaper		Westinghouse

The coach repair shop has ten tracks

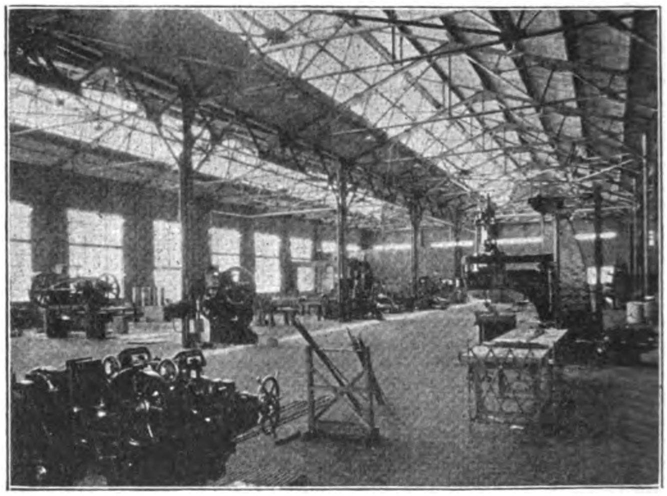
The coach repair shop has 10 tracks for coaches and two for trucks which occupy about one-half of a building, 180 ft. wide by 24 ft. long. The roof is of the saw-tooth design, with skylights on one side of each tooth



Niles-Bement-Pond car wheel lathe installed in the wheel shop

which affords good light and ventilation. Permanent scaffolding is suspended from each column between the tracks. The cross arms of the scaffolds are counterbalanced by weights, enclosed in a casing which protects them from outside interference. Seventeen holes are drilled in the uprights affording adjustments for any desired height of scaffolding.

All passenger cars are brought into the yard and



Coach machine shop—The pipe, tin and cabinet shops are located in the rear

placed on the stripping tracks. At the present time the stripping is done in one side of the paint shop because of the nearness of this location to the different departments for cleaning and painting the coach accessories. The upholster work is taken to the upholster shop and the trimmings to the wash rack. The trimmings are afterwards moved to the paint shop and prepared for re-application to the car.

After the car is stripped it is moved to the outside of the building on a length of track between the transfer

table and paint shop, where the trucks are removed from one end and emergency trucks are substituted. The car is then taken over the transfer table to the opposite side of the tracks where the remaining trucks are removed and emergency trucks are installed. The trucks are then taken to the truck shop for overhauling, and the car to the coach shop for necessary repairs. When the work has been completed on the coaches they are placed back in the paint shop for painting and re-applying the upholstering and trimmings.

The coach machine shop and cabinet shop are located in the same building

The coach machine shop, cabinet shop, tin and pipe shops are located in the coach repair building. This location is advantageous because of its accessibility to the repair tracks. Modern metal and woodworking machinery are used throughout, all of which are equipped with individual electric drive and push-button control. The following is a list of tools in the cabinet shop:

Machine	Manufacturer	Motor drive
Shaper	Fay & Egan	5-hp. Westinghouse
Cabinet planer	Fay & Egan	15-hp. Westinghouse
Band saw	Fay & Egan	5-hp. Westinghouse
Universal worker	Fay & Egan	5-hp. Westinghouse
Universal cabinet saw	Fay & Egan	5-hp. Louis Allis
Molder	Fay & Egan	10-hp. Westinghouse
Mortiser	Wysong & Miller	1½-hp. General Electric
Drill press	Manning, Maxwell & Moore	2-hp. Westinghouse

The machine shop contains the following machine tools:

Machine	Manufacturer	Motor drive
Drill press	Manning, Maxwell & Moore	2-hp. Westinghouse
Shear	Williams & White	10-hp. Westinghouse
Radial drill	Niles-Bement-Pond	10-hp. Westinghouse
Bolt cutter	Acme	5-hp. Westinghouse
Radial drill	Reed Prentice	5-hp. Westinghouse
Angle bender	Ryerson	15-hp. General Electric
Punch and shear	Buffalo	....

The paint shop

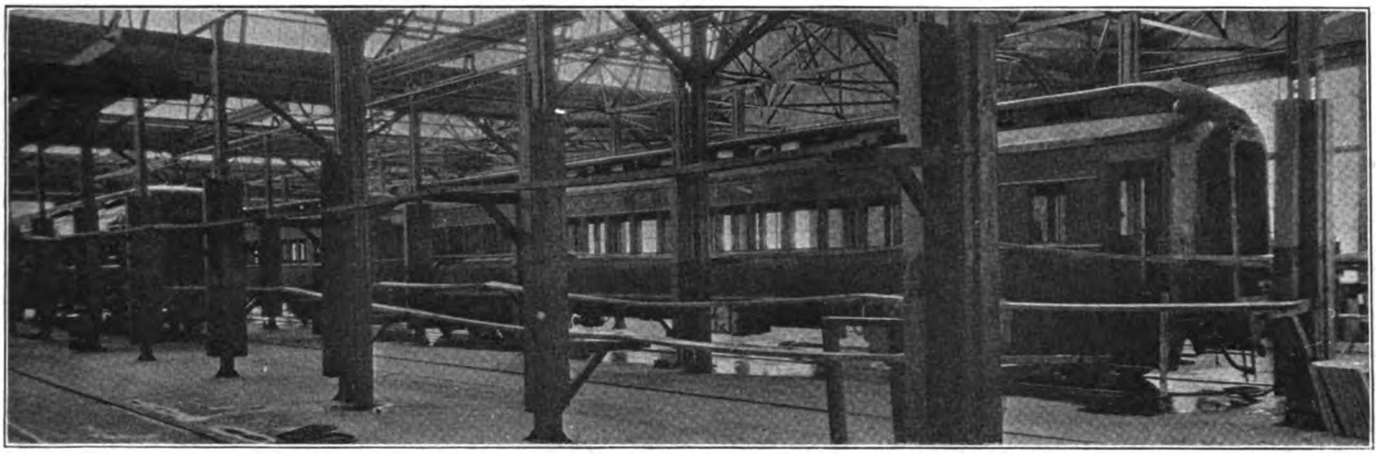
The repaired cars are taken first to an outside track where they are thoroughly cleaned by air and are then taken into the paint shop to be scrubbed. The paint shop has capacity for 20 cars, two cars to a track. Permanent scaffolding, similar to that in coach shop, is provided. The building is heated by steam in cold weather, a constant temperature of 70 deg. being maintained.

In cases where the surface of the wooden coaches is practically gone, the paint is burned off with a kerosene torch. At the present time, paint is removed from steel cars with a paint remover, but it is planned to use sand blast for this work as soon as the apparatus is installed.

Where the surface is in fairly good condition, a primer is put on and allowed to dry for 48 hours. Then coats of No. 2 and No. 3 paint and a surfacing composition are used, in the order named, with intervals of one day between each application. The car is next rubbed to a surface and two coats of body color and two coats of varnish are applied.

If the surface is in good condition, the raw spots are sanded and touched up with a primer. They are then puttied and sanded, after which color and varnish are applied. The trucks and underframes are sprayed after the painting on the coaches has been completed.

A feature of the coach shop layout is the electrically driven transfer table. The table, which is 80 ft. long, is of sufficient length to accommodate the largest coaches. Cars are pulled on and off the table by means of a cable from a drum geared to the main motor. A clutch is provided for disengaging the motor pinion from the main driving gears which transfers the motion to the cable drum. Reversing is obtained with drum control.



Interior view of the paint shop showing the type of scaffolding used in coach repair work

The air brake room

A partitioned space, 22 ft. by 52 ft., in one corner of the coach machine shop is set aside for the air brake room. The equipment includes a universal control rack, triple valve test rack with an auxiliary device and three benches, each 38 in. by 10 ft. A double rack for storing triple valves is placed just outside of the air brake room in the machine shop.

Repaired valves are placed in one section of the rack, while another section is reserved for valves to be repaired. A similar rack is located in the fabrication department of the freight car repair shop in order that the freight cars may be serviced with the least possible delay. This rack is replenished daily.

Department for electro-plating

An electro-plating room is situated in the paint shop building. All brass work such as locks, door hinges, baskets, sash locks and light fixtures are cleaned here. The fixtures are cleaned by boiling in a caustic soda solution. They are then run through an acid solution for brightening. All permanent brass fixtures are next buffed and lacquered, while those requiring an oxidized finish are oxidized with liver of sulpher, run over with a scratch wheel and lacquered.

Here all mirrors and dining car silver are reclaimed and plated. After the silver has been cleaned with Kostico and pumice, it is put in a silver "strike" tank, where a thin coat is applied. It is then dipped into the regular silver tank, taken out and scratched, put back in the silver tank, and finally polished on a wheel. The

same general process is followed for nickel, copper and tin plating with the exception that no "strike" tank is used. The equipment includes a Hanson and Van Winkle, six volt, 100 ampere electro-plating motor generator set and three buffing wheels.

The upholstering department

The upholstering department, where curtains, seats and backs are cleaned and repaired, is located on the second floor, above the plating rooms. The seats are cleaned by a vacuum process. They are then dipped in a cleaner solution and brushed on a high speed rotary brushing machine. Most of the moisture is eliminated by this process and they are drying within two hours.

A novel machine for brushing washed seats is used in this department. It is 4½ ft. long by 1 ft. 9 in. wide and 2 ft. high, having a framework of channel iron. A stiff bristle brush, 9 in. by 14 in. is coupled to a five-hp. motor which revolves at a speed of 1,160 r.p.m. Three two-inch wooden rollers are placed in the front and rear of the brush so the seats may be easily moved back and forth across the revolving brush. The average time for

Fordson tractors are used to handle material

washing the seats and backs of a day coach is 2½ hrs., which is 50 per cent less than the time required by ordinary processes.

Power is secured from the South Carolina Light and Power Company. Two circuits, each 33,000 volts, 3-phase, 60 cycles are available at the sub-station. In the event service is interrupted on one circuit, a change-over can be made to the other circuit, thus assuring continuous power service. The voltage is stepped down through three 500 KVA transformers to 440 volts which is used throughout the shop.

Two 500-hp. O'Brien boilers furnish steam for the dry kiln, steam hammers, heating system and steam-driven air compressor. The equipment also includes a 1,500-cu. ft. motor-driven air compressor. Ample fire protection is assured by a fire pump which delivers 1,000 gal. per min. The plant is provided with a 100,000-gal. tank and a 200,000-gal. reservoir.

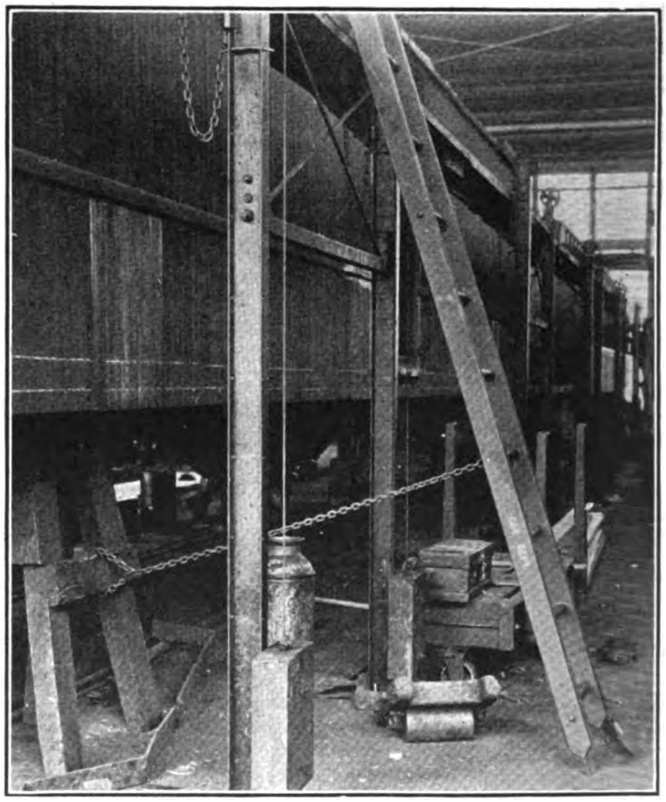
Daily reports are sent to the superintendent's office by each department. In this way a close check is kept on the ratio of production throughout the shop and work can be assigned accordingly.

A foreman's meeting is held once a week. Suggestions regarding new equipment, welfare of the employees and any points which might be of material interest are discussed here. No doubt these meetings have played a prominent part in establishing and maintaining the close co-operation which is evident between the several departments. Much of the credit for the efficient operation of the shop can be attributed to J. O. Johnson, superintendent car shops, who directs its operation.

The Hayne car shop was designed and built under the supervision of H. W. Miller, vice-president, Southern Railway, and R. L. Ettenger, consulting mechanical engineer and assistant to Mr. Miller. Dwight P. Robinson Company were the contractors and constructing engineers.

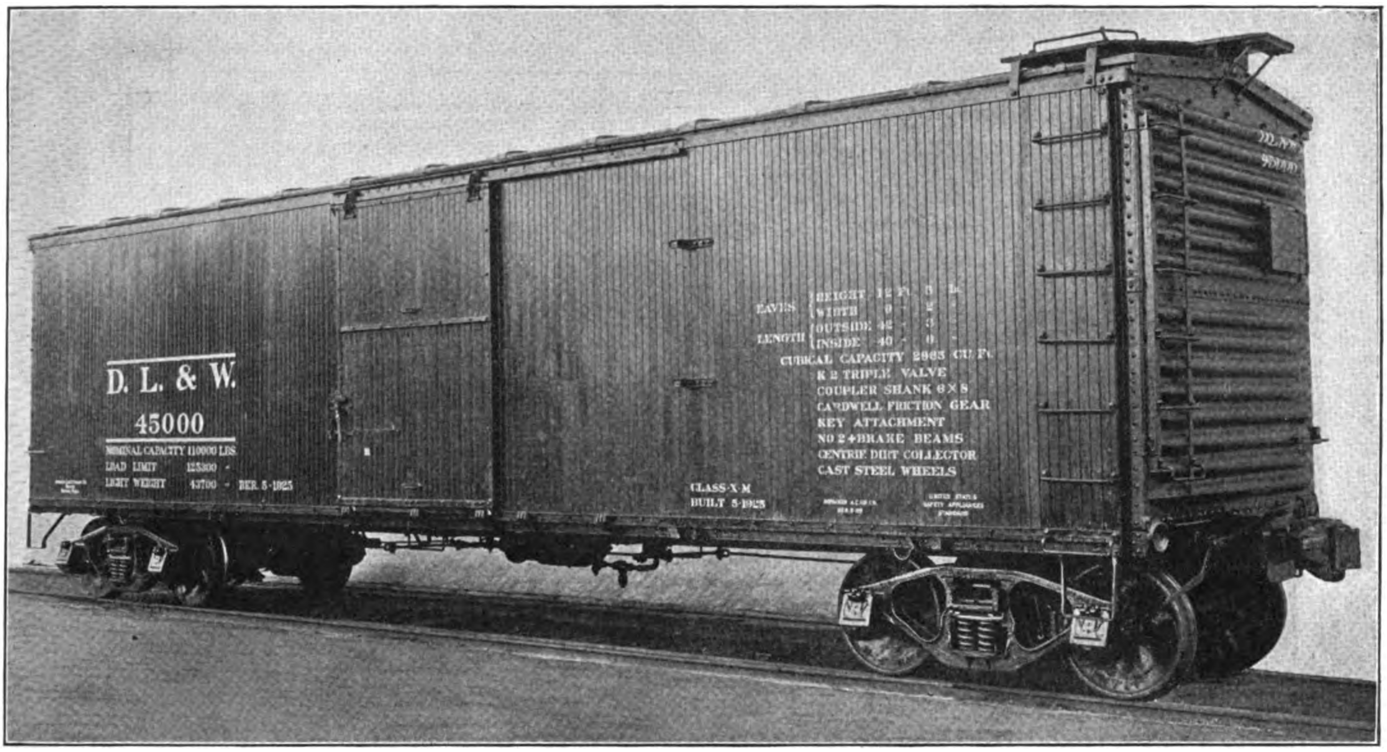
Method of preventing ladders from over-balancing

IT is common practice to provide means to prevent a ladder from slipping on a greasy or otherwise slippery floor. The rail ends of the ladder shown in the illustration are provided with pointed iron grips which is one way of preventing slipping. There is, however, another danger to guard against when using a ladder. In car repair work a ladder is often placed against a scaffolding, as shown in the illustration, so that a portion of



Chain used to prevent a ladder from overbalancing when a workman is on the upper end

it overhangs. The workmen will use the ladder in this position to reach the roof of the car. If the ladder is not properly fastened, his weight on the upper end will cause it to overbalance and result in an accident. A simple but effective way to prevent such accidents is to fasten to the lower end of the ladder a chain, the other end of which is attached to a trestle under the car, as shown in the illustration, or it can be readily fastened to any part of the under construction of the car. The chain is permanently fastened to the ladder, thus preventing it from becoming lost and also eliminating the tendency of a workman of not securing the ladder owing to the fact that there is no chain handy for this purpose.



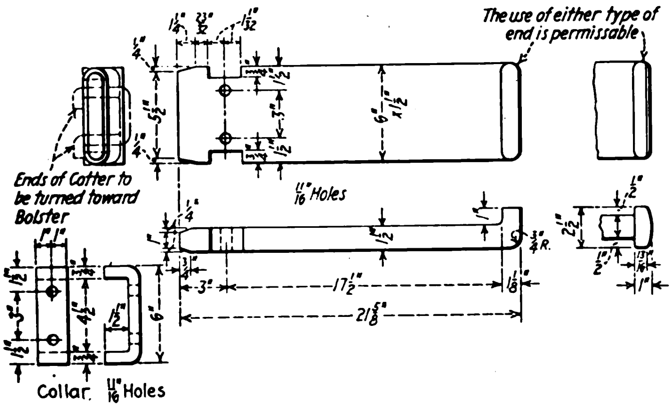
D. L. & W. 55-ton, 40-ft. 6-in., double sheathed box car built according to A. R. A. specifications.

Double sheathed 55-ton box cars for the D. L. & W.

Built according to A.R.A. specifications—Have a carrying capacity of 125,000 lb. and weigh 43,700 lb.

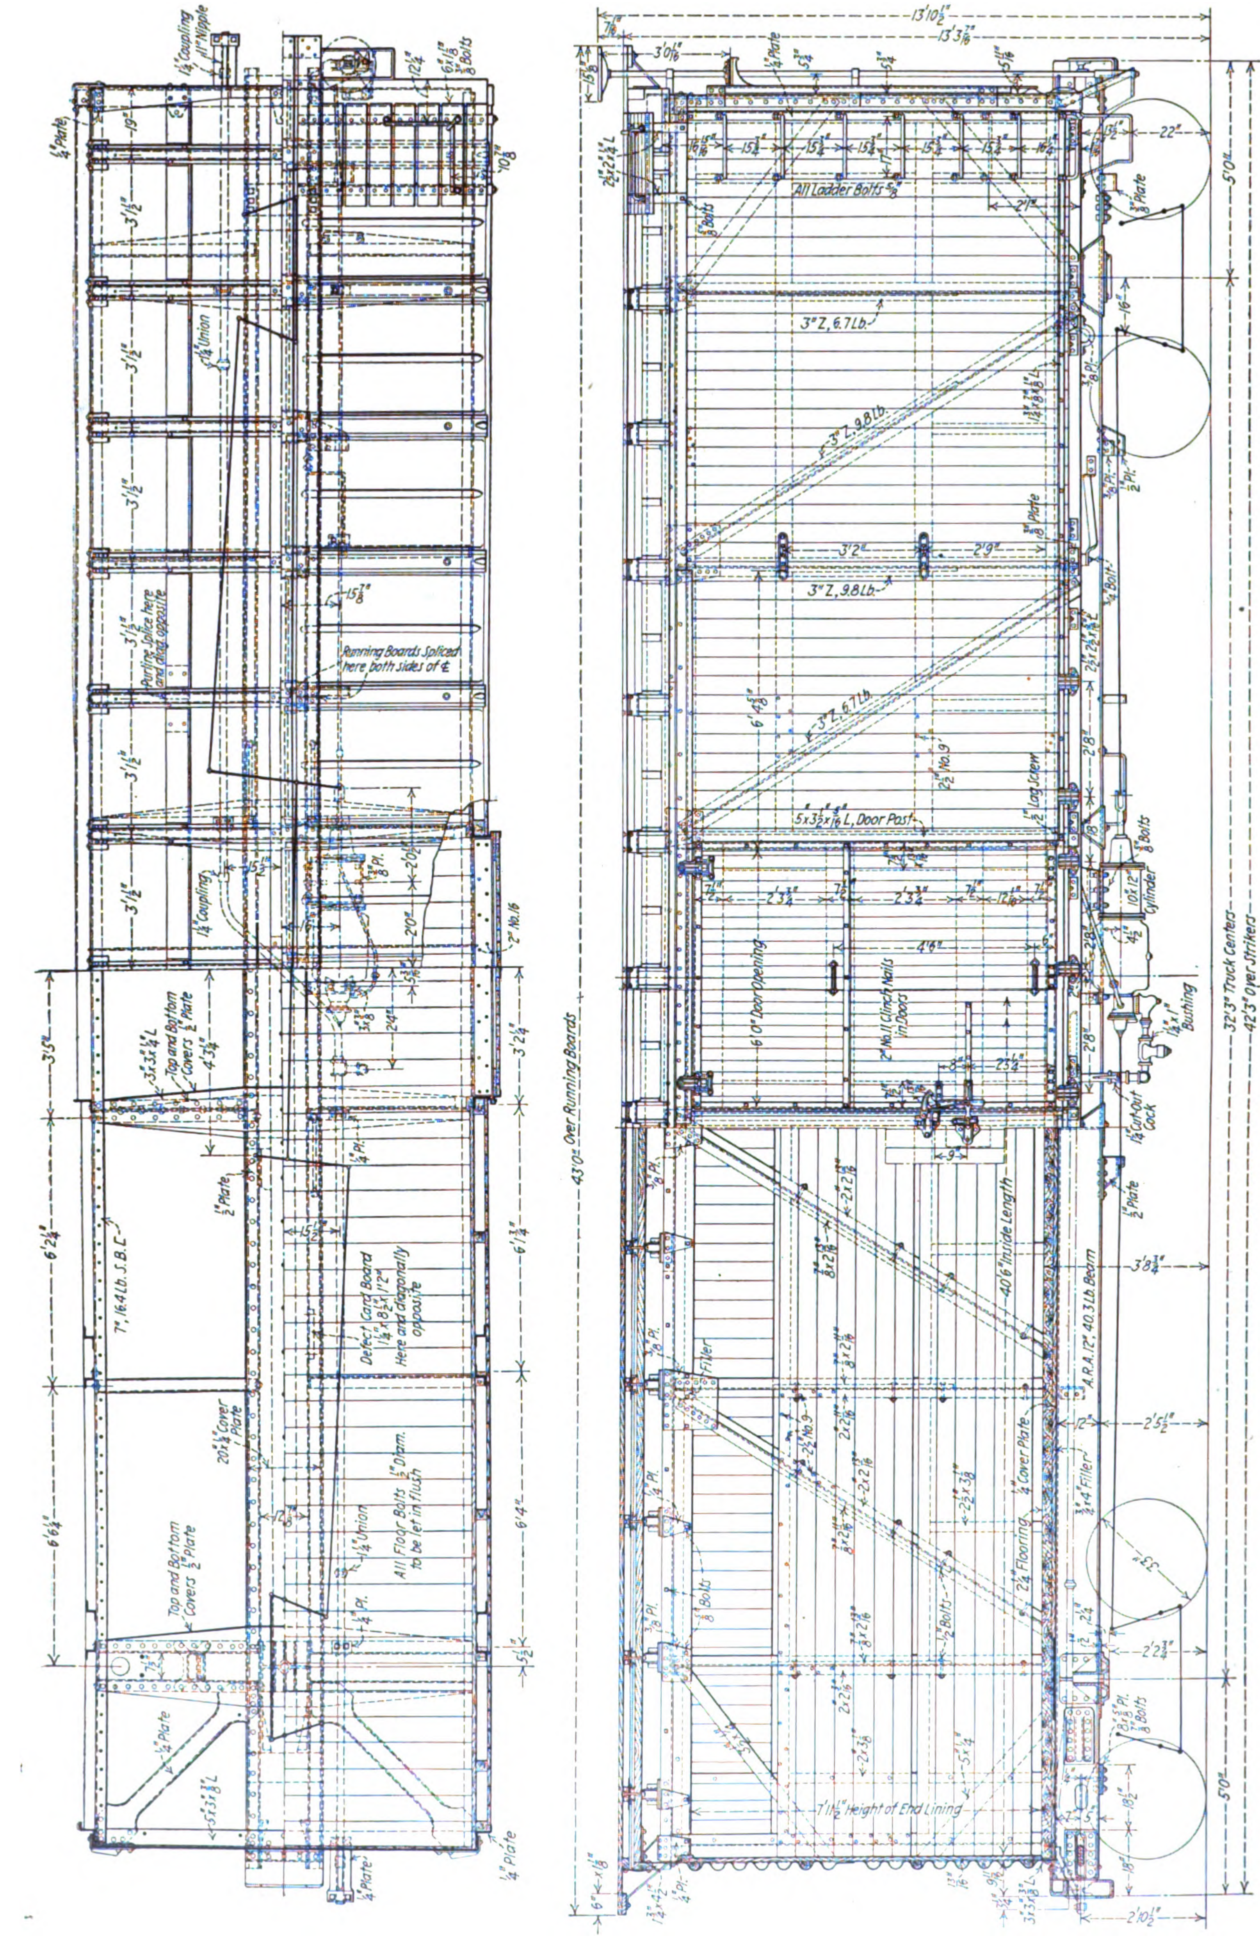
By P. Alquist
Master car builder, D. L. & W., Scranton, Pa.

THE terminal facilities of the railroads serving New York are steadily becoming inadequate to unload quickly the enormous number of cars which enter the metropolitan area every 24 hours. Enlargement of the terminals is restricted by the lack of sufficient ground for expansion. The Delaware, Lackawanna & Western is one of the railroads confronted with this problem at its eastern terminus.



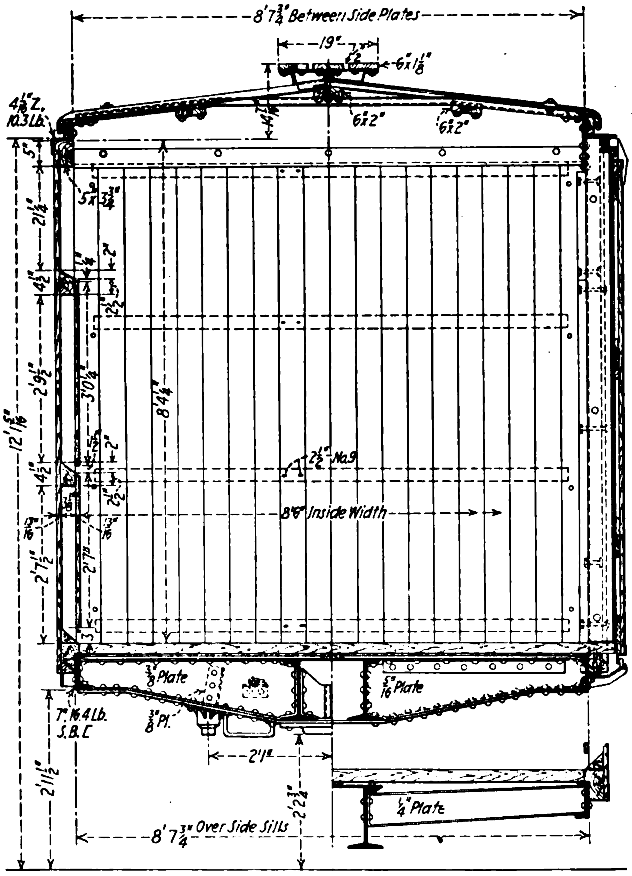
A method of fastening coupler yoke cross key cotters to prevent them from shearing off

One of the methods of combating this problem is to increase the capacity of the cars handling grain, flour, cement, coffee, sugar, etc., without greatly increasing the weight. This was accomplished in the 1,000, 55-ton, steel underframe, double sheathed box cars built by the American Car & Foundry Company, Berwick, Pa., according to A. R. A. specifications. The cars have been in service six months and have proved very satisfactory. These cars were obtained to replace 60,000-lb. capacity equipment retired on account of age, construction and light capacity. The cars dismantled weighed 38,000 lb. The new cars, which will carry 125,000 lb. of grain from the Great Lakes to tidewater, have double the capacity of the old cars, with an increase in weight of only 5,700 lb., or, by increasing the weight of a unit 15 per cent, the carrying capacity was increased 100 per cent. This advantage is particularly noticeable in the room occupied by the trains in the terminal. The capacity of each car unloaded on the grain dock is now equal to two of the older type and it can be unloaded in one-half the time formerly required to unload the same capacity. These cars weigh 1,800 lb. less than the U. S. R. A. 80,000-lb.



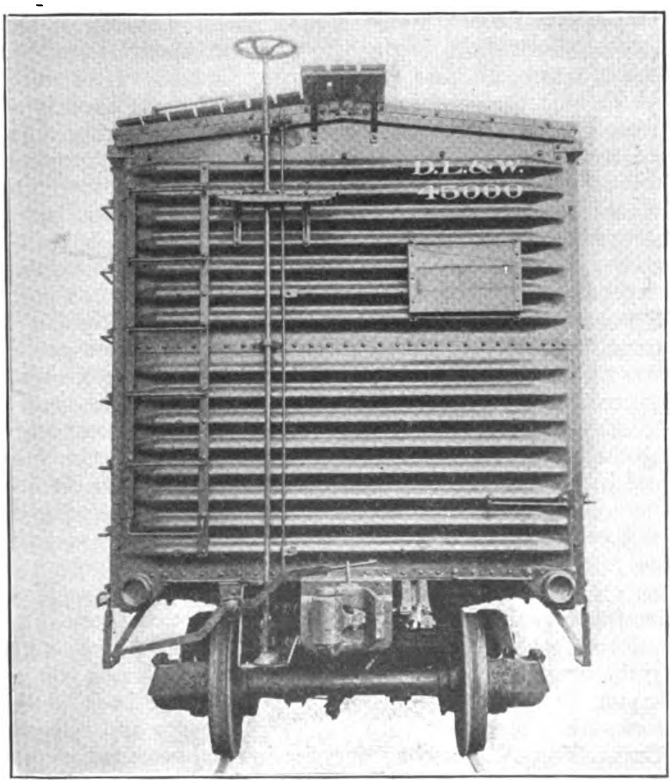
Plan and elevation view of the D. L. & W. double-sheathed 55-ton box car

capacity cars. The switching of our grain trains has been reduced one-half on account of the increased capacity per car. The royalty on patent grain doors and all labor in-



Cross section of D. L. & W. steel frame box car

cident to preparing cars at the loading and unloading points has reduced one-half. Only one-half the number



Murphy corrugated ends are used on these cars

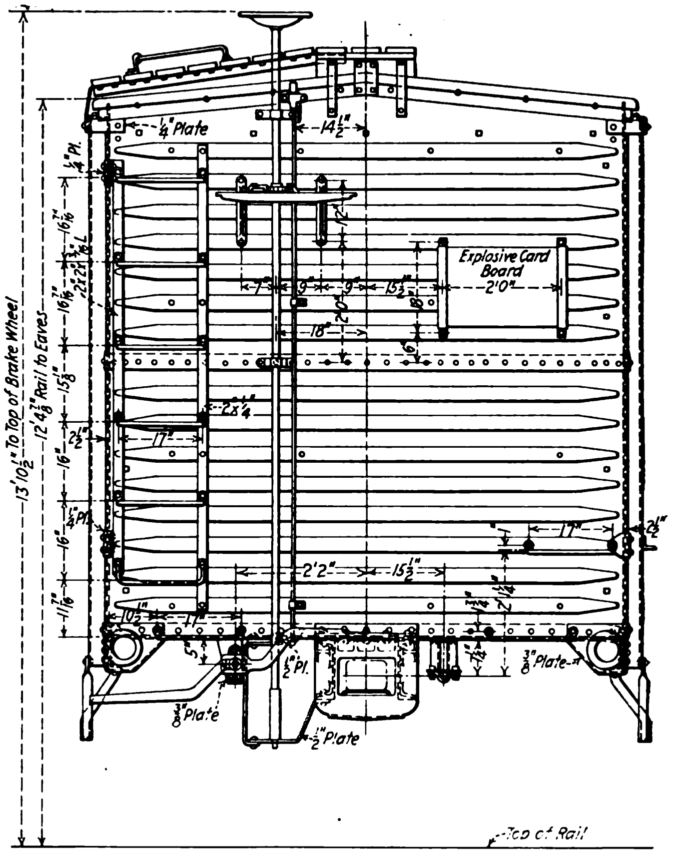
of grain doors have to be returned from tidewater to the Great Lakes in shipping any amount of grain.

General arrangement and details of construction

The underframes are of openhearth steel throughout The center sills consist of two 12-in. A. R. A. standard 40.3-lb. special rolled channels, reinforced by a ¼-in. by 20-in. top cover plate.

The body bolsters are of the built-up design consisting of two ⅜-in. diaphragms, extending from the center to the side sill channel and spread 7½ in. between the webs. They have a steel filler casting between the center sills. These are all connected together and reinforced by ½-in. top and bottom cover plates.

The side sills are of 7-in., 16.4-lb. channels and have angles riveted to the outside faces. The end sills are of 5-in. by 3-in. by ⅜-in. angles and are riveted to the



End view of the D. L. & W. box car showing arrangement of ladder, grab irons, etc.

side sills, diagonal braces and center sills. The body framing consists of 3-in. Z-posts and 3-in. Z-braces riveted to the top plate gusset and side sill.

The cars are equipped with Murphy corrugated steel ends which are made in two sections, the upper section being 3/16 in. and the lower ¼ in. thick, with substantial gussets extending back over the outside sheathing.

The siding is Douglas fir, 13/16-in. thick, dressed on both sides, tongued and grooved. The end and side lining is of the same material, also tongued and grooved, extending from the floor to the top of the car and all secured to 2½-in. by 2-in. fillers bolted to the corrugations of the steel ends. The 2¼-in. thick by 5¼-in. face yellow-pine flooring is tongued and grooved and extends to the outside edge of both end sills. Steel threshhold plates are applied in each door.

The Hutchins dry-lading roof made of No. 16 gage steel is used and is supported by pressed steel carlines.

The latitudinal running boards are of Douglas fir, dressed on one side to 1⅛ in. thick and applied rough side up. The longitudinal running boards are of three planks, 6 in. wide by 1⅛ in. thick, dressed on one side and applied rough side up. They are secured to pressed steel saddles by ⅜-in. carriage bolts.

Single side Camel No. 27 doors are used which provide an opening of 6-ft. They are steel bound, top hung, equipped with Camel combination door stop, lock and door closing and starting device.

The cars are equipped with 55-ton Bettendorf 5-ft. 6-in. wheel base trucks, with U-section cast steel frames. The journal boxes are an integral part of the truck frames, and conform to the A. R. A. standard dimensions for 5½-in. by 10-in. axles. The Barber lateral motion device and Woods tip roller side bearings are incorporated in the truck design. The truck bolsters are of the cast steel type. The ends of each bolster are provided with three rollers of cold rolled steel 2 in. in diameter and 10 in. long. The combination roller seats and spring caps are of drop forged steel. Davis cast steel wheels are used, which reduced the light weight 1,200 lb. per car.

The draft gear is the Cardwell type G-11-AA and the A. R. A. standard Type D coupler with a 6-in. by 8-in. shank is used. The couplers are equipped with 18½-in. pocket Universal cast steel yokes. The uncoupling device is the Carmer type. To prevent the coupler yoke cross key cotters from shearing off, which is so prevalent with the Type D key couplers, the D., L. & W. has designed and patented a key fastening, shown in one of the illustrations, which takes the strain off the cotter. It has four and one-half times greater shearing resistance than the ⅝-in. U bolt used on the A. R. A. cars. This fastening has eliminated cross keys from working out.

The air brake equipment is the Westinghouse quick-action, automatic Schedule K. C. 1012, with K-2 triple valves, 10-20 retaining valves, duplex spring loaded; Creco four-point brake beams with safety supports, with Schafer pressed steel bottom connections and drop forged U-type self-locking hangers are used. All the air brake pins and top brake beam hanger pins are equipped with positive brake pin locks manufactured by the Illinois Corrugated Metal Company. The hand brakes are connected direct to the brake cylinder push rod with a Universal booster introduced in the hand brake rod attachment to develop a pressure equal to the nominal air brake pressure. The Vissering perforated malleable iron brake step board is used.

Report of car inspectors' and foremen's convention

Abstracts of papers on grinding cast iron wheels and prevention of transfers and claims

FOLLOWING are abstracts of the discussions on the papers on lubrication and a progressive system of freight car repairs which were published in the October, 1925, *Railway Mechanical Engineer,* page 627. Abstracts of a number of other papers and discussions presented at the twenty-fourth annual convention of the Chief Interchange Car Inspectors' and Car Foremen's Association of America, which was held at the Hotel Sherman, Chicago, September 22, 23 and 24, are also published in this issue.

Discussion of paper on lubrication

A. H. Herbster (N. Y. C.): The New York Central has a number of dope reclaiming plants and it is surprising the dirt, grit and foreign matter that you get out of the dope that we have not been able to get before, and we certainly agree that the dope is kept in better shape and is better for re-use than it has ever been before. We have found that the waste from the paint and machine shop is not suitable for re-use.

F. W. Trapnell (Kansas City, Mo.): It was stated that in passenger and locomotive equipment, it was necessary to use wool fiber. In freight cars you can use cotton waste of fiber.

M. P. Cole (B. & M.): We are cleaning all the new axles and new journals which we apply, removing all the foreign substances on that journal, applying a little free oil, and making sure that the journal which we apply has a crown bearing. On passenger equipment, one year ago we started to jack all passenger equipment twice a year, in the fall and in the spring. We were obtaining 197,000 miles per hot box, in the passenger service, at that time, and last month we obtained 460,000 miles per hot box.

C. J. Nelson (C. I. I., Chicago): I think one of the first considerations involved in connection with this subject of lubrication, is the use of good material and that means waste, oil, and your bearing surface. It is unfortunate that the selection of the material to be used is not always in the hands of mechanical men. Making a roll too compact is liable to result in an early glaze, and some railroads have had bad results from that practice. One of our worst enemies is the glaze, and it cannot be destroyed without removing the packing from the box. The poor car inspector is to blame for it, but our lubricating expert says "poor oil." The solution is, first class attention and the only way to provide such attention is to arrange more frequent repacking of cars and then get the cars on the repair track so that you can do the work more efficiently.

H. Andrews (N. Y. C.): I was at a session some years ago when you gentlemen were in favor of checking up and inspecting journal bearings once a year, you did well for awhile and then you came to the idea that keeping the cars moving over the railroad was all that was necessary and would accomplish the purpose. If you will go out on the repair tracks and check up after the men whose duties are to properly care for the repacking of journal boxes I am quite sure you will find that if more attention was given to the brasses the cause for many of the hot boxes you are having would be found, and you will come back to this convention next year with a different theory and different ideas. You are not changing the journal bearings, gentlemen, and that is contributing to the cause of the hot boxes.

Discussion on progressive system of freight car repairs

H. Andrews (N. Y. C.): I would like to know if this program is outlined on a day work basis and just what checking up is done.

F. A. Starr (C. & O.): We are working on a day work basis and our production is superior than when we work piece work.

W. P. Elliott (T. R. R. A.): I recall at our last convention we had some discussion on the best way to cut out rivets. At that time I expressed myself as being in favor of the burning out process, but since that time I have changed my mind, I do not believe in the burning out process. I believe that there are rivet busters now on the market far superior to any burning process, that is for rivets ⅝-in. or ¾-in. I believe that we would not find it so satisfactory for rivets larger than ¾-in. The greater part of our work in rebuilding cars is on ⅝-in. rivets and our machine now in use is far superior to the burning process.

It is cheaper than the electric burner and the acetylene torch. It costs 1½ cents to cut out rivets with the burner and with the rivet busters we can do it for one cent.

F. S. Cheadle (R. F. & P.): With a shop program like the C. & O. there always will be a difference of opinion as to the best method of removing rivets, whether by burning or cutting, acetylene or electricity. I can absolutely agree that the burning process used by the C. & O. is superior and cheaper than anything I have come across.

E. G. Chenoweth (C. R. I. & P.): I find from my own experience that you should have a good man to deliver material and have in the organization such conditions in which you can return the material not used to the place from which it comes. In moving the cars the tendency is to deliver more material than is used. The effort we have put forth at this time to get this material back again to our storage place has been gratifying and has helped us a great deal, the fact that good material is strewed around cars and is not used is not only due to the man who delivers the material but due to the effort on the part of the workman that save some of the old material that may be still on the car.

One other thing that I want to bring up is the stripping of cars in order to get the rubbish all on one side of the yard. We have set aside two or three tracks for stripping cars for heavy repairs. The car is then moved onto the repair track and this keeps lots of the rubbish away from our repair track and we can concentrate our efforts for stripping at other points. We are working general piece work and I have found that we use about 10 men to strip cars on an average. Piece-work changes with the education of man on repairs, and I was surprised at the statement made today that they found they could get the work out faster in day-work than in piece-work. This has been entirely different in our experience in the past few years, and we have some interesting figures that have been worked up along this line.

We cannot, in a general repair plant, order material so far ahead as outlined in the paper today. We have to adjust ourselves to what is coming in and to the equipment that we may be required to handle. Complications may come up, therefore we have to work very close to the stores department, keeping them advised in advance as to what will be required. In doing this sometimes we have to wait, holding up equipment for a few days waiting for material to come, but it is found by most railroads that this is satisfactory, instead of getting a large amount of material in stock that possibly will not be used for some time.

In routing of cars and delivering material our foremen make out the list when the car comes onto the repair tracks. The foreman who has supervision over making repairs to the cars has nothing to do with the stripping but as soon as cars come onto the repair track he puts out slips for men to deliver material to the particular car. This class of material lies alongside of the track about where we expect to do this class of repairs. We have tried out both moving the men and moving the cars and as near as we can find by making a careful study there is not much advantage one over the other, but I personally would recommend moving the cars instead of the men due to the fact that your material can be put on the side of the track where you expect to use it.

Another thing that comes up in classified work which I was in hopes would come up here today is in arranging a piece work schedule for classified work. That is one of the hardest things to do, due to the fact that a man becomes expert in one class of work and naturally his pay begins to go up. In the beginning he started out satisfactory, this shows that when you classify work on piece work it means pay begins to go up as the man becomes expert in the work to which he is assigned. In this connection I have tried another scheme. We have four different divisions in our shop, of from 50 to 60 men. Each foreman in that department doing the same class of work. Instead of having an expert on each of these divisions or in each part of shop, we have men who do this all over the yard, for instance, like underframes or setting of the roof, etc. In a large yard this would work out all right, but as said before you run into the same thing as piece work; a man becomes expert and you may have to consider schedules again and as many of you know it is not a good thing to consider decreasing piece work prices.

Mr. Elliott: I want to say that I agree with Mr. Chenoweth and disagree with Mr. Starr. I don't think he meant what he said when he said he was getting more work on a day work basis than on piece work.

Mr. Starr: I do not say we are getting more work, I did say that we consider that we are getting more satisfactory results. The contention that piece work makes greater experts of men has not been proven in practice on railroads. We are doing equally as well as under the day work system and are doing it with less supervision, and our men become experts and strive to surpass each other in the quality of their work which must not be sacrificed for quantity.

I do not by any means wish to convey the idea that we have on the ground enough material to last through the year, but we do not start on the program until sufficient material is on hand to carry on the work until other material is received. We keep the stores and purchasing departments advised as to what we expect to do during the year and the material required to carry through the schedule, outlining to them just how, when, and in what quantities material should be delivered to us during the year.

The moving of the cars to the men as compared with moving the men to the cars has not been satisfactorily threshed out so far as railroad shops are concerned, where the shop is not equipped with overhead cranes, especially where cars must be moved by switch engine or by being pinched. When moving the cars to the men quite often delay results on account of gangs or men waiting until the entire track is moved. If you can arrange the schedule so that each cut remains on the track until the close of the day and all switching done after working hours, this surely would be satisfactory, otherwise your men and gangs must wait for cars to be moved.

In removing the arch bars and annealing them any crack and defect is easily detected. When you turn out a

car every piece ought to last until it comes back again for general repairs. Regarding the box and column bolts, if the car is undergoing class repairs and the bolsters are replaced with new, the same procedure is carried out with the column bolts.

The trucks are the most important part of a car, and if you get trucks in good condition you will keep the car off the repair tracks, for about 90 per cent of the defects are due to faulty trucks.

With reference to using labor for repairing furnaces, we use a car repairer helper and there is nothing in our agreement that prevents us from doing so, however, any pipe work must be done by pipe men. What I meant was this, they fill the furnace with fire brick and fire clay so that the oil and gas which we have will heat the rivets.

Mr. Andrews: Is it necessary to anneal the arch bars? In case the box bolts and column bolts are in condition that they might be left in the car, would it be necessary to anneal them?

Mr. Starr: I do not see any objection to annealing arch bars if they are in condition to go back in the car. I do not know where anything could be gained or lost by annealing the bolts, if a bolt is cracked under the head it could be detected easily.

Grinding cast iron wheels

By W. M. Allison

Traveling car foreman, D. T. & I., *Detroit, Mich.*

In the 1924 report of the Wheel Committee of American Railway Association it was strongly recommended that the practice of grinding slid flat cast iron wheels should be adopted as a standard practice of the Association. It was also recommended that the Arbitration Committee give due consideration to the practice and see that changes were made in the rules giving recognition to the ground wheel as a proper wheel for application to foreign cars.

The Detroit, Toledo & Ironton, together with a number of other railroads in the country, have purchased wheel grinding machines and have made extensive tests as to the safety as well as the practical and economical phase of the use of such wheels and it has been proved beyond a doubt that this is an item which would be a great saving to all railroads and can be done successfully without damaging the strength of the wheel in any particular, in fact greatly increases the life of a second hand wheel.

The practice of regrinding cast iron wheels has been in effect on the D. T. & I. for the past two years and before the grinding machine was put in every conceivable test was made from a practical as well as a safety standpoint.

Various manufacturing plants were visited where cast iron wheels were made and wheels examined which had been broken for test purposes. In no case was the chill less than 5/8 in. in depth, and as the A. R. A. has a minimum of 1/2 in. on new cast iron wheels flat spots of from 2 1/2 to 3 1/2 in. can be easily ground out without affecting the chill in any manner, in fact some of the roads grinding wheels claim that even 4 and 4 1/2-in. flat spots can be ground out.

In selecting wheels for grinding we are governed by the condition of the flange, tread and size of slid flat spot, choosing only such wheels that will retain the proper flange height and thickness, as well as proper diameter and hardness.

In our practice of regrinding wheels, owing to the small size of flat spots existing on those re-ground, we have never had to take off more than 1/16 in. to 3/32 in. to clear off the outside defect. The wheels are then given the Brinell hardness test which will show whether or not the wheel is affected by the process and it was found that the Brinell test shows the wheel slightly harder in most cases after grinding than it was before; however, in some few cases the Brinell reading is a little lower as will be shown by the following figures on 10 wheels on which the test was made.

Tests of chilled cast iron wheels

Wheel No.	Brinell hardness: Before grinding	After grinding
1	358	403
2	339	381
3	387	363
4	358	405
5	358	392
6	358	429
7	352	423
8	363	392
9	363	411
10	363	360

About two years ago the D. T. & I. had a pair of cast iron wheels cast in 1911 with a slid flat spot 2 1/2 in. which we re-ground and placed under one of our cars. These wheels have been in service since that date. We recently made an inspection of this pair of wheels, which incidentally are still traveling under the same car, and after two years of continuous service are still in good shape.

The machine which we use grinds both wheels at the same time and not only takes out the flat spots but takes out all imperfections or rough spots in the thread of the wheel, making them perfectly round, therefore making a perfect rolling surface which no doubt will in a manner prevent slid wheels and insure the smooth running of trucks.

We have had representatives from various railroads visit our plant and see the machine in operation and we believe that they are thoroughly convinced that this practice not only gives a second hand wheel but gives a far better wheel than the average run of second hand wheels; in fact, we believe that the average re-ground cast iron wheel is as good as a new cast iron wheel as far as the length of life is concerned.

Owing to the great saving which can be made by all railroads by adopting this practice, we believe that the members of this Association should make a careful study of the practice and recommend the adoption of such on their respective lines.

In regard to the charges for such work owing to the cost of installation of the machine required, provision should be made whereby the roads would be allowed to charge a reasonable amount for the reconditioning of such wheel and we understand that this phase is being considered by the Arbitration Committee at this time.

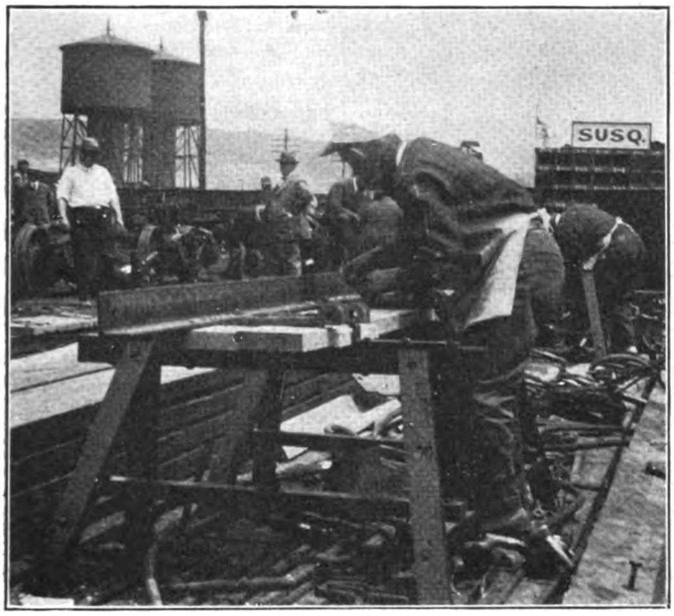
The object of bringing this matter to the attention of this Association is to get every man interested and educated to the great saving which can be effected.

A convenient horse for the wood worker

THERE are many jobs around a wood mill, such as the assembling of doors for wooden hopper cars, doors for refrigerator car hatches, etc., that require the boards to be drawn tightly together for the application of strap hinges and metal braces. Many wood workers use extension clamps for this job. A quicker and simpler method of doing this kind of work is by the use of the horse shown in the illustration, which shows one of the wood workers on the Susquehanna division team, winners of the car building contest held by the Delaware & Hudson

at Carbondale, Pa., May 21, 1925, assembling a bottom drop door for a composite hopper car.

Two pieces of wrought iron bar about ½ in. by 1¼ in., each having one end turned up at 90 deg. to a height of about 1½ in., are bolted to the top of the horse. The turned up ends serve as bearing surfaces for the wedges.



Assembling a bottom hopper door—The boards are drawn together by wedging them between two lugs on each of the horses

The boards for door are laid on the horses, as shown in the illustration, between the two wrought iron lugs. After the boards have been properly lined up, the wood workers drive a wedge between the lug and the edge of the door, drawing the boards together. He then proceeds to apply the bottom angle and hinges.

Educating car inspectors on the C. & E. I.

By R. E. May

District car foreman, Chicago & Eastern Illinois, Salem, Ill.

THE following outlines for the most part the method of educating car inspectors on the Illinois-St. Louis division of the Chicago & Eastern Illinois, which is quite similar to the method used over the entire system. On this division there are four car shops at intervals, each having three shifts of car inspectors and oilers employed in the train yards. At each of 21 other outside points from one to three car inspectors are employed.

Each month a list of 20 questions is compiled on A. R. A. rules, loading rules, safety appliance rules and Bureau of Explosives rules (the questionnaire effective March 1 was extended to include billing rules), these questions being sent to each inspector, foreman, and A. R. A. clerk on the division with instructions to answer them, give the rule reference, and mail them back to the district car foreman's office not later than the third of each month. There they are gone over carefully by the foreman and graded and a record kept of each man's grade. Correct answers, attached to each list of questions, are returned to the men, a typical set of questions and answers being included in this article.

During the month following, educational meetings are held at various points on the division as follows: Salem yard, Villa Grove yard, Mitchell yard, West Frankfort yard and Cypress. In this manner practically all car inspectors are enabled to attend a meeting at which the questions, used as a subject, are analyzed and discussed so that each man gets a thorough understanding of them. In addition, all inspectors are asked to bring up any questions pertaining to interchange, loading, billing, etc., of which they are in doubt, and these are discussed and a decision made. The office in which the meeting is held is supplied with a blackboard 16 in. by 48 in., lined to represent a billing repair card. During the month preceding the meeting a number of errors found on original records of repairs made by inspectors during that period are sorted from the files, and brought to the attention of those in attendance at the meeting.

First, the record of repairs is placed on the blackboard as improperly written by the inspector. The men are then asked to take exceptions, and usually one man is asked to come to the board and write the records properly. Thus all concerned may profit by the errors of others, knowing at future times how records of repairs covering certain limits, should be written. If any questions come up at the meeting which cannot be answered they are referred in writing to the A. R. A. committee of the Chicago Car Foremen's Association.

To test the thoroughness with which the inspectors' duties are understood and put into practice, periodical checks are made on original records and repair cards, the mistakes found being called to the attention of the inspectors responsible so that in the future they will not be likely to make the same mistakes. This plan has been successful in promoting interest and also familiarizes the inspectors with the rules, for, while they are looking up the answer to one question, they are reading the answers to several others. This plan can also be extended to cover instruction in air brakes, steam heat and various other subjects of vital importance to the successful railroad operation.

The men at and in the vicinity of Salem yard have recently organized, elected their officers in the regular manner, and assessed a small sum for dues. The money obtained in the form of dues is used in providing a meal, cigars, cigarettes, etc., for all who can attend, thereby enabling the men to enjoy a social time and get better acquainted with each other. The secretary draws up the minutes of each meeting, outlining all decisions which have been made on various questions, also outlining in the proper manner repair cards or records which have been discussed. These minutes are briefed as much as possible, mimeographed, and a copy sent to all concerned on the division. The minutes of each meeting held at Salem yard furnish additional material for discussion by inspectors who attend the meetings at other terminals. Thus far this system has been very successful and apparently beneficial to all concerned. By keeping a record of the grades, we know the men who need the most training and in the meetings these men are encouraged to ask questions and are given particular attention. In every instance they are just as eager to learn as we are to teach them.

Typical questionnaire submitted to C. & E. I. car inspectors February 1, 1925

Name, John Doe. Occupation, Car Inspector. Station, Salem Yard.
February 1, 1925.

Q. 1—Is equipment stenciling required on cars for certain details such as Type D couplers, K-1 or K-2 triple valves, when the stenciled date built definitely establishes the standard of car?..............

Q. 2—Who is responsible for defects caused by sudden stop due to emergency application of air brakes or bursting of air hose?............

Q. ?—Is it necessary to stencil cars equipped with D type coupler in order to protect them against substitution of the old style M.C.B. coupler?..............

Q. 4—If you received in interchange a car that was being shipped home, loaded on another, on special authority of the owners, for repairs to owners' defects, would you issue defect card for missing material and the labor necessary to repair same?..............
Q. 5—Is it permissible to paint over inflammable placards on empty tank cars when they cannot be readily removed by scraping or soaking?..............
Q. 6—Can lading be placed on top of box or stock cars?..............
Q. 7—What should be done to permit placing load on top of sides on drop end gondolas?..............
Q. 8—Is it permissible to use wooden flat cars having only two truss rods for twin or triple loads?..............
Q. 9—What should be done when necessary to make the width of lading less than width of car on account of long overhanging, or distance between bearing pieces?..............
Q. 10—How many pairs of stakes are required on single overhanging loads, on carrying car; state location? (piling, logs, telephone poles, etc.)..............
Q. 11—What kind of a hand brake must a freight car be equipped with to comply with the law?..............
Q. 12—What is the minimum diameter for side hand holds?..............
Q. 13—Is the handle of an uncoupling lever which is 14 in. from side of a car (freight) a violation of the law?..............
Q. 14—What kind of a car must be equipped with vertical end hand holds?..............
Q. 15—When single uncoupling lever is used, on which side of the end of the car must it be located?..............
Q. 16—Should packages containing inflammable liquids be entirely filled? ....
Q. 17—How long must charcoal which has been burned in pits or kilns stand in open kilns, or air, before being loaded in a freight car?..............
Q. 18—Is it necessary to place caution signs on track when unloading tank cars on railroad property?..............
Q. 19—When dangerous articles requiring the red label are shipped in the same outside package with dangerous articles requiring yellow or white labels, how should package be labeled?..............
Q. 20—How should interior packages containing corrosive liquids be packed?..............

The above questions are based on the A. R. A. rules, loading rules, Safety Appliance Laws, and Bureau of Explosives regulations. They should be answered by all foremen and inspectors at outside points and terminals, including all men working in train yards, and sent to this office before February 1, if possible, and not later than February 3. All answers should be made as brief as possible and where possible, show rule reference or page number in rule book where answer is found. These questions and their answers will be discussed at the educational meeting to be held in the office of the car foreman at Salem yard, Thursday evening, February 19, 1925, at 6:30 p. m.

R. E. May,
Dist. Car Foreman.

Answers to monthly questionnaire dated February 1, 1925

A. 1—No. A. R. A. Rule 17, interpretation 17
A. 2—Owner's responsibility except as otherwise provided for in Rule 32. Emergency application from rear of train, however, is unfair usage. A. R. A. Rule 32, interpretation 5.
A. 3—Yes. A. R. A. rule 17, interpretation 2.
A. 4—No.
A. 5—Yes. A. R. A. Rule 36, interpretation 6.
A. 6—No. Loading Rule 11.
A. 7—Corner stakes must be suitably reinforced. Loading Rule 9, paragraph F.
A. 8—No. Loading Rule 20, paragraph B.
A. 9—Filling pieces must be placed between the stakes and lading, and securely fastened to inside of stakes. Loading Rule 119.
A. 10—Five pairs. Three pairs should be placed near the bolster at the overhanging end, and two pairs at the opposite end. Loading Rule 132.
A. 11—An efficient hand brake.
A. 12—5/8 in.
A. 13—Yes.
A. 14—Full width platform end sill car.
A. 15—Left side.
A. 16—No. Paragraph 405, page 47, Bur. of Expl. Regulations.
A. 17—Not less than 24 hours. Paragraph 463, page 56, Bur. of Expl. Regulations.
A. 18—Yes. Paragraph 1050, page 110, Bur. of Expl. Regulations.
A. 19—Red label only. Paragraph 309 (f), page 37, Bur. of Expl. Regulations.
A. 20—With the filling holes up. Paragraph 522, page 63, Bureau of Expl. Regulations.

"Carlisle, the gateway to Scotland," a poster printed in color by the London Midland & Scottish

Dolly bar for bucking up rivets

ONE of the devices used in the recent car building contest held at Carbondale, Pa., May 21, 1925, by the car department of the Delaware & Hudson, which attracted considerable attention, was a lever dolly bar used by a riveter on the Colonie team. As shown in the illustration, the riveter is able to hold a rivet and buck it up at the same time. This eliminates the services of a second man to perform the work of bucking up.

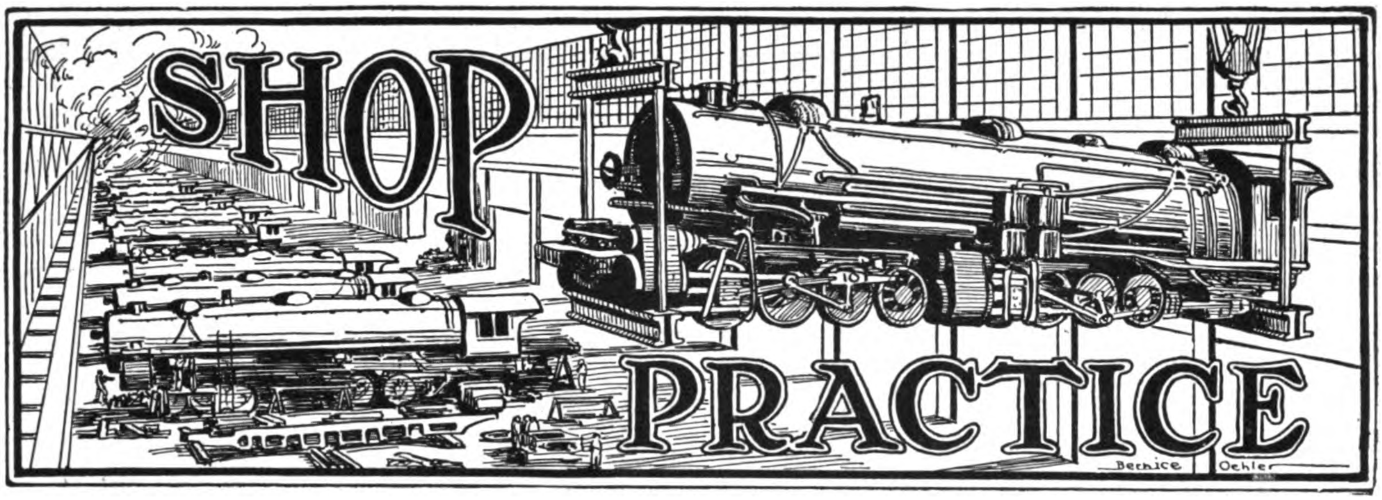
The device is made of steel bar about ½ in. by 1½ in.

Steel worker driving a rivet and using the lever dolly bar for bucking up

One end is constructed to hook under the flange of the center sill channel and the opposite end provides trunnion bearings for a dolly lever on the outer end of which the riveter places his foot. The pressing down of this lever forces the rivet up tight into the hole and at the same time brings the top cover plate down tight against the flange of the center sill channel.

THE CHINESE GOVERNMENT railways have adopted uniform accounting for their shops. The charges have been divided into two categories, power and general. In shops where absence of electric or steam meters prevents accurate distribution of power costs, machines are to be given a horsepower rating and the use of such machines will be timed in the same manner as time is kept for labor. General charges and power charges are first debited to respective suspense accounts, which accounts are cleared by fixed rates per machine horsepower hour and fixed percentages on labor costs as jobs are completed. These rates and percentages are to be revised as necessary in order to maintain balances at a minimum, due allowance being made for seasonal fluctuations.

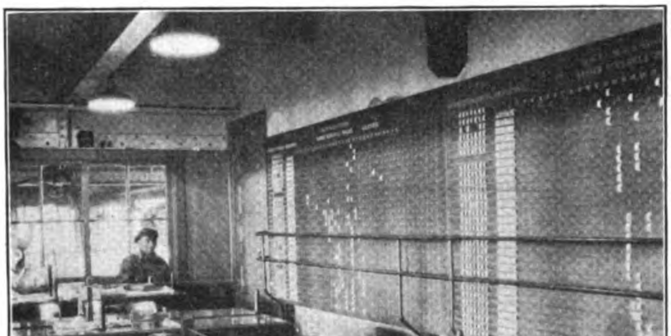
Foundry costs are treated similarly, the foundry suspense account being cleared as good castings are delivered at a uniform rate per pound or per kilogram. Articles manufactured for stock or for other departments may thus be priced on delivery, thus avoiding one of the most serious difficulties in Chinese material accounting. Due to the limited education of foremen in shops, assignment of workmen to jobs is to be accomplished by means of boards upon which the job number is chalked, under which workmen's number checks are hung. Timekeepers will record these assignments four times daily, broken time to be estimated in consultation with foremen. An attendance record is made out by a similar process at the entrance gate and the two records, one in the shop and the other at the gate, are to be compared daily.



Some impressions of Burnham locomotive shop

Improved morale evident at new D. & R. G. W. shop—Effective routing and material delivery systems—Time saving shop devices

THE new locomotive shop of the Denver & Rio Grande Western, located at Burnham on the outskirts of Denver, Colo., and described on page 491 of the August, 1924, *Railway Mechanical Engineer*, holds much of interest in the way of modern equipment and effective shop methods, developed since it was placed



Interior view of formen's office showing glass top desks and master schedule board with guard rail on the wall

in operation about 15 months ago. In common with most railroad shops during this period, Burnham has not been forced to anywhere near its maximum productive capacity and consequently a comparison of the locomotive output, before and after the erection of the new facilities, would hardly give a fair measure of their value. In spite of this fact, however, the output per man employed has increased substantially. The record shows that in 1923 the average number of men working in the locomotive department at Burnham was 521, the average output being eight heavy repair locomotives a month. For the first nine months of 1925 the average force employed in the locomotive department was 384 men, or a decrease of 26 per cent, the average output dropping to seven locomotives a month, or a decrease of only 12½ per cent. The 1925 locomotives received on the whole appreciably heavier repairs than those put through the shop in 1923.

Aside from the question of output, the visitor at Burnham shop will probably be most interested and impressed by its excellent design and construction, fine day- and night-lighting facilities, and the full complement of modern machinery, described in detail in the preceding article in the *Railway Mechanical Engineer*. Other points which may strike the attention are the exceptional cleanliness and order apparent in all departments of the shop, the high standard of morale evident among the men, the effective shop schedule or method of routing locomotives through the shop, and last, but by no means least, the shop delivery system which gets material from the stores department where needed, when needed and with the least possible delay.

While the importance of order and cleanliness may sometimes be over-emphasized, railroad shops are not commonly subject to that criticism. More often they are dirty and congested, even with an average output, and when a sudden demand comes for power and the shop is filled with locomotives, this congested condition becomes a serious handicap in any attempt to obtain the desired output. Doubtless Burnham shop will present a different appearance when every pit in the erecting shop is occupied by a locomotive undergoing repairs, and various parts of the machinery, boiler and accessories are scattered throughout the shop. The present orderly handling of the work, however, indicates that when the rush comes, Burnham shop will be in a position to handle

it with a minimum of confusion and lost motion. An important factor in keeping the shop clean is the "Clean Shop Banner" awarded weekly to the department which is in the best condition as regards order and cleanliness. This banner is highly prized and provides a constant incentive for each department to do better than its neighbor in the matter of keeping cleaned up and picked up.

Morale—activities of the employees' organizations

A high standard of morale is evident among the employees at Burnham shop and the friendly spirit of co-operation which exists between the supervisory officers and men means much in the way of better working conditions and more efficient shop operation. It may not be amiss to trace the development of this morale and mention some of the means used to foster it.

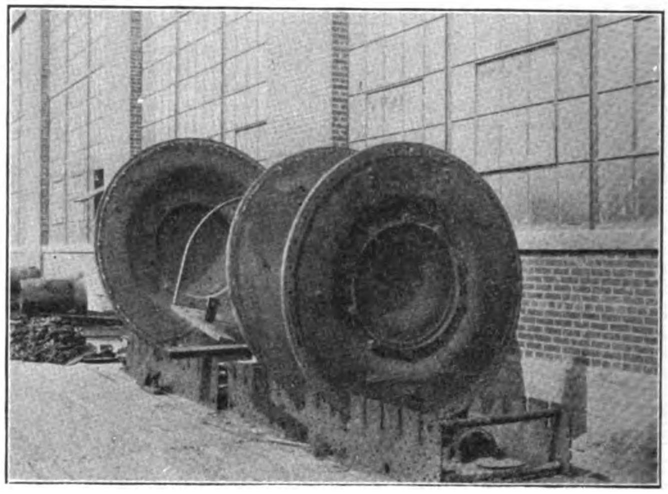
In the fall of 1922 the majority of the foremen at the Burnham shops of the Denver & Rio Grande Western were men who had been with the road a number of years and these, with a few of the older experienced men who acted as instructors, set the pace and standards of work for the new men as employed. Ample supervision was furnished to insure that the work would proceed in an orderly and efficient manner.

Local and system shop organizations were effected, to which the foremen gave their support, as it was quickly determined that with such organizations the foremen were able to direct operations efficiently and gain the interest of the men in producing desirable results.

The men, employed on probation, were naturally anxious to demonstrate their ability. A graduated scale of pay, based on ability, was put into effect with provision for an increase in rate when justified. Under this arrangement helpers are advanced to craftsmen. As there are two shops, one at Burnham and another at Salt Lake, identical in design and practically so in equipment, competition and friendly rivalry is stimulated on similar jobs and classes of equipment between the two shops. The men are interested in the superiority of their shops to the same extent that the supervisors are.

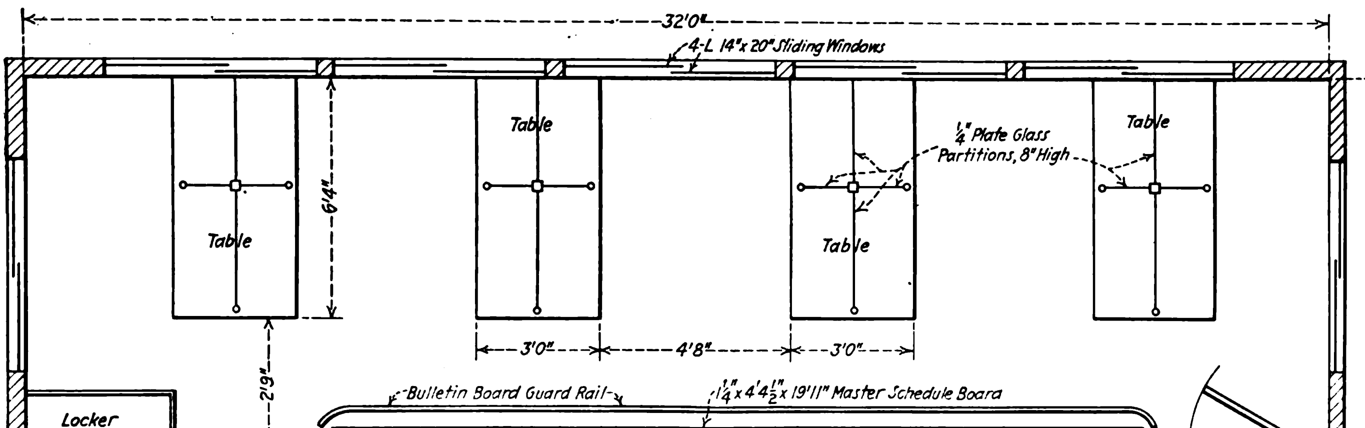
The terms of agreement between the Denver & Rio Grande Western and the mechanical department employees are given a fair interpretation and in cases of doubt are decided in favor of the men. In addition to the new shop buildings with their good heating, lighting and sanitary facilities, every effort is made to maintain desirable working conditions. Heavy manual labor is largely eliminated by the crane and hoist facilities with power tractors and trailers for the delivery system. In assigning men to work, consideration is given to their physical ability and so far as possible men are given work for which they have an aptitude and liking.

Suggestions made by the men are considered by the supervisory board and when adopted are put into service and credited to the originators. If used at other points, a drawing is made and credit given thereon. Grievances are taken up by the shop committee with the department foreman, the general foreman, or the general mechanical superintendent, if necessary, prompt action being taken to adjust any grievances found to be justified.



These racks save space in storing smokebox fronts

One of the most important activities of the employees' organizations is that of the Scenic Line Service Club at each division point, composed of employees and officials of all departments. This club helps cultivate better acquaintance of the members and furnishes an opportunity for talks by employees and officers on any subject pertinent to the interest of the company and employees.



All department foremen have desks in the centrally located general foreman's office at Burnham locomotive shop

A safety committee composed of representatives of all the shop departments meets monthly to consider all suggestions made regarding methods of eliminating unsafe practices and in this manner safeguarding the workmen. To take care of minor injuries and afford first aid in serious cases, an emergency hospital is located conveniently on the shop premises and contains a full complement of sanitary equipment. The rules require that every accident, no matter how minor, providing it involves a break in the skin, be reported in order that the wound may be properly

dressed. A mutual organization provides medical, surgical and hospital service for a small monthly fee.

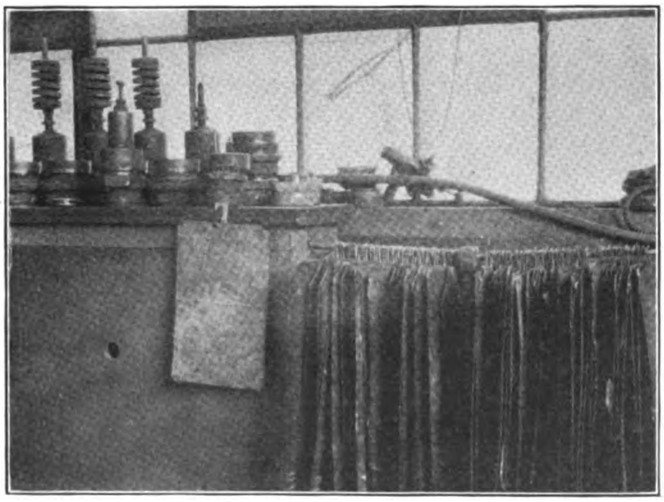
An important feature of the organization work is the stimulation of better acquaintance through various social affairs. The shop band, composed of shop and office employees, furnishes music at meetings, dances and picnics. The dances are managed by the men and held several times during the year. The picnics are annual affairs on each division, for which the transportation is

A departmental schedule board and telephone for ordering material and inter-shop communication

furnished by the company. In addition, inter-shop ball games are played between teams at different points.

The company magazine also is an important factor in encouraging loyalty to the company, containing as it does contributions from all classes of employees on any subject of interest, together with personals, special educational articles and records of accomplishments. There is also a crafts magazine published by the men.

The company encourages relief activities, a special



A convenient blue print rack in the brass room

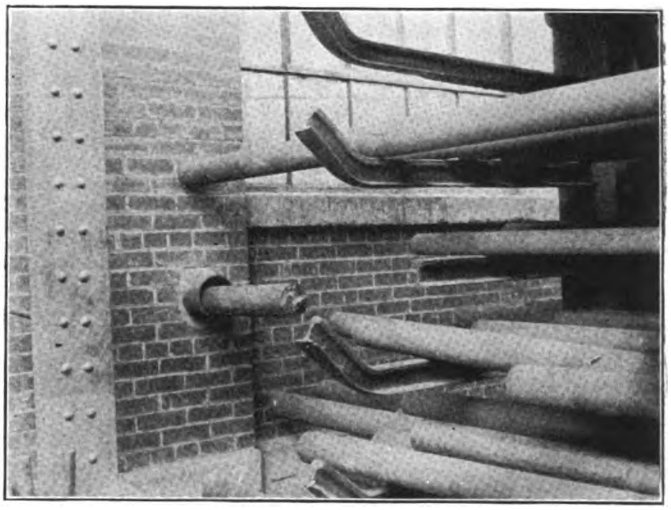
representative investigating needy cases and arranging relief through organized agencies. The pension system provides an annuity for employees reaching the retirement age.

Shop schedule simple and effective

The shop scheduling system which has been developed at Burnham shops is based on the system installed at the Silvis shops of the Rock Island and previously described at some length in these columns. Certain changes have been adopted, however, which seemed advisable to adapt it to local operations.

A master board is located in the general foreman's office, the engine numbers and dates being transferred to departmental schedule boards as required. When a locomotive enters the shop the general foreman sets the date for boiler test and engine wheeled, the schedule clerk then setting all the other dates.

The general foremen's office is also a general office for all department foremen in the plant, with a desk for each one as shown in the floor plan drawing. A meeting is held during every noon hour and a check made of the master schedule board with particular reference to any delays indicated by red tags. With all of the foremen present the cause of the delay can be quickly located and steps provided to take care of the matter. The arrangement of the foremen's office has proved very efficient. It forms a common center where they are all available to each other except during working hours. They are much less inclined to spend time in the office than was the practice when each had an office in his own particular section of the shop. The entire office is visible from the machine and erecting floors so that a man can readily be located



Bar stock for the turret lathes passes directly from the rugged storage racks through a hole in the shop wall to the machines with minimum handling

if he is in the office. At the same time, anybody in the office has a good view of the locomotive shop building.

With the work closely subdivided on the departmental board, each foreman watches to see that the work is delivered to him on time in order that he may get the full benefit of his allowance of time. On this account each man voluntarily traces on the department which handles the work ahead of his. There is no chance to "pass the buck" and fictitious alibis are easily exploded.

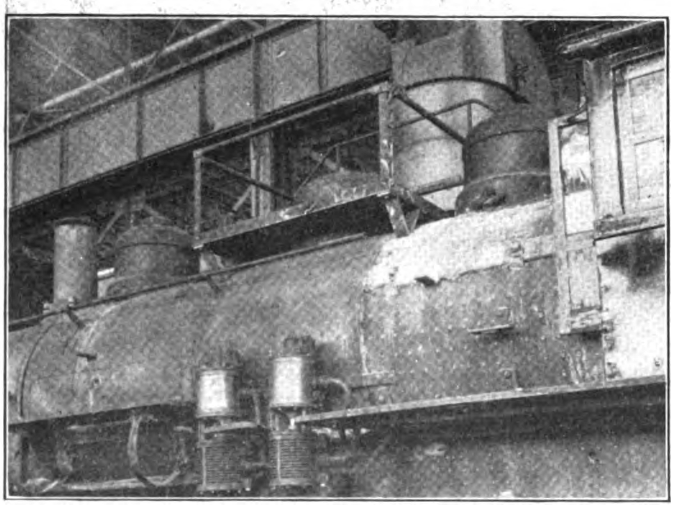
A four o'clock report of material delays, showing the locomotive or shop order number, kind of material, amount, pattern number and date ordered, has been developed which eliminates much waiting for material. It furnishes the shop with a quick record of the material situation, and the division storekeeper is reminded daily of the shop needs. The copy sent the mechanical engineer is checked by him and the general storekeeper in order to straighten out any weak points in the material supply situation. This also provides for furnishing material from other storehouses if available. A marked improvement has resulted in the material situation.

Material is not entered on the four o'clock report more

than once. In other words, if rivets are out of stock for three days the only four o'clock report on which this material shows is one made out on the first day the shortage was noted. The schedule man, before turning in the four o'clock report, checks it with the general foreman who notes thereon if any different arrangement has been made on account of the material being out of stock. In other words, if a casting is ordered and found to be out of stock and the shop makes a forging to do the work in order to keep the engine up to schedule, the general foreman notes this fact on the report. This shows the stores department that it is not necessary to order this casting specially for this engine even though it is out of stock. The stores department shows under the heading, "For store supply," the status of items reported out of stock, giving as nearly as possible the expected date of delivery. This information is entered on the report at once and the original copy returned to the general foreman the same day. The general foreman then goes over the report with other foremen interested so that everyone concerned is acquainted with the situation.

Prompt material delivery

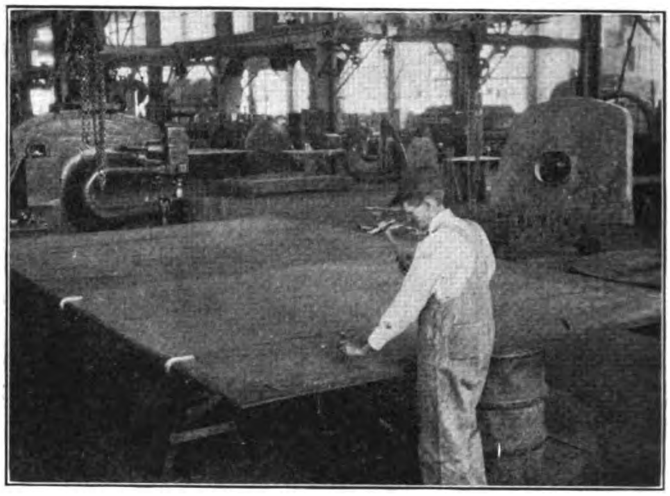
One of the important factors in the success of the Burnham shop operation is the arrangement made for prompt and efficient handling of material from the stores department to the various shop departments as required. In accordance with a practice which has come to be quite common in modern shops, the various steel columns or stations throughout the shop are marked with a combination of letters and numbers by means of which foremen can designate where they want material from the stores department left. At Burnham, however, the "pick-up system," or customary practice of leaving material orders at the various stations to be picked up and subsequently filled by a stores department material trucker on his regular rounds, has been discarded to the extent that orders are transmitted verbally. Telephones



Portable steam dome platform which facilitates throttle work and promotes safety

provided in each of the important shop departments enable the foreman or other authorized person to have immediate communication direct with a stores department switchboard devoted exclusively to shop delivery and attended by an operator who is an experienced stock man. Orders from all parts of the shop, therefore, come to this one switchboard and the operator either knows or can find out immediately whether the material requested is available and if not whether substitute material can be provided. The prompt transmittal of this information to the foreman over the telephone not only saves a great amount of time spent in writing orders for material not in stock, as well as many unnecessary trips between the shop and stores department but materially speeds up shop operations.

On receiving the verbal request over the telephone for material the shop delivery switchboard operator fills out the order or requisition which is taken together with the material to the shop by one of the material truckers who brings back the signed requisition on returning to the stores department. Power tractors with suitable trailers



Standard templets are used to save time in laying out boiler sheets

are used for handling material and besides saving manual labor, get the material to the shop with the least possible delay. Experience has shown that 15 min. is the average time required for the delivery of material orders with this system. A particular advantage of the telephones is that in case of emergency and where the material is in stock, immediate delivery can be obtained. Since installing this system and using power tractors and trailers, the force employed in trucking material at the Burnham shop has been reduced at least 50 per cent.

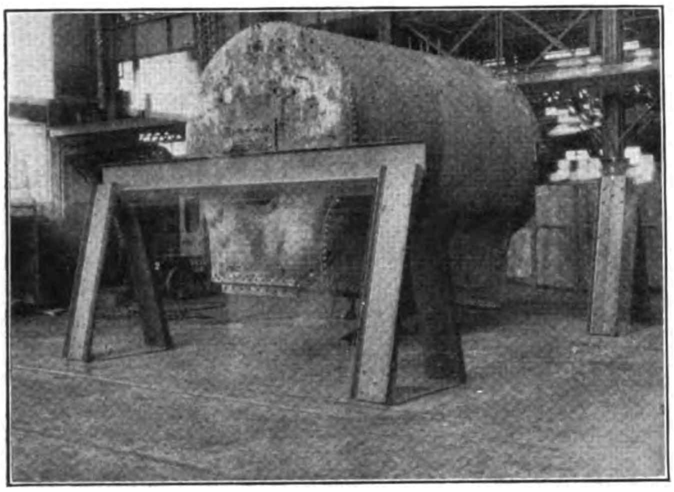
Labor saving shop devices

One of the illustrations shows a portable steam dome platform which has proved helpful in the handling of throttle work as well as in providing greater safety for the men who are doing this work. This platform consists of a built-up steel and wood platform 6 ft. square and having a hand or guard rail made of 2-in. pipe or flue material, 2 ft. 6 in. above the floor. A hole 3 ft. 9 in. in diameter is provided in the center of the platform, enabling it to slip down over the largest steam dome, most of the weight being supported by the platform floor resting on top of the boiler. Stability is secured by means of four V-shaped brackets, two of which bear on the barrel of the boiler on either side of the dome. The two brackets on the left are shown in one of the illustrations. These brackets are made of 5/8-in. by 4-in. bar stock, riveted to the platform floor. Two hooks are provided on opposite corners of the rail to which the crane chain hooks can be readily applied. They serve to lift the platform from the erecting shop floor onto the boiler or back to the floor again as may be required.

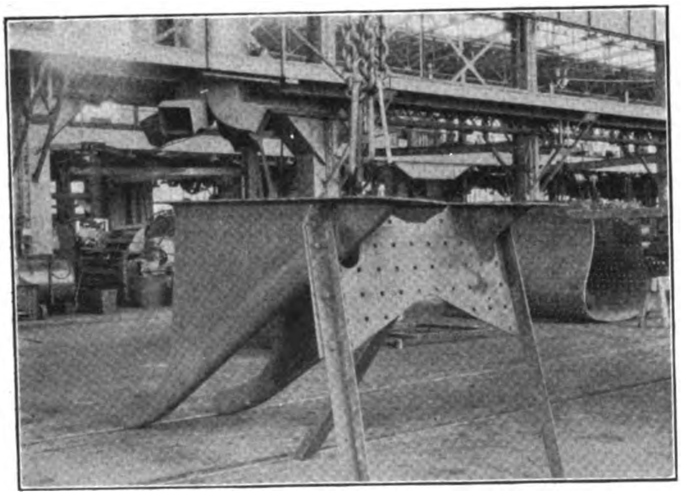
Solid and tubular bar stock of all kinds is kept outside of the locomotive shop in rugged racks built up of heavy timbers with horizontal rail sections and provided with umbrella type roofs as a protection against rain. When certain of this stock is required to be worked up in tur-

ret lathes in the shop it is passed directly to the machines through a hole in the shop wall as shown in one of the illustrations. This is merely a simple method of saving work in handling the heavy bars.

An effective method of handling shop blue prints is in vogue at Burnham. It consists of mounting commonly used blue prints on scrap sheet iron of standard sizes and hanging them on suitable racks. Shellac is used both to make the blue prints adhere to the sheet iron and as a surface protection against oil and dirt rendering the prints unreadable. A hook riveted to each sheet, as shown in one of the illustrations, enables the sheet and blue print to be suspended in its proper place in a compact rack in the toolroom or, when out on the job, from some part of a machine or bench where it can be readily seen. As a result of this method of handling blue prints they take up minimum space when not in use; any particular print may be readily found when required; durability is secured and blue prints when at the machines or work benches can be used with maximum convenience. The main filing rack in the toolroom consists of a substantial angle or T-iron supported on 2-in. by 4-in. diagonal wooden legs at a distance of 4 ft. 9 in. above the floor. Beneath the angle iron, and supported at about 12-in. intervals from it, is a ½-in. rod from which the blue prints are suspended by means of the hooks. When a considerable number of blue prints are used constantly on a particular job, as in the brass or air brake room, they are kept at that point on a small rack which may be placed in some corner where it will be convenient but out of the way.

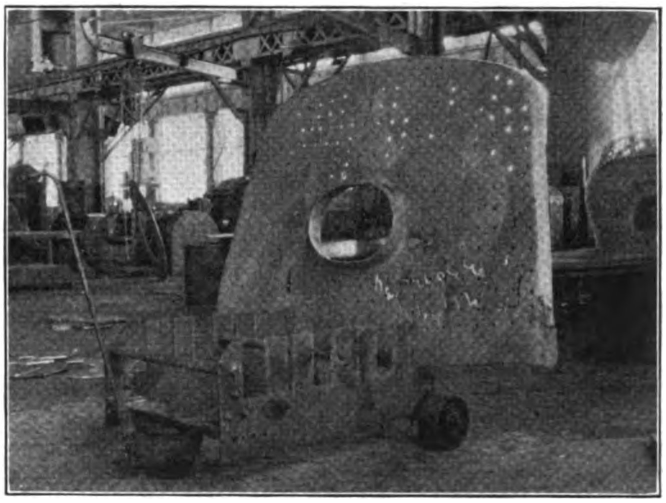


By means of this pair of horses, boilers can be rotated and blocked in position for boilermakers to work to the best advantage



A convenient stand for use in applying Nicholson thermic syphons

The problem of storing smoke box fronts is often difficult, particularly in a congested shop, and one of the illustrations shows how simply this is handled at Burnham. A rack built up of ½-in. or ⅝-in. scrap boiler plate, and having slots of suitable size and properly spaced cut with the oxy-acetylene torch in the upper edges of the rack, is located outside the shop building. After a smoke box front is removed from an engine in the shop for general repairs or other work involving the renewal of front end netting and parts, a storage battery truck with jib crane attachment picks up the smoke box front and carries it out of the shop, setting it down in a vertical position in one of the slots in the rack. By this means it is taken completely out of the shop which may be otherwise congested, occupies a minimum space while being stored, and moreover is set in such a position that there is no danger of workmen falling or tripping over it. It will be observed from the illustration that the two sides of the rack are held together by suitable tie rods, the proper spacing being secured by scrap tube sections of the proper length.



Completed or partially completed flue sheets are placed in this truck on which they take up minimum floor space and are readily moved about the shop

Templets are used in laying out standard boiler sheets saving an immense amount of time and assuring accuracy. Each templet when in use is clamped to the boiler sheet during the laying-out process to obviate any possibility of slipping while the center punch marks are being transferred through the templet to the boiler sheet. A complete set of templets is kept under the horses shown in the illustration.

The method of renewing fireboxes at Burnham is to strip and cut off the entire back end of the boiler, using an oxy-acetylene cutting torch. The back end is then taken to the boiler shop and supported at approximately its center of gravity on two horses as shown in one of the illustrations. The horses are built up of channel and I-beam sections riveted together and of sufficient strength to support the heaviest back end. The weight of the back end is transmitted through two trunnion plates to bearings on the horses and, by means of suitable blocks and a clamping arrangement, the back end can be held in whatever position may be most convenient for the boilermakers who are renewing staybolts, mud ring rivets, or other work. In other words, this arrangement makes it un-

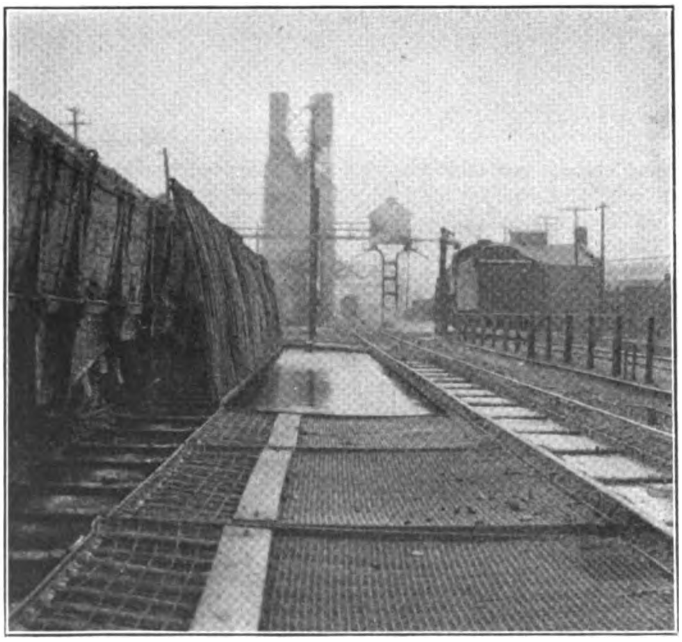
necessary for boilermakers to apply staybolts and rivets upward or at an angle which may make the work difficult. Any necessity of working in a cramped position or limited space is avoided.

The operation of applying Nicholson thermic syphons to boilers is somewhat awkward owing to the shape of the syphons and the rather limited room in which the boilermakers must work. The three-legged, built-up sheet metal stand illustrated has proved especially convenient for this purpose, there being slots in the upper part of the stand to hold the pair of syphons at the correct distance apart and approximately in the position they will assume when in the firebox. The boiler back end is then lowered down over the syphons, the upper edges fitted into the openings in the crown sheet and welded and the entire operation performed with much less difficulty than if the syphons had to be held in position entirely by hand.

A three-wheel truck, designed for holding and transporting various flue sheets and other boiler sheets about the shop is also illustrated. This truck consists of a substantial boiler sheet framework supported on three truck wheels and provided with slots of different widths cut with the oxy-acetylene torch in such a way that boiler sheets in various states of completion as regards forming the flanges, can be held upright in the truck. The sheets will in this way take up comparatively little floor space and may be readily moved about the shop.

Safety covers for water type ash pits

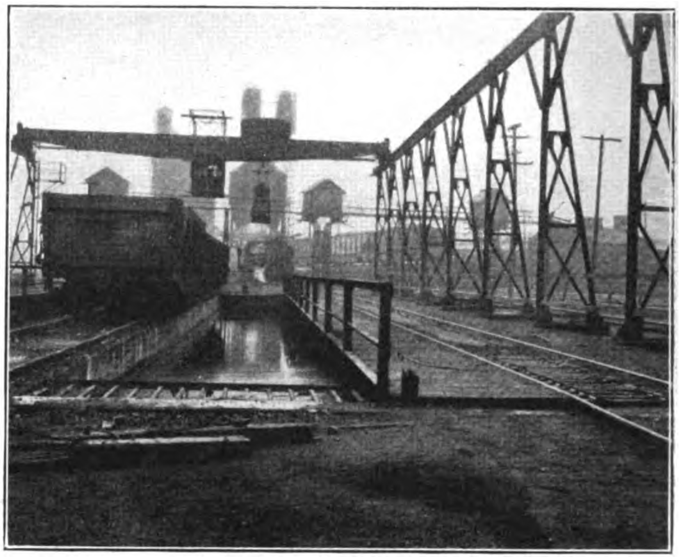
THE water type of ash pit which is quite commonly used at the majority of modern engine terminals offers many advantages over the older types of pits, but at the same time, presents an element of danger



The covers are supported against the cars and must be lowered before the cars are moved

which has proved to be quite difficult to eliminate—the possibility of ash pit men either falling in the pits or unconsciously stepping off the wrong side of a locomotive and into the pit. The two illustrations which accompany this article show two different arrangements installed at the Joliet, Illinois, engine terminal of the Elgin, Joliet and Eastern, that have successfully eliminated the dangers in connection with the instillation of an uncovered, open water type of ash pit.

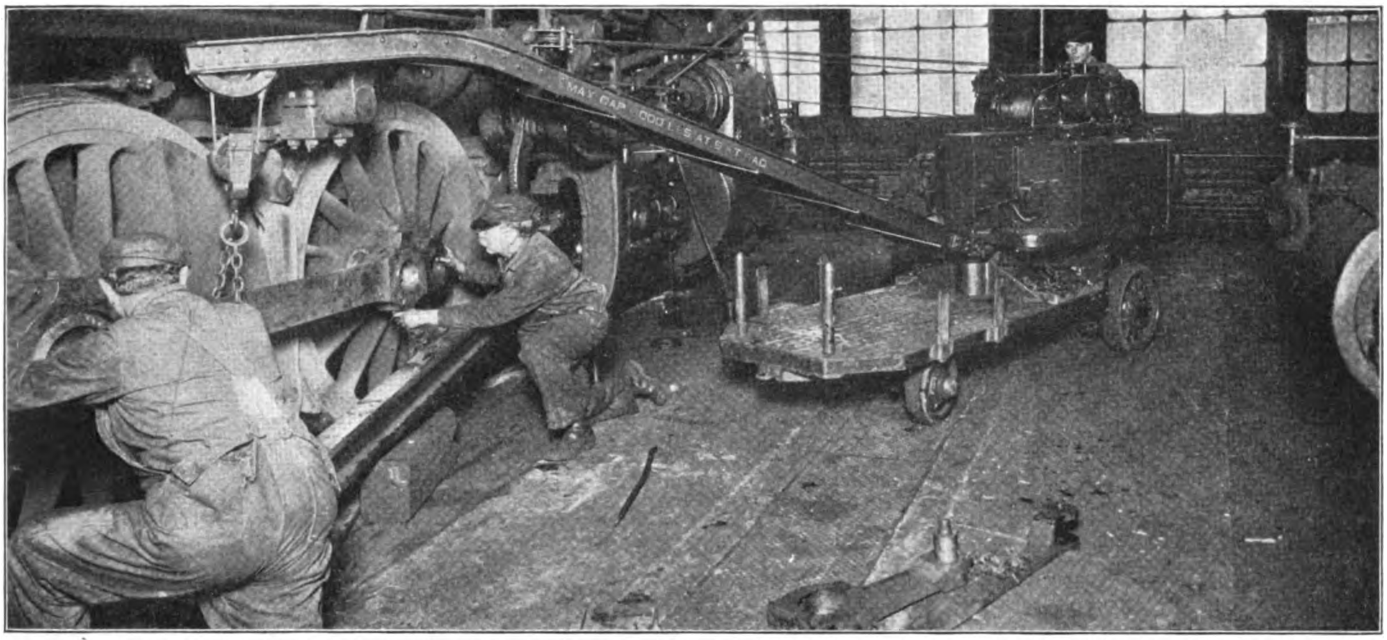
There are two ash pits at this engine terminal, one illustrated in each of the pictures. It will be noticed that on one of the pits a grating constructed of boiler tubes has been laid between the rails over the pit, and on the inside of the pit track towards the center or service track has been placed a runway with a railing, so that no matter from which side of the locomotive a man should



The runway on the pit side eliminates the danger of a man alighting from the wrong side of a locomotive

happen to alight, there is no danger of his falling into the pit.

The arrangement of the grating over the other pit seems to be still better. Many railroads throughout the country have devised gratings to be placed over ash pits of this type and it may be safely said that in the majority of instances, these gratings may be placed over the pits in such a manner that the operator on the ash pit crane may pick up the gratings and lay them on the ground while cleaning out the pit with the clam shell bucket. Gratings arranged in such a manner have one disadvantage in that it is very easy to neglect to replace them when through cleaning out the pit and, as a consequence, they fail to serve their purpose. The arrangement shown in the second illustration differs from the ordinary type in that the gratings are hinged to an I-beam support which runs along the pit adjacent to the center or service track so that when it is desired to remove the ashes from the pit with a clam shell bucket, these gratings are raised and must be supported against the cars on the service track. It can readily be been that it is almost impossible to move the cars from the service track after the pit has been cleaned without lowering the grating into place and in this way, the fact that they are hinged and rest against the cars serves as an automatic safety feature. The gratings themselves are constructed of light weight material principally a light angle iron outer frame and cross bars of 2-in. boiler tubes flattened at the ends and riveted to this frame. Over these cross bars is laid a close mesh netting and a plank runway. It will also be noticed that there are cross bars between the rails of the ash pit track which support a grating that is just beneath the surface of the water in the ashpit.



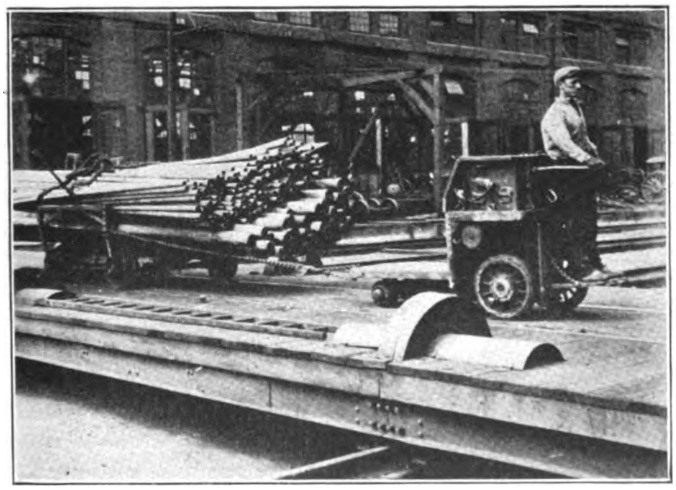
The crane type truck as it is used for applying side rods.

Electric trucks in the locomotive repair shop

The practice of one railroad indicates that this equipment fills a definite need

By Harold J. Payne
The Society for Electrical Development, Inc.

THE size of modern steam locomotives is so great and construction is so complex, that the problem of stripping and rebuilding requires special facilities. The overhead traveling crane is indispensable in this connection and given sufficient time, can handle all of the work to be done. In the particular shop in question, however, 40 locomotives are placed at a time in each of two buildings and although each building is equipped with two cranes, it is still found that this apparatus is not equal to the number of tasks imposed upon it. Since in addition to the boiler tubes, 125 or more parts have to be taken off and replaced on each engine that is completely overhauled, this can be readily understood.



An elevating platform truck used as a tractor

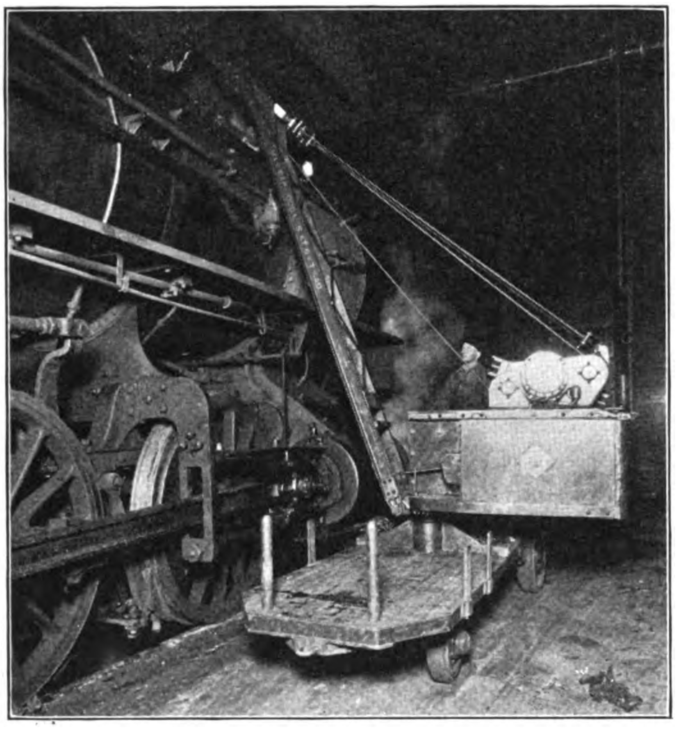
Another class of work for which it has very commonly been found difficult to find adequate equipment in such shops is the handling of parts from the locomotive to the various sections of the repair shop where cleaning machining, forging, annealing, etc., are done. Distances are frequently long, parts are heavy and are moving between points that vary considerably in location from hour to hour—especially as in this case where 80 locomotives are being repaired simultaneously. Quite evidently any carrier that is to work out in such service must be at the same time sturdy in construction and flexible in operation.

Storage battery trucks adopted

With these two problems in hand the shop under discussion decided about four years ago to experiment with storage battery trucks as a possible solution of these difficulties. The original idea was to provide auxiliaries for the heavy cranes and for hand trucks. That being the case two types of truck were put into the service, the load carrying crane and the elevating platform. At present the management finds itself convinced not necessarily of the particular make of equipment nor the particular modifica-

tion in use, but of the suitability of trucks for this kind of service. It can be said that each of the eight machines in service does more work than five hand truckers. The more or less intangible results that have been achieved, however are of still greater importance.

The most important of these is the supplementary service rendered the overhead cranes. Formerly when a part was ready to be raised or lowered, it was necessary for the crew to wait for the overhead crane; time was unavoidably lost since it was a physical impossibility for two such machines to be in a half dozen places at a time. With the crane trucks now performing all of the lighter jobs the traveling cranes are always available for the work for which they alone are fitted such as lifting a rear end or front end or perhaps moving a boiler. By far the larger number of parts stripped weigh under three tons and are located within easy reach of the boom of the crane truck. Consequently, this work has been largely assigned

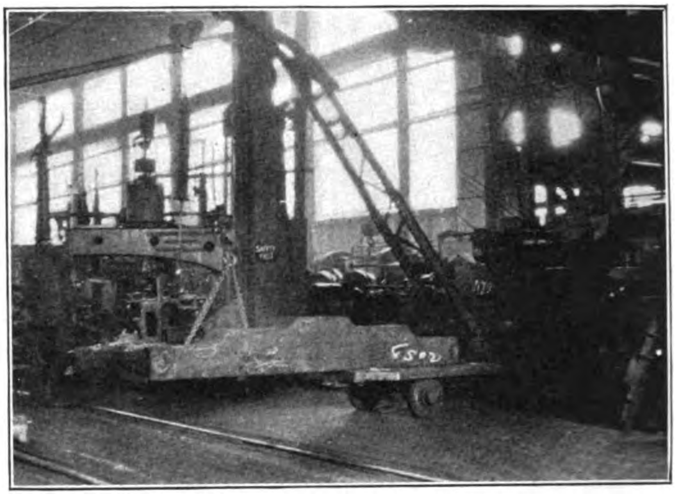


The boom is long enough to remove parts from the top of the locomotive

to these auxiliaries, with the result that taking down and building have been generally accelerated. Furthermore, idle time on the part of repairmen has been cut down and in some cases the number of moves necessary to perform a given job has been decreased. For instance, when a couple of driving rods are taken off that are needed immediately in the machine shop, the crane truck drops them onto the platform of its own chassis and delivers them to the machine that is to do the work, traveling a thousand feet and back again, probably dropping a load of finished parts by a nearby job on its return. By the time it is needed again for another job, on the locomotive being stripped, it is ready.

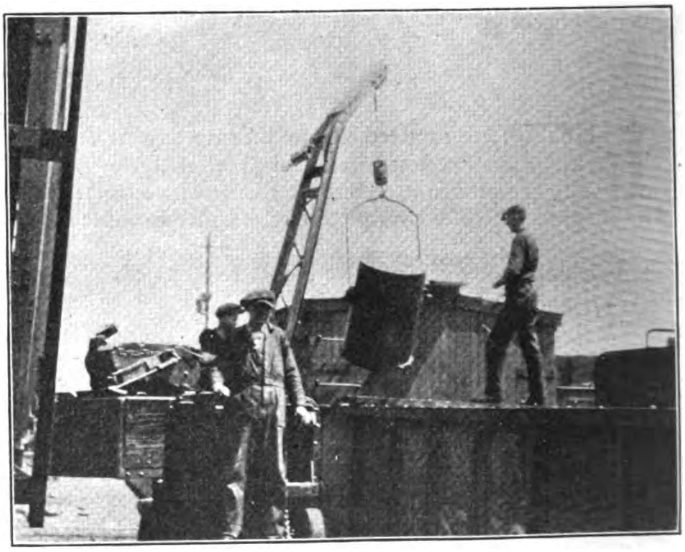
Work done by elevating platform trucks

The elevating platform type of truck with skids supplements the crane type in the work of moving the parts through process. Wooden platforms and metal box skids are used in connection with these trucks which are constantly on the move between the locomotive shops and the other departments. In general the metal boxes are used in the blacksmith shop for taking parts that are still hot directly from the workman or the machine, as the case may be, so that rehandling may be altogether avoided. The wooden platforms are used for all parts up to three tons, a typical load consisting of six or eight locomotive truck springs. It is impossible to detail the jobs done by the storage battery equipment because of the fact that it is used very much as are machine tools. In other words, the



Large castings are carried on the chassis with the aid of the crane

truck is a tool called upon to lift, carry or pull, irrespective of the nature of the job, so long as the total load does not greatly exceed the known capacity of the trucks, a capacity somewhat greater than the two tons in this particular case, which is guaranteed by the maker. Perhaps by citing a few "odd jobs" for which the trucks have indicated fitness through their performance, a somewhat



Chips are carried out and dumped into scrap cars with the crane type trucks

clearer picture of what they are accomplishing may be gained.

Saving on chip removal

Formerly nine wheelers were busy all day long keeping the machine shop clear of chips. The distance that had to be traveled to the siding on which the car was placed that carried away these chips frequently exceeded 1,000 feet and always included a curving up grade of about 6 per cent, 40 feet long. When the crane trucks came into

use the experiment was tried of carrying out the chips in cans, each holding the equivalent of six wheelbarrow loads. On every trip the truck carried four to six of these containers. The net result of this innovation has been a reduction of the labor involved to that of two truckers, each with one helper, working only one hour and 20 minutes a day. The congestion caused by nine wheel barrows constantly moving through the shop has been eliminated. This was particularly gratifying as the aisleways are exceedingly narrow considering the volume of material necessarily constantly on the move. Actually the main runway through the machine shops that are placed at right angles to the locomotive shops, is not over seven feet wide.

Boiler tubes when removed for cleaning and safe ending are placed behind the locomotive on a special flue wagon that runs on standard gage track. When the load is ready, it is run out onto the transfer table and from the table to the flue shop. Formerly 10 men were required for placing the flue wagon on the table and later for pushing it into place in the shop. By the method at present in use, a truck of the elevating platform type

Elevating platform used for unloading wheels from a car

is used to haul the load of tubes. The truck is coupled to the flue wagon and the machine used as a tractor has no difficulty in moving the load. One man can do the job in a shorter time, and entirely without physical effort, that formerly demanded 10 men normally at work on other jobs.

Special spring bumpers have been attached to the front end of the platform trucks to fit them for shoving loads that may be placed from time to time on other wagons or push cars that run in the main aisleways on a standard gage track. Again the trucks are used in spotting cars when a switching engine is not immediately available. Regularly the platform trucks work between the stores department and the various sections of the plant delivering such supplies as may be needed. With equal regularity the crane trucks are used for loading outbound motor trucks carrying heavy stores for shipment to other plants or roundhouses. The complete flexibility of the crane truck is a great advantage in such loading where quarters are tight and overhead cranes are not available.

Building a transportation system

It is clear that in order to keep all of this fleet of 8 units operating efficiently at all times, a transportation organization is desirable. This has been recognized and one man has been given complete charge of the equipment and is entirely responsible for service rendered. The foremen in charge of various sections of the shop are expected to make known to him any special work that is to be done. To speed up movements and to reduce the number of empty runs, a system of flags has been adopted for placing on work waiting to be moved. These are small metal markers, painted yellow with a black letter designating point of destination. The first driver passing such a job without a load is expected to pick it up and move it. The transportation chief is constantly alert throughout the various shops making sure that no jobs are being neglected and dispatching the truck drivers for special work when need arises. Special effort has been made in assigning definite jobs to various truckers to reduce the time to a minimum that they must travel empty.

Another man is constantly at work keeping the trucks in good running condition and preventing truck failures. This man is able to inspect all of the trucks regularly and to make sure that they are properly lubricated.

Although costs of operation are not known definitely at this shop, other data reveals that a charge of $4 a day per truck covers the items of interest, depreciation, maintenance and power in similarly heavy service. Beside saving five times the wage of a hand trucker at a cost of about $4, many worthwhile changes are made possible in shop routine.

The electric industrial truck is seldom thought of as a machine tool, yet performance in this locomotive repair shop justifies the contention on the part of the management that it falls naturally into this class of equipment and that as such it has come to stay.

Cooling and drying compressed air

By J. B. Leonard
American Blower Company, Detroit, Mich.

The problem of eliminating moisture in compressed air is one which has proved a source of worry in many industries throughout the country. Varied have been the remedies which have been applied but in the opinion of the writer, an installation such as the one at the car shops of the Michigan Central, Detroit, Mich., has many distinct advantages, both from the standpoint of effectiveness as well as cost.

These shops were using compressed air in large quantities for operating pneumatic machine tools. This, of course, meant that the air had to be practically free of moisture. In order to solve this problem, it was finally decided to install a system for cooling and drying the compressed air, an elevation and floor plan of which is shown in the sketch. This system is comparatively simple and when once installed, requires little attention. The installation, as shown in the sketch, consists of four No. 40 American Blower pipe coils which are made of standard 1-in. pipe set in cast iron bases of 5 ft. 6 in. and 5 ft. 9 in. length, respectively. Each coil has 160 vertical pipes, arranged with 40 tubes in a row extending the length of the base and four rows wide. The bases are of special construction, having a vertical web along the entire length, dividing the base into two distinct chambers, so that the compressed air will follow different routes and eliminate any possibility of short circuiting.

Referring to the floor plan of the sketch, it will be noted that these coils are used as aftercoolers, designed

to reduce the temperature following the final compression, thus removing a large portion of the moisture content. It was found advisable when operating during the winter months to eliminate all of the moisture possible from the compressed air before it entered the pipe lines, as frost accumulated on the inner surface of these pipes, increasing the pressure drop at the end of the line. In the accumulation of this frost, the walls of the pipe tended to serve as a surface condenser which caused moisture to form on the inside.

A two-stage air compressor, having an intercooler between stages, is used to compress the air to 100 lb. gage pressure. The amount of heat to be removed per hour with a capacity of 1,000 cu. ft. per min. at 100 lb. gage is approximately 600,000 B.t.u. The temperature of the air after leaving the compressor is 225 deg. F., which is reduced to approximately 90 deg. F. after passing the cooling system to the storage tanks.

No use is made of the heat extracted from the compressed air and no provision was made for the mechanical circulation of cooling air around the coils to increase the radiating capacity. One-fourth of the total volume of the compressed air passes through each coil, thus maintaining the velocity within a practical figure. The radiation factor found to exist with this installation was considerably higher than expected, due perhaps to the coils being located outside the building and a comparatively high velocity of air over the coils.

The recommended radiation factor, loss in B.t.u. per sq. ft. per degree drop in temperature per hour, should not exceed three, under the conditions occurring in this installation. In the analysis of a problem such as this, it is advisable to prepare a heat balance between the heat in the compressed air which must be removed and the radiating capacity of the pipe coils sufficient to handle the job. The following formula is used for determining the amount of heat that must be removed from the compressed air per hour:

$$\text{B.t.u.} = \frac{60\, C_1 T}{55}$$

in which
C_1 = the cubic feet of free air entering the compressor per minute.
T = the temperature of the air leaving the last stage, minus the temperature desired at the coils.

The volume of free air entering the compressor may be found by the use of the following adiabatic formula;

$$C_1^{1.41} = \frac{P_2\, C_2^{1.41}}{P_1}$$

in which
C_1 = the number of cu. ft. per min. of free air entering the cylinders.
P_1 = absolute atmospheric pressure.
P_2 = absolute pressure at the last stage.
C_2 = the number of cu. ft. per min. leaving the last stage.

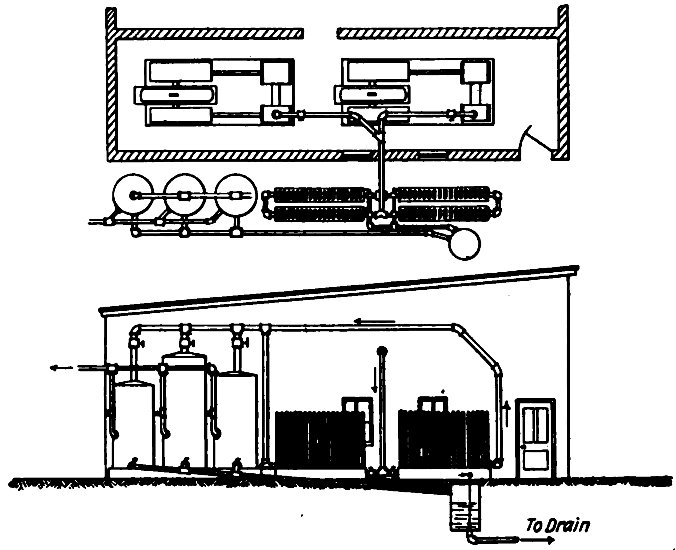
The moisture contained in the compressed air at any point of the system may be found by simply applying the conditions of temperature and pressure existing at that point to the following formula taken from Kent's Mechanical Engineer's Handbook:

$$W = \frac{KH}{2.036\, P - H}$$

W = the weight of water in pounds.
K = the ratio of the weight of 1 cu. ft. of saturated air to 1 cu. ft. of dry air.
H = the elastic tension of water vapor.
P = the absolute pressure in pounds per square inch.

Each of the coils must have two drain pipes to the condensation tank on account of the center web, the valves being left open continuously. The condensation tank is emptied periodically by turning a lever which is located on the floor directly above the drain tank, buried in the ground in front of the right hand coils, as shown in the sketch. The opening of this valve permits the pressure of the air above to force the water out at the drain pipe.

Calculations show that the moisture content of the air, with 100 lb. gage and 90 deg. F., to be approximately 25 grains per pound of air. The success of this installation is apparent when one realizes that the moisture entering the system was approximately 100 grains per pound of air. In a plant of this capacity, about five pounds of water enters the first stage of the compressor per minute. Half of this is eliminated at the intercooler, where the pressure from the first stage is about 30 lb. gage and the temperature is reduced by the cooling water to about 85 deg. F. It is possible with the cooling capacity of this installation to extract an additional 1¼ lb. of water per minute, which necessitates a condensation tank having



Sketch showing the compressed air cooling and drying system in the car shops of the Michigan Central, Detroit, Mich.

a capacity sufficient to contain the moisture drained from the coils for a period of from eight to ten hours.

There are undoubtedly other arrangements which could have been used to as good advantage. However, the choice of any arrangement depends upon the conditions present. The question of utilizing the available heat from the compressed air is a matter dependent upon the continuity of operation, but as the demand for compressed air is somewhat variable, and the compressor is generally controlled automatically, it would appear that to depend upon a continuous source of heat would be taking unwarranted chances.

Should the limitations of space prohibit such an installation as this, it might be advantageous to use smaller coils and provide a fan for the circulation of cooling air, thus obtaining better and more positive results. With a positive circulation, it would also be somewhat easier to predict the results that could be obtained.

THE AVERAGE COST per ton of coal used as fuel for road locomotives in freight and passenger train service for Class I roads in July was $2.68, as compared with $2.98 in July last year, and for the seven months of 1925, including July, the average was $2.77 as compared with $3.15 last year, according to the monthly bulletin of fuel costs compiled by the Interstate Commerce Commission. This covers only fuel charged to operating expenses and does not include switching and terminal companies or fuel for switching locomotives. While the cost of coal shows a reduction the average cost of fuel oil per gallon increased, from 2.89 to 3.33 cents for July and from 2.75 to 3.18 cents for the seven months period. The total cost of coal and fuel oil for July was $25,285,608, as compared with $25,785,903 for July, 1924, and the total for seven months was $188,403,445, as compared with $211,374,783 last year.

Needle valve reseating tool

By Glenn L. Davis

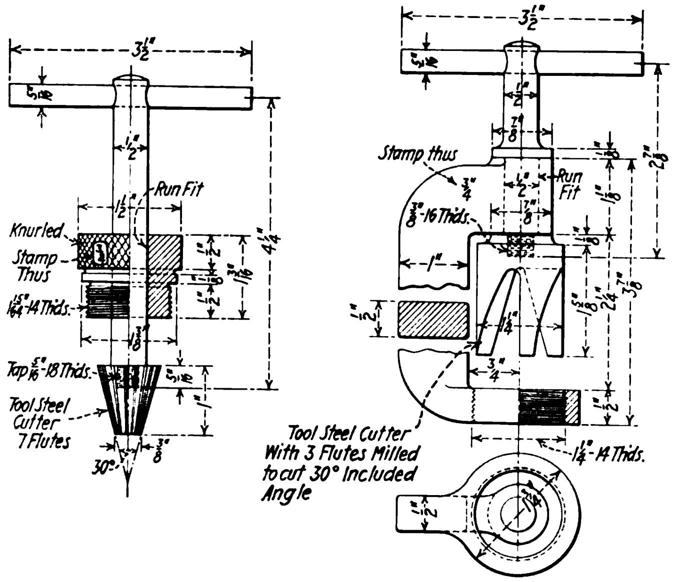
WHERE the locomotive shop toolroom was formerly considered as merely an added overhead burden—a necessary evil—it is now looked to as the originator of time-saving devices and methods and it is worthy of note that, in general, toolroom foremen are measuring up to their new responsibilities and heartily co-operating with tool designers in producing jigs, fixtures and small tools of greater perfection. An example of improvement in railway tool design is shown in the accompanying illustrations.

Needle valves controlling the flow of oil to oil burners of various types, require maintenance of the highest quality to prevent serious leakage losses and leakage dangers. The tool shown in Fig. 1, reseats the valve seat and mills the end of the needle stem to produce an oil-tight joint.

The tool is made in two sizes for ½-in. and ¾-in. needle valves and it is believed, represents a distinct advance over the older method of using a reseating reamer similar to the one shown and, refinishing the needle stem in an engine lathe, or by means of a hollow mill driven in various machine tools. The primary consideration in designing tools of this class is to produce a compact, light, pocket tool so adaptable that it will do away with costly "stripping" to get at the repair job and the more costly replacing of the dismantled piping after the valves are repaired.

Fig. 2 shows the seat reamer removed from the frame. The knurled and threaded nut on the stem of the reamer fits into the threaded bonnet cavity of the valve body when the bonnet is removed and hand pressure on the reamer handle is sufficient for the slight feeding necessary in reaming the average seat. Since the thread on the bonnet of the valve matches the thread on the centering nut of the reamer it is obvious that, with the reamer removed from the tool frame, the valve bonnet, with the valve stem in place in the bonnet, can be screwed into the tool frame in place of the reamer and in this position the stem can be brought up against the hollow mill and refinished.

Fig. 3, which shows the tool completely disassembled, shows how the mill is held against end movement. Since



A tool which reseats the valve seat and mills the end of the needle stem to produce an oil-tight joint

no feeding movement of the milling cutter is possible with this arrangement, it is necessary to feed the valve stem to the work and this is accomplished by screwing the valve stem down through the internally threaded bonnet just as in closing a valve.

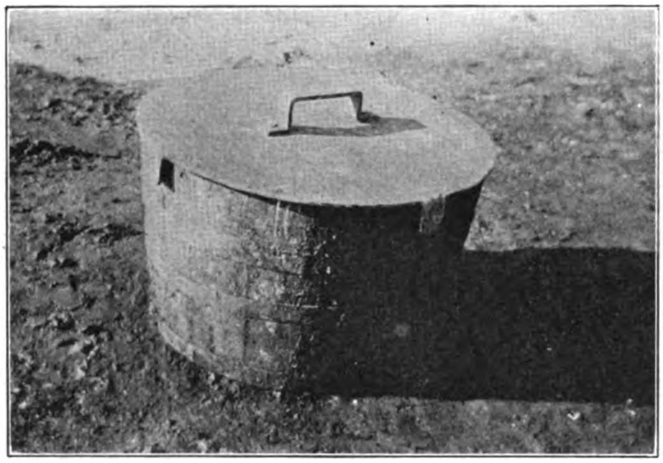
---

THE PENNSYLVANIA is equipping its dining cars with aluminum chairs, to be made by the Aluminum Company of America, Pittsburgh, Pa. The road aims to eliminate all fire hazards. The chairs will be so upholstered as to harmonize with the decorations. The Pennsylvania at the present time is operating 139 all-steel dining cars, and 10 new cars are under construction.

An inexpensive acid container

By Frank Bentley

A PRACTICAL container for the muriatic acid used to clean scale from injector and other small feed water parts is shown in the illustration. The receptacle is the lower half of a paint or oil barrel, the wood of which being thoroughly oil soaked resists the action of the acid for a long time. The cover of ¼-in. sheet iron is cut with four lugs to keep it securely in place over the top of the container. Together with its weight and ability to shed water, it is a safe and suitable covering. To a convenient depth, the half barrel holds the entire contents of one standard carboy of acid. When eaten out, the renewal of the barrel is a matter of but little time and expense.



Acid container used for cleaning the scale from injectors and other small feed water parts

Driving box calipers for use in limited spaces

By L. V. Mallory

Machine shop foreman, Missouri Pacific, Kansas City, Mo.

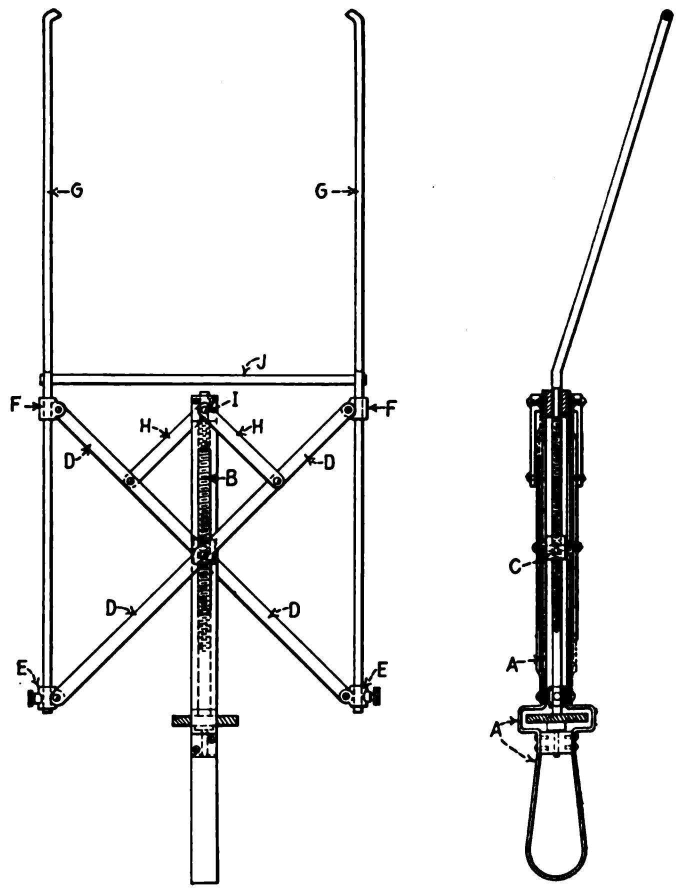
WHERE locomotives equipped with driving boxes of the removable brass type are used, it often becomes necessary to measure the journal diameter and the bore of the crown-brass seat in the box casting when fitting a new brass. This usually must be done without removing the box which leaves a limited space between the journal and the box casting that can not be measured accurately with ordinary calipers. A practical tool for making these measurements is shown in the illustration.

The frame *A*, made of ⅛ in. by ⅝ in. scrap steel, is braced by two small, brass, spacer blocks which also serve as the bearings for the adjusting screw spindles. The adjusting screw *B* is made of ¼ in. round steel which has cut on it standard threads, 20 to the inch. It has mounted on its lower end, a small knurled wheel which is housed in the handle in such a manner that it can be conveniently operated by the thumb. This screw engages the pivot block *C* which is threaded to receive it. The pivot block has a trunnion on each side that extends through slots cut in the frame *A*. Pivoted centrally to these trunnions are the cross-levers *D*, the lower ends of which are hinged to the stationary connecting knuckles *E*, while the upper ends are hinged to the sliding connecting knuckles *F*.

The caliper bars *G* slide through the knuckles *F* with the lower ends rigidly secured in the knuckles *E* by means of knurled, headed thumb screws. These bars are made from 5/16 in. drill rods with the upper ends bent at right angles to form the calipering points. The drawing shows the bars bent, also, just above the sliding knuckles which provides clearance between the axle and the handle and frame.

The upper ends of the two connecting toggle levers *H* are pivoted to the frame while the lower ends are pivoted to the cross-levers *D* at points midway between their upper ends and central pivots.

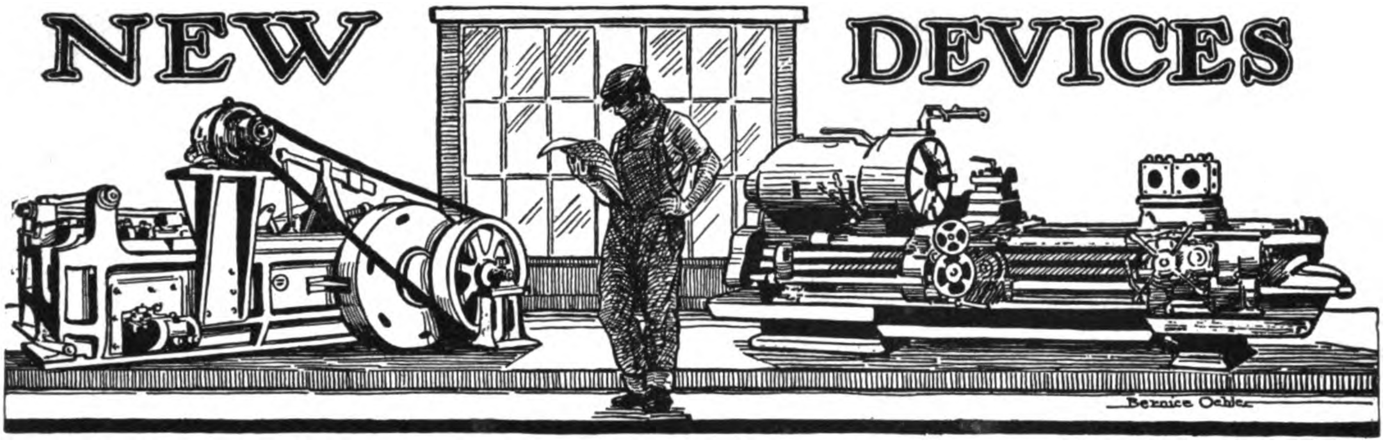
The principle on which the tool works is as follows: The adjusting screw *B* when turned, moves the pivot block *C* vertically between the frame and also moves the levers *D* because the pivot block forms the fulcrum of these levers. Since the connecting toggle levers *H* are hinged to the frame and the free ends connected to the cross-levers *D*, it is obvious that any change in the relative position of the pivot *C* and the fulcrum *I* of the toggle levers will cause them either to close or open the levers *D* according to the direction in which the screw *B* is turned. This action causes the knuckles *E* and *F* to act on the caliper bars G, thus opening or closing them in parallel lines.



Close quarter caliper for use in limited spaces

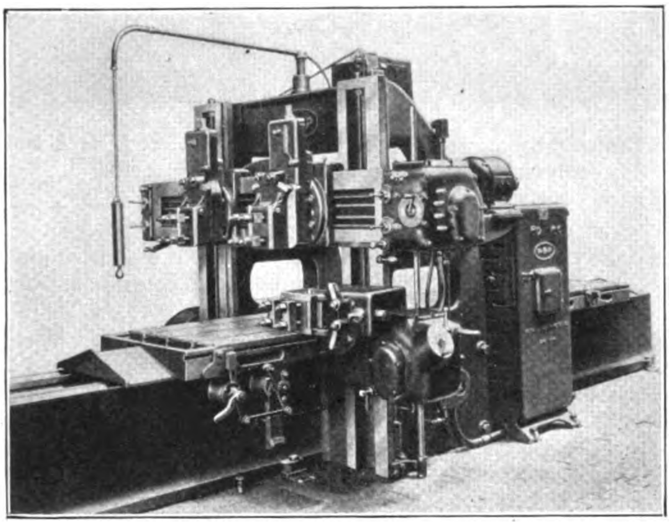
When used for calipering journals, the points face each other. When it is desired to use them as inside calipers for measuring the bore of the seat in the box-casting, the thumb screws attached to *E* are released and the bars *G* are turned half-way round so that the points face away from each other, after which they are firmly secured. A strong, rubber band *J* may be used to take up and lost motion which may occur in the joints.

This tool also can be used to advantage in calipering crank pins and rods when fitting floating bushings.



Planer with unique system of control

A NEW line of planers to be known as the Timesaver model has recently been placed on the market by the Niles-Bement-Pond Company, New York. This model is practically a new design throughout. In developing these machines every effort has been made to meet all modern requirements as to ease and convenience of operation, rapidity of control, safe operation and ample strength and power. An important point bearing on maintenance costs is the decided simplification of construction, many small parts formerly associated with planer design having been eliminated. This new model is furnished in 36-in., 42-in. and 48-in. sizes.



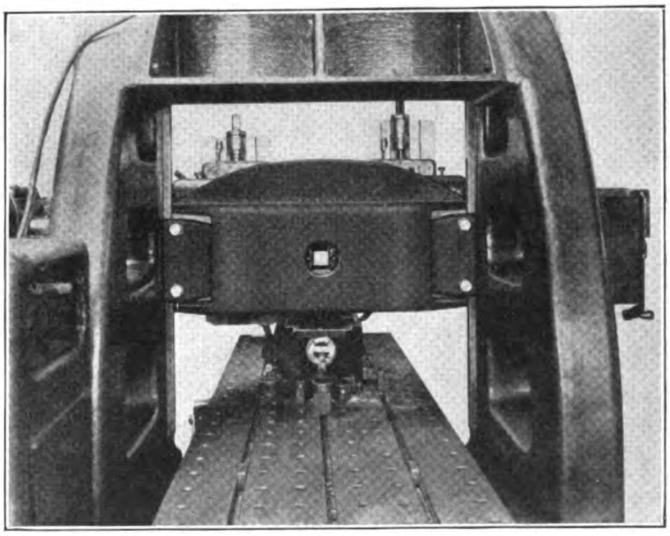
Niles-Bement-Pond Timesaver planer

Among the new and interesting features are electric feed and traverse for both crossrail and side heads; complete control from a pendant switch of all movements of the tool heads, crossrail and table. Another important feature in speeding up work is a duplication of control that gives the workman complete control of all important operations from either side of the machine.

In order to make the planer as easy and convenient as possible to operate and to greatly simplify construction, a motor is mounted at the end of the crossrail to feed the crossrail and side heads, to provide power traverse to all heads and to elevate and lower the crossrail. This motor is controlled by the pendant switch and the table dogs.

The direction of motion for either feed or traverse is determined by four-position levers at the end of the crossrail, one for each crossrail head. The levers are thrown in the direction in which the motion is desired. The feed and traverse motor is controlled by the pendant switch and the amount of traverse can be controlled either by the switch or by the levers. Another lever at the end of the crossrail engages the elevating and lowering of the crossrail.

As there are many times when it is a decided advantage to be able to control the machine from either side, an important feature is the duplication of all control levers. From whichever side of the machine is most convenient the operator has complete control of the traverse and automatic feed of the tool heads, the crossrail clamping and elevating and lowering as well as control of the table motion. The pendant switch can be pulled from one side of the machine to the other. The knob on the pendant switch has four positions, as is shown in one of the illustrations; in the upper or safety position all motion is stopped; in the second position down, the driving motor is controlled for setting the table with the work in the desired position relative to the tools; in the third position down by turning the knob back and forth the traverse of

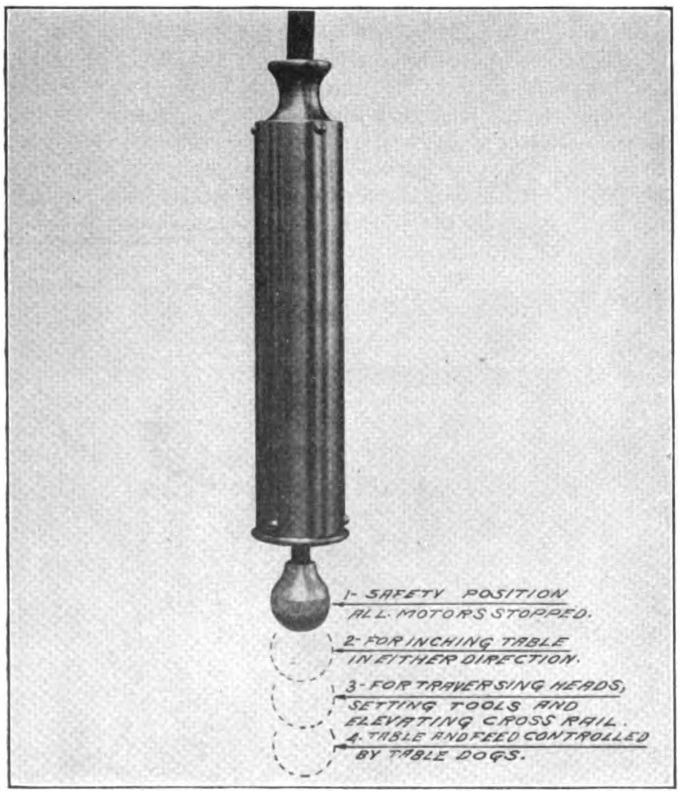


Rear view showing the cross-rail clamping mechanism—A stiffening web on the top of the rail is provided to resist the torsional strains

the heads and tool slides is controlled and tool can be set to the exact required position; in this position the elevating and lowering of the crossrail is also controlled. In the fourth position the table is started and the automatic feed engaged.

Perhaps the greatest step toward simplification on these planers is the electric feed. Ordinarily in the past, on planers of this size, the common practice has been to take the power for feeding the heads from the driving gears in the bed. This has, of course, made it necessary to connect the driving gears in the bed with the feed mechanism at the end of the rail and in the side heads through various gears, shafts and brackets. On the new planers, with electric feed through the motor on the end of the rail a great deal of mechanism has been eliminated. The usual "spring ratchet click boxes" with their troublesome springs and ratchets have been replaced by four-position levers.

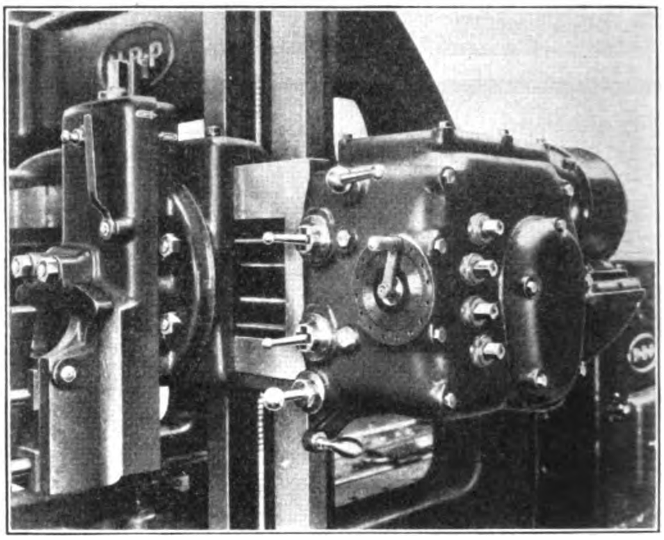
Another advantage of this electric feed is that the maximum feed can be obtained even on the shortest stroke. This results from the fact that with the electric feed the amount of feed possible is not in any way proportional to the length of stroke as is the case with the old type of feed box driven from the driving gears in the bed. By means of a switch the electric feed can be set to take place at either end of the table stroke. The feed is absolutely positive, there being no frictions or springs to get out of order. The selection of the amount of feed



Pendant switch showing the different control positions

is by direct reading dials conveniently located on the crossrail and side head; the side head feed is independent. The minimum feed is 1/16 in. and increases by sixty-fourths to 1 in.

Another time saving feature is the single lever crossrail clamp, so designed as to give an extremely powerful clamping action with an easy effort on the part of the operator. There is a lever at each end of the crossrail so that the crossrail can be clamped from either side of the machine. The operating levers are connected by a shaft running across the rail. A cam keyed to the middle of this shaft bears against a steel plate, as shown in the illustration, which is moved in and out as the operating lever is moved. The steel plate transfers the clamping force to the ends of the clamping levers which have fulcrums at the large bolts shown and bear against the housings thus rigidly clamping the crossrail. The difference between the clamp fit and the sliding fit between the crossrail and the housing is a matter of .0015 in. The clamping effort on the housings is therefore roughly in proportion to the ratio between .0015 in. and the distance



Micrometer collars, compact control levers, electric feed and traverse gear box and motor shown at the end of the cross rail

moved by the hand lever, a ratio which gives a tremendous leverage and therefore an extremely powerful clamping action.

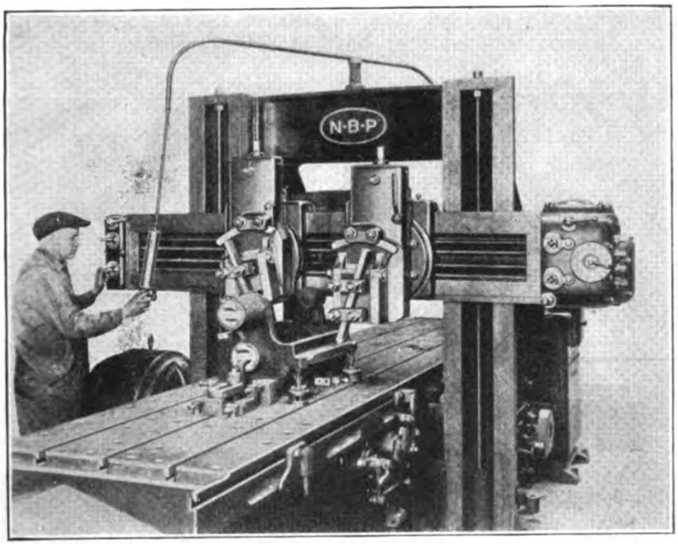
Every effort has been made to make the machine foolproof. The pendant switch is electrically interlocked with the rocker lever at the side of the bed so that when the pendant switch is pushed to the upper position to stop the table the rocker lever is made inoperative so that the table cannot be accidentally started by knocking against the rocker. An electrical interlock also makes it impossible to traverse the heads while the table is in motion and vice versa.

A safety coupling has been provided between the machine and the motor on the rail. This coupling is constructed so as to prevent damage to the machine if the operator traverses or feeds the crossrail heads together, if he traverses or feeds the side heads up against the crossrail, or if he lowers or elevates the crossrail against any obstruction. Again, the clamping levers for the crossrail are interlocked with the elevating levers so that it is impossible to throw in the elevating and lowering lever while the rail is clamped and vice versa.

The side head is designed so that the side head tool may be brought up close to the crossrail tool without any overhang on the crossrail tool slide. In order to do this, the side head is offset; that is, the feeding and traversing driving mechanism are kept below the head. The side head tool has also been brought up in line with the rail head tool. Where this is not done, the table stroke for any job requiring the side head will ordinarily have to be increased a distance equal to the horizontal distance between the tools.

The same gears are used for traversing and feeding the heads and elevating the crossrail and are all contained in

the gear box at the end of the crossrail which is filled with oil. Two large gears driving the small gears on each rod and screw are constructed so that they dip under the oil level and flood the entire box with oil. As an additional precaution, a single shot lubricator has been provided.



Here the operator is shown selecting the direction of motion of the back rail head with his left hand and controlling the amount of motion by turning the pendant switch knob with his right hand

The driving gears in the bed and the table rack are all made of steel and are of the Maag type. They run in oil and in addition, have oil pumped through directly to them. Holes have been drilled down the center of the driving gear shafts with connecting holes to the bronze bushings so that oil is pumped directly to the gear bearings. An oil pump is driven from the driving gears in the bed for furnishing forced lubrication to the table ways. Oil grooves have been planed in the table so that the oil is distributed evenly over the entire bearing surface. A single oil cup has been placed on each side of the heads for lubricating all of the various sliding members.

The gear box at the end of the rail is split so that by removing the bolts in the top cover, it may be removed and all the parts in the gear box are quickly opened for inspection.

The crossrail has been designed to resist the upward bending movement by providing a stiffening web on the top of the rail, and to resist the torsional strains and backward bending movement by making the crossrail deep. This, together with the crossrail gibs on the outside of the housings, and the clamping gibs on the inside, give the crossrail the necessary stiffness. The crossrail heads are offset so as to permit the tools in the heads to be brought as close together as possible.

The tool slides are wide and of full length so as to give the necessary stiffness even while the slide is extended down below the crossrail. The saddle is one solid piece extending around and bearing against the back of the crossrail so as to rigidly resist the cutting pressure at the bottom of the slide.

The bed is twice the length of the table so that the latter never overhangs the bed. Also, no part of the machine is below the floor line.

Boring mill designed for convenient operation

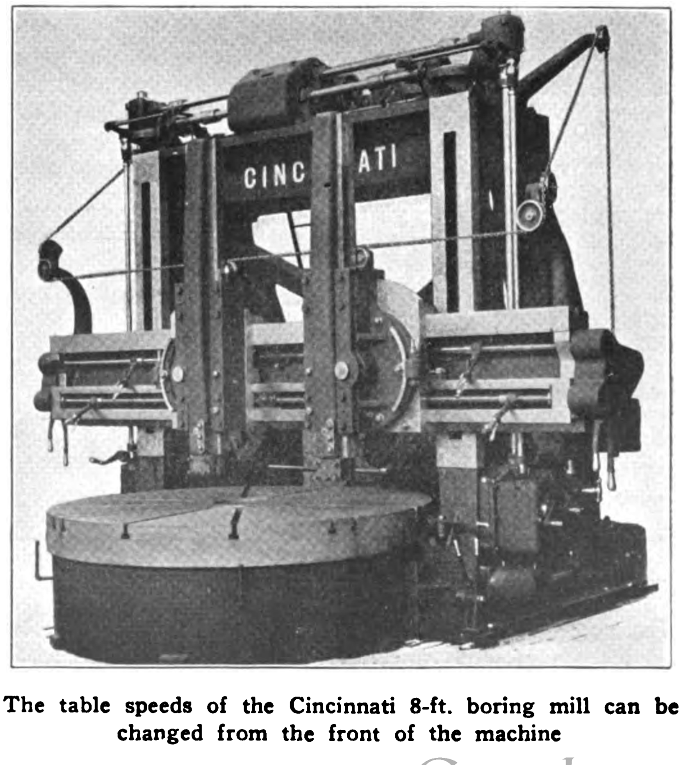
The Cincinnati Planer Company, Cincinnati, Ohio, has placed on the market an 8-ft. boring mill which it is said can be handled as easily and quickly as a mill of much smaller capacity without sacrificing rigidity in any part of the machine. Convenience for the operator, simplicity of design, elimination of wearing parts, and fool-proof arrangements to eliminate all liability of breakage, is shown in the centralized arrangements of all control levers and the operation of the rail lift, rapid power traverse to the heads, centralized oil distributors, etc.

Rapid power traverse to the heads vertically and horizontally is so arranged that by one movement of the operating lever the feeds are disengaged and rapid motion is imparted in the direction indicated by the movement of the lever. When this lever is brought back to a neutral position the rapid power traverse is disengaged and the feed engaged once more. The new design of this mechanism has eliminated all constantly revolving parts with the exception of the motor and one shaft on top of the machine. Safety features are incorporated throughout.

By rapid power traverse the heads are placed at approximately the position desired. Quick adjustment handles are provided for the final setting of the tool. With these the heads can be moved accurately any number of thousandths of an inch without the operator going to the end of the rail. Graduated collars are provided on both feeds for making these final adjustments. Feed changes to both heads are obtained on feed boxes located conveniently for the operator. They have direct reading feeds in inches per revolution of the table.

The rail is elevated and lowered through an instantaneous rail lift mechanism which is positively interlocked with the rapid power traverse and which has an automatic stop for the maximum height of the rail.

On boring mills of this size it has always been custom-



The table speeds of the Cincinnati 8-ft. boring mill can be changed from the front of the machine

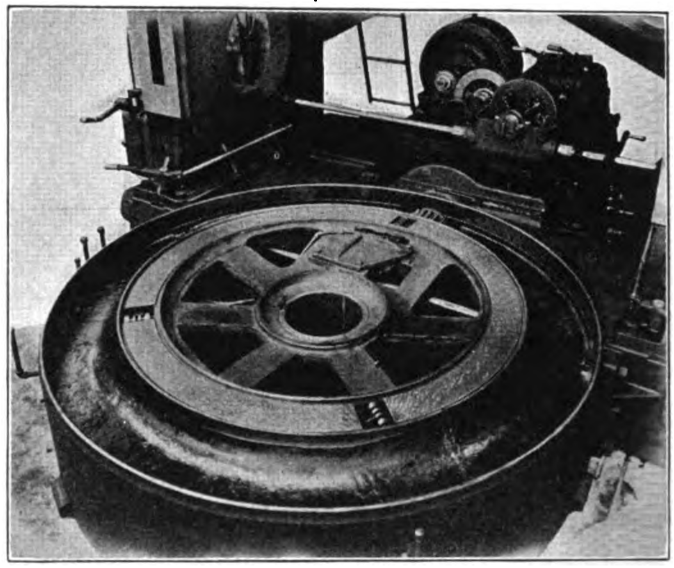
ary for the operator to go to the rear of the machine when changing table speeds through positive gears or clutches. This machine is arranged so that the positive changes in the main gear box are made from the operator's position in front of the machine. To further assist him in setting up work on the table a start and stop lever is used by means of which the table can be revolved any part of a revolution at the will of the operator. This lever operates through a clutch and brake on a high speed shaft in the driving mechanism. When a mill is driven by alternating current motor this feature is of great importance.

The speed gear box is so designed that it acts as a tie between the housing extensions giving additional rigidity to the base of the machine. All driving gears in this box are of steel and all speed changes are through positive clutches. The back gear shaft of this box extends through the front and receives a third bearing in the bed proper. The table pinion shaft also extends from the bed and receives a third bearing in the speed box. All bearings are of bronze and have ample facilities for oiling. All shafts not extending through the box are covered with oil and dirt tight caps.

The design of the bed is a decided departure from the accepted standard. The table bearing has been brought more nearly under the normal position of the load, thus lessening the tendency to spring the table. Heavy radial ribs are used and, as they are shorter are much more rigid. A ground spindle is pressed into the table, running in an adjustable bearing in the bed to compensate for wear.

Heavy housings with wide faces are used, these being mounted securely on large box extensions bolted to the bed and tied together at the back by the speed box. A box type arch ties the housings together at the top. This construction increases the rigidity of the machine when working at any height from the table as it gives sufficient depth to the housings to resist the pressure and bending movement from the tools. The rigidity is also increased by the use of diagonal braces which tie the housings together at the back.

All gears, including those operating the table drive, rapid power traverse and feed, are of steel, the table pinion being of heat treated chrome nickel. All bearings are bronze bushed and have ample facilities for oiling.



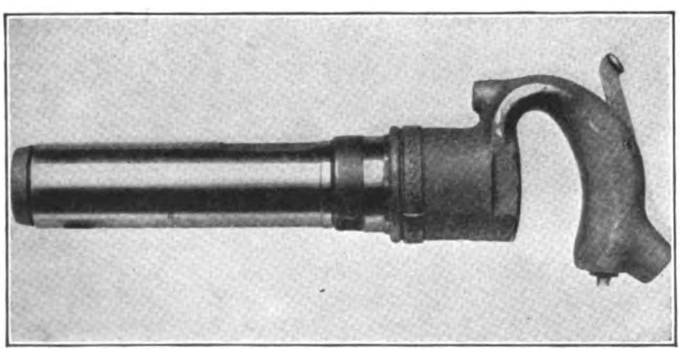
Cincinnati boring mill with the table removed showing the rigid construction of the bed—Note the construction of the gear box at the rear of the table

Oil cups and oilers have been displaced wherever possible by the use of centralized oil distributors which require filling only once in ten days. These distributors are used for all revolving bearings in both feed boxes and all mechanism on top of the rail.

Thor pneumatic riveting hammer

A PNEUMATIC hammer, known as the Thor riveting hammer, and embodying several important improvements, has been developed and placed on the market recently by the Independent Pneumatic Tool Company, Chicago.

The handle of this hammer is drop forged to shape from special alloy steel, particular care having been taken to leave plenty of stock at the bend and at the nipple lug. The handle opening has sufficient room for a large gloved hand and is shaped for a natural grip. The trigger is designed to have correct tension and is located to fit the hand grip. The throttle valve of this hammer is self-feeding, of the balanced type with spiral openings insuring accurate graduation for starting and control. The throttle valve stem, of hardened steel, operates in a bronze bushing. The handle is screwed on the barrel, large V-threads being used and the thread connection is exceptionally long. The handle lock is of the positive ratchet type held by an octagon milled on the barrel. The octagon gives eight positions for each tooth so the teeth always mesh tightly.



New Thor riveting hammer of improved design

The main valve is a hollow substantial sleeve without any portholes. The walls are of even thickness. The inside of the lower end of the valve is ground with a slight taper, eliminating danger of the piston striking the valve squarely. The valve has large and long surfaces, insuring long life, precision of timing and high speed. The exhaust and inlet are widely separated, thus tending to prevent leakage and loss of power. The valve is hardened and ground all over.

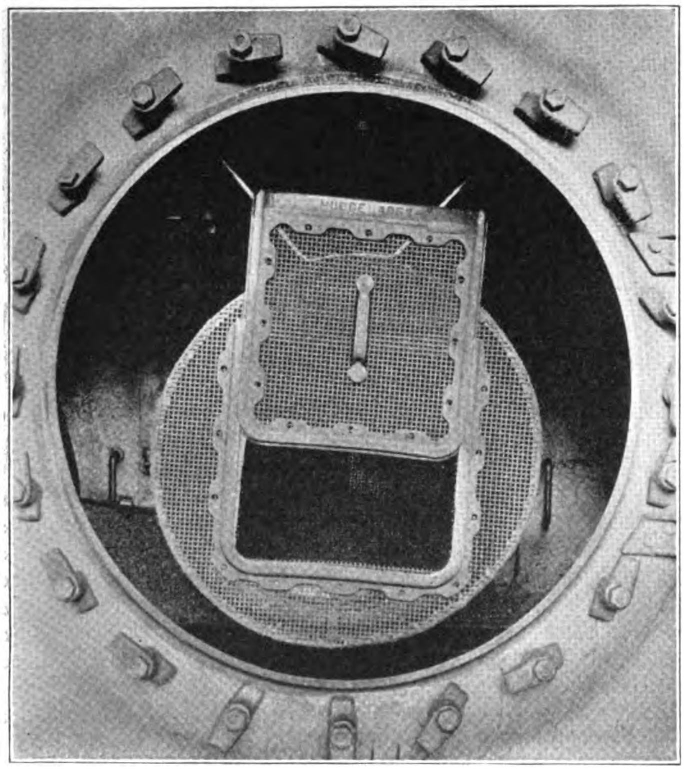
The valve block also is hardened and ground all over, portholes being laid out in straight lines, assuring direct passage of the air in its natural flow and eliminating any effect of wire drawing. The barrel is of alloy steel, heat treated, with the piston bore hardened, ground and lapped. The nozzle bore is hardened and ground. The exhaust at the upper end of the barrel is diverted at any angle which may be desired by the operator by turning a de-

flector. The throttle is designed with a special view to secure it in a certain position so that it will always stay tight while in service.

The hammer is symmetrical in shape, devoid of any projections or irregularities, and carefully balanced like the Thor chipping hammer. It is designed to have accurate regulation, delivering exceptionally rapid and powerful blows with no back kick.

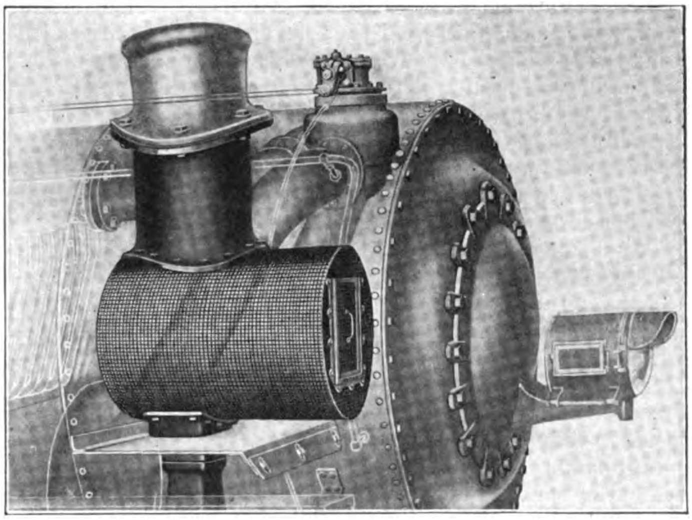
Security unit locomotive spark arrester

A DEVICE designed to prevent the emission of sparks from locomotives and reduce the cost of front-end inspection and maintenance work has been placed on the market recently by Mudge & Company, Chicago. It is called the Mudge security unit locomotive spark arrester. Special features of the design are the increased netting area which permits a larger exhaust nozzle, thereby reducing back pressure, possibility of complete inspection without removal, easy removal and reapplication when necessary, and the elimination of patching joints, always a potential source of trouble in a locomotive front end.



Front view showing spark arrester as applied to one of the three-cylinder locomotives built within recent months

The new spark arrester, shown in the illustration, is built as a unit, welded together and bolted to an angle iron frame apart from the front-end. It is installed through the smokebox front door as a unit without difficulty. The general construction of the spark arrester is evident from the illustration. It is built in the shape of a cylinder small enough to pass through the front-end door. The front and rear ends and seam of the spark arrester are reinforced by suitable angles bolted to the netting. The bottom of the arrester is bolted through a liner to the saddle casting, the top being bolted with a liner to the stack extension.



Phantom view, showing construction and application of Mudge security unit spark arrester

All patching of joints is eliminated in the Mudge curity unit spark arrester as it is entirely independent of any other part of the front-end. There is no interference with superheater or front-end throttle and it permits of complete front-end inspection without removal.

Open-side planer with rigid cross rail

THERE are many classes of work for which the greater convenience of the open-side planer is conceded. But some users of planers have been reluctant to buy machines of this type, fearing that it is impossible to secure the necessary degree of rigidity with the cross rail supported only at one end. In the open-side planer, which the Liberty Machine Tool Company, Hamilton, Ohio, is now building, there are numerous features that commend it to favorable consideration. Among these the question of a high degree of rigidity for the cross rail support has received especial attention with a view to overcoming the possible prejudice of those who would like to use open-side machines for handling jobs that cannot conveniently be set up on a planer with two housings. That this effect has been successful is well attested by the fact that under test on cast iron, with a cut 1½-in. deep and a feed of ¼-in., the maximum deflection at the outer end of the rail was found to be only .0035 in.

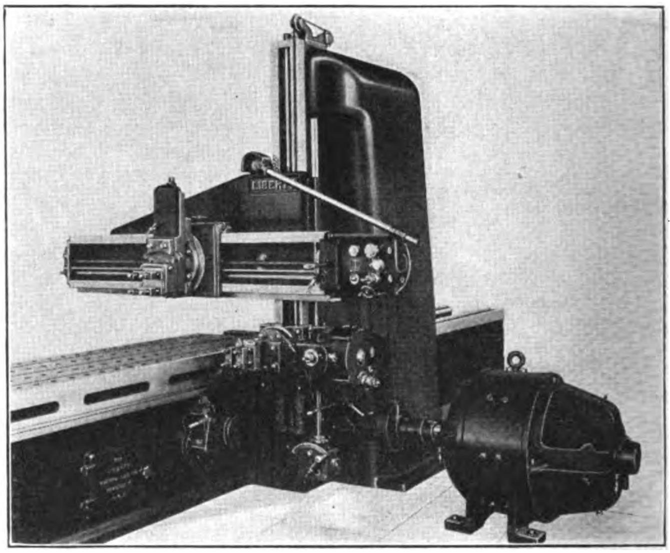
This degree of rigidity is attained through the provision of an unusually massive knee on which the cross rail is mounted. This knee hangs on liberally proportioned bearings on the column and is furnished with an arrangement of gibs for positively locking the knee in any desired position, which is accomplished by a hand crank on a shaft which transmits motion through two pairs of bevel gears

to a vertical screw connected with a taper gib. Turning of the hand wheel pulls this gib up and affords liberal locking power through the combined multiplying action of the screw and the wedge.

On page 122 in the February, 1925, issue of the *Railway Mechanical Engineer,* appears a description of a Liberty planer of the double-housing type. The present open-side planer includes all of the important features which have been incorporated in this machine. One motor is employed for driving the table while independent motors are furnished for the rail and the side head. This arrangement eliminates all overhead work and makes the cross rail and the side head fully independent units, capable of employing any feed or rapid traverse movement.

Elevating or lowering the cross rail and also the power rapid traverse of the rail head vertically and horizontally, are accomplished by manipulating a single lever. With this arrangement it is impossible to engage two different movements simultaneously, thus furnishing a fool-proof control for the rail. Feeding the head vertically and horizontally is controlled by a lever and the desired rate of feed is secured by turning a small hand wheel which is connected with a dial that shows the rate of feed for which the setting has been made. The electric motor, which furnishes these movements, is of 1½-hp. and receives current through a protected trolley that makes contacts with conducting strips fastened to the housing. Either alternating or direct current can be used and, if necessary, it may be taken from a lamp socket. The screws which move the head on the cross rail and the side head on the housing are held stationary and in tension, movement of the heads being accomplished by the rotation of a nut on the screw. A lever is provided for controlling the horizontal feed of the head on the rail or the vertical feed of the tool slide. This vertical movement of the tool slide is also accomplished by revolving a nut around a stationary screw held in tension. Similarly, the screw for elevating and lowering the cross rail is held stationary and in tension. A vertical shaft is employed for transmitting power to the feed mechanism of both the rail head and side head. The transmission gears are so arranged that throwing a lever into two different positions enables the feed to be accomplished either at the end of one cut or just before starting a new cut.

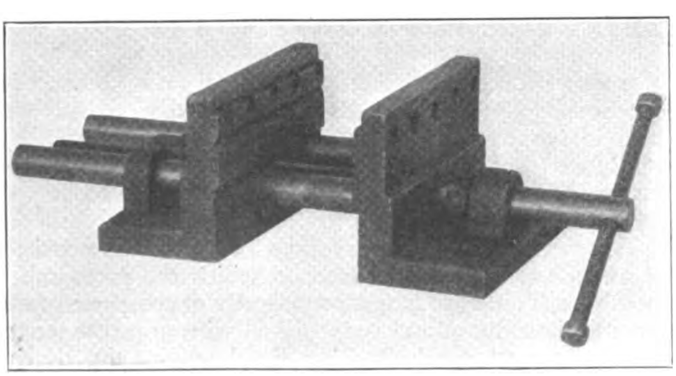
All of the mechanism at the end of the cross rail, that for controlling the feed and power rapid traverse of the side head, and the feed reversing mechanism at the bottom of the housing run in oil. Gages indicate the level of the oil at these points. The housing extends down to the floor and is attached to the bed by means of bolts, fitted into reamed holes. Additional heavy dowel pins eliminate any movement between the housing and the bed. Provision is made for forced feed lubrication, the pump and control valve of this system being located on the outside of the housing. In addition, there is a sight feed attachment which enables the operator to see whether the system is functioning properly. All oil entering the bearings is filtered through a sequence of filtering stations in the bed and then passes through a ½-in. felt wick. The planer bed is twice the length of the table so that the latter never extends beyond the ends. A balanced drive is secured through the use of herringbone gears which eliminate friction and side thrust. These gears are contained in a box cast into the bed to provide for running the gears in a bath of oil.



Liberty open side planer showing compact arrangement of the control levers

A convenient drilling vise

THE D. S. West drilling vise, designed to lighten the work of the machinist, has been placed on the market by the Armstrong Manufacturing Company, Portland, Oregon. The advantages claimed for this vise are its light weight, which is only about one-half that of the ordinary drilling vise; the fact that either jaw forms its own base and may be clamped to the drill press table the other jaw remaining movable, and its ability to hold irregular shapes in almost any conceivable position for drilling.



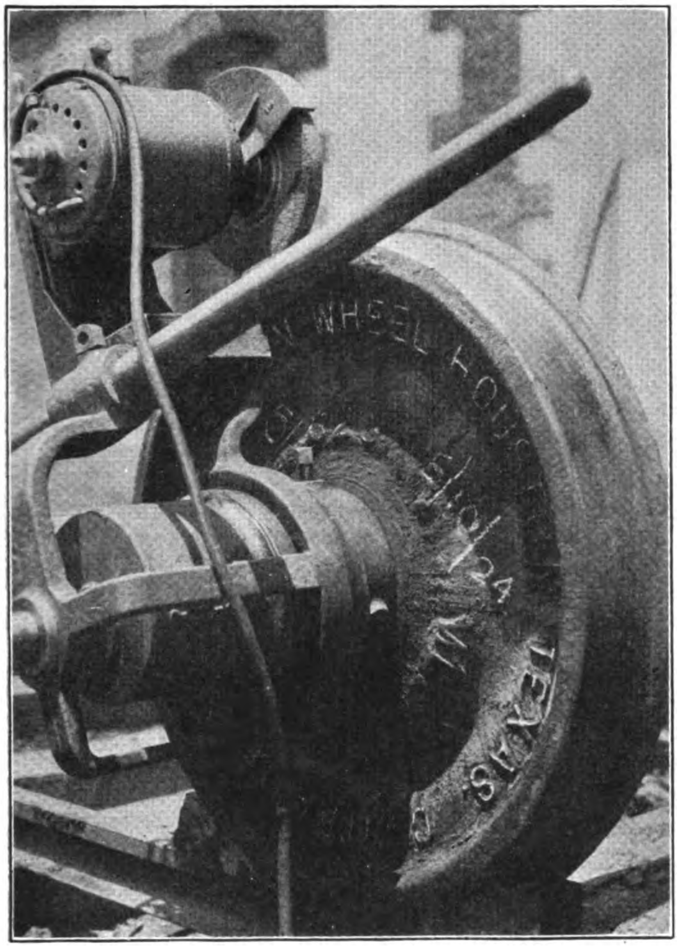
West drilling vise of light weight

The notches machined at the top of the inner edges of the jaws form a rigid support for all kinds of flat and square material, holding such material in a level position so that drilling, tapping or milling may be accomplished. Vertical and horizontal V-grooves are provided for holding round material. Cross rods in combination with the ledges form a base for holding circular, and irregular shapes at any angle for drilling, the cross rods taking the thrust of the drill.

Another feature of the vise is that each jaw is its own base. Either jaw may be clamped down and the unclamped jaw will slide on the drill table. The vise will hold any irregular-shape piece rigidly and will not twist the drill. It is not necessary to block under the work as is the case with many vises.

Castillo portable car wheel grinder

A PORTABLE grinding device has been developed recently for removing the flat spots from car wheels and is being marketed by E. H. Batchelder, Lytton building, Chicago. One of these machines is being used by the Rock Island, one by the Burlington, and five are said to have been in service on the National Railways of Mexico for the past three years reclaiming slid flat wheels with satisfactory results. The machine, which is simple in construction and operation, has the effect of prolonging the life of car wheels. It is driven by a one-horsepower electric motor, weighs about 300 lb., and can be operated by one man. The relatively small weight and cost of this machine, make it especially adaptable to use at rip tracks where the limited number of wheels handled would not justify installing a heavy stationary grinder.



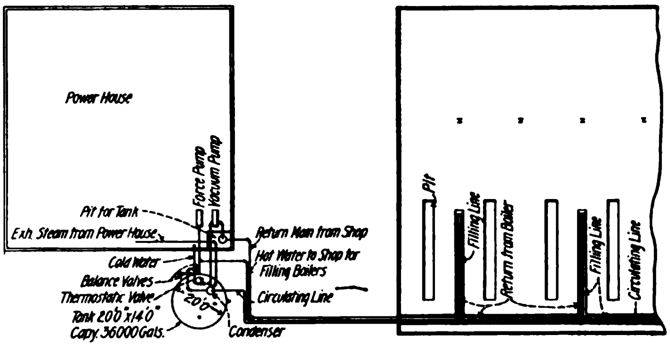
Castillo portable wheel grinder

Referring to the illustration, the construction of the grinder will be evident. The abrasive wheel, driven by special electric motor, is mounted on a cast steel frame capable of a reciprocating, rotary motion about a housing, located centrally with regard to the axle journal and securely fastened to it by set screws. The center of oscillation of the abrasive wheel and steel frame is slightly below the actual center of the axle so that the abrasive wheel moves on an arc larger in radius than that of the car wheel circumference. The effect of the grinder is therefore to spread the flat spot over an arc from 14 in. to 20 in. long depending on the length and depth of the flat spot. The abrasive wheel has lateral movement across the wheel tread by slippage of the cast steel frame on the housing, and radial movement by a feed screw. The tread taper is taken care of by hand adjustment of the feed screw.

Reference to this machine installed on the Rock Island was made at the Mechanical Division proceedings in June, it being stated that 12 pairs of wheels were ground with the machine in 251 min., or an average of 21 min. per wheel, and at a cost of 40 cents per wheel, which did not include the electric current or shop pro rata. The flat spots varied in length between 2½ in. and 3 in. and the metal removed ranged from 3/64 in. to 1/16 in. deep. All of the wheels thus ground were restored to service on the Rock Island equipment and have given satisfactory service since. A careful check of their concentricity indicated that they were not more out of round than is found to be the case with the great majority of new wheels.

Locomotive hot water hydrostatic testing plant

THE accompanying illustration shows a hot water testing plant for back shops or boiler shops where a number of locomotive boilers are tested daily. This work is generally done by filling the boiler with a hot water injector which takes live steam and a good deal of it. One boiler is often tested several times making a large waste of hot water, and as this water runs into a pit it produces a great deal of vapor in the shop. The plant shown has a large receiving and supply tank and a high pressure pump on the discharge line. The discharge line is run below the floor with a connection to each pit. At the far end of the discharge line a circulating line returns to the tank. The pump moves constantly, just enough to keep up the circulation. As soon as the locomotive boiler is connected to the main and the valve is opened, the pump goes to work and will flow any amount required, usually between 300 and 400 gallons per minute so that the boiler is rapidly filled with water at a predetermined temperature. The pump may be so set that it will furnish the required pressure and when it gets to that point it will slow down, or the boiler can be filled and the pressure put on with a hand pump. As soon as the defects have



Piping arrangement of the National automatic, hot water hydrostatic testing plant for locomotives

been chalked the boiler is disconnected from the discharge line and connected to the return line through which the boiler is emptied.

The return line is also below the floor with a connection to each pit. Near the far end it runs through a small regulating tank and from there through a vacuum pump to the main reservoir. The pump is governed by an outfloat on the regulating tank. When a boiler is connected this tank fills up and, through the float, opens the steam line to the pump. When the boiler is empty the pump lowers the water in the regulating tank and shuts off the steam, stopping the pump. The whole arrangement is automatic. A supply of hot water at a fixed temperature is always available. The temperature of the main tank and the height of the water is automatically governed.

This equipment is built by the National Boiler Washing Company, Chicago.

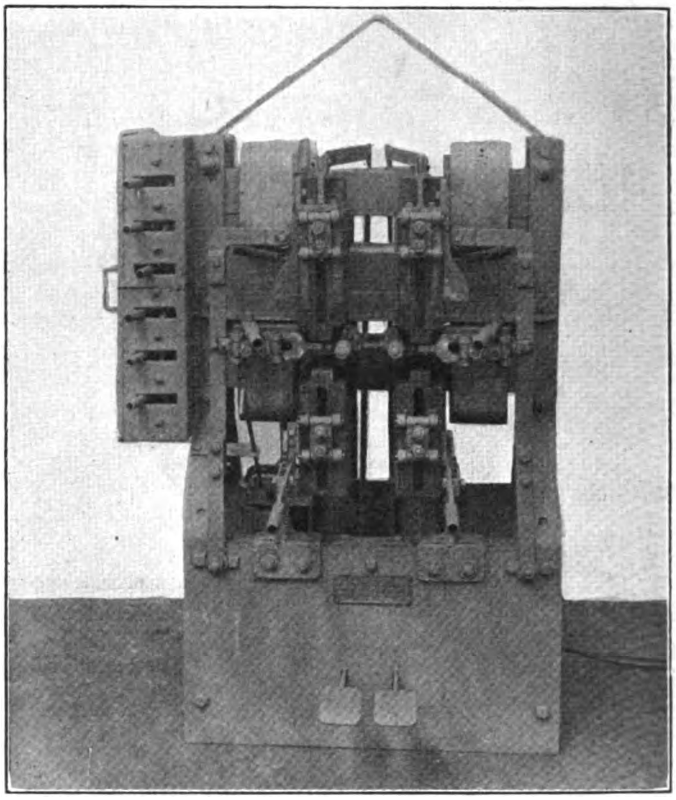
Electric rivet heater for the boiler shop

THREE models of electric rivet heaters, all of which operate on alternating current of any voltage, have been placed on the market by the American Hoist & Derrick Company, St. Paul, Minn. Model A is a two-rivet machine with a 40-ft. super-service table, and weighs approximately 1,100 lb. Model B is a four-rivet stationary type which weighs approximately 1,900 lb. These models are primarily designed for heating rivets for structural work. Model C is a two-rivet machine, especially designed for heating rivets for boiler work. It weighs, ready for service, approximately 2,500 lb.

Model C is equipped with special adjustable side contacts so arranged that the temperature in any part of the rivet may be regulated by the operator. This arrangement enables the operator to heat the grip of the rivet to a white heat, while the end and head are kept at the proper temperature for driving, thus insuring that the rivet completely fills the holes.

The sliding jaws and the E element are of solid cast copper throughout and have thirty times the current carrying capacity of a 1-in. rivet, making it impossible to overheat the machine to a dangerous degree. They are so designed that the rivets up to and including 9 in. in length can be placed in the jaws without any adjustment and with no fear of mushrooming. The sliding jaw permits the E element to be constructed in such a manner as to tightly hug the laminated iron case—its source of power—on three sides, thus practically eliminating magnetic losses and reducing current consumption to a minimum.

All three types are equipped with interlocking heat control, conveniently located at the operator's left hand, which provides instant control of the current. This feature is essential for the proper heating of rivets.



Two-rivet electric rivet heater for the boiler shop

Multiple recording pyrometer

A RECORDING pyrometer which combines accuracy, with other desirable features, has been developed by the Brown Instrument Company, Philadelphia, Pa. The recorder has a die cast black enameled aluminum case. The dimensions are 15 in. high, 14 in. wide and 9 in. deep, requiring a minimum amount of wall space when using a chart 7 in. wide. The instrument is built to make a single record, a duplex record with two records side by side, or in multiple form produces as many as 12 records on one chart.

It operates on the frictionless principle in which a pointer swings freely and at intervals of every 30 sec. is depressed on a carbon or inked ribbon producing a mark on the chart. These marks are so close together as to form a continuous line. The marking ribbon and chart last two months before renewal is required and no inking is necessary. The marking ribbon is above the paper so that the mark is produced on the front side of the paper where it shows clearly. The marking ribbon in the single and duplex recorder, after each mark on the chart, is moved back disclosing the last impression so that the record is clearly visible immediately after it is produced.

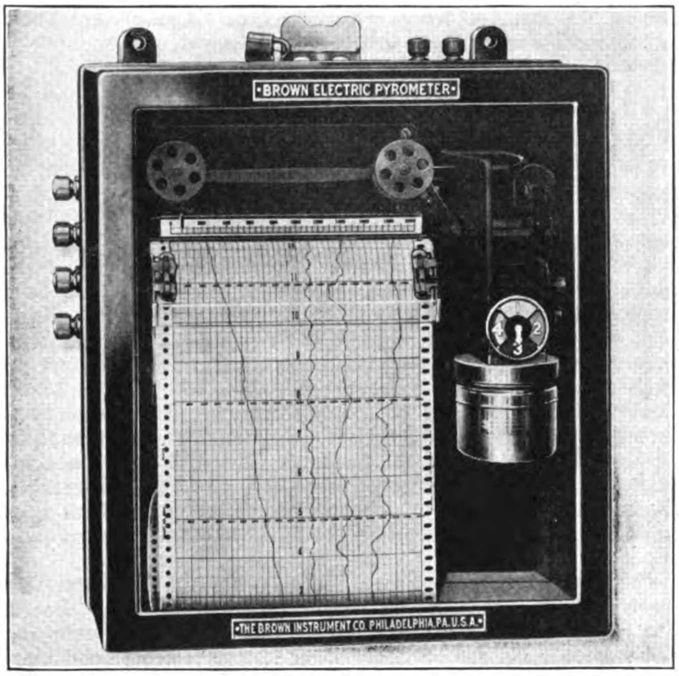
A glass knife edge for tearing off the paper is located directly below the driving roll. The paper can be torn off two hours after the last impression is made.

The galvanometer and the recording chart mechanism is carried on a hinged frame. When swung aside, the galvanometer is instantly accessible, and when closed a housing protects it.

In addition to recording the temperature on the chart, an indicating scale is provided with large figures legible at a considerable distance. The chart has rectangular co-

ordinates. The time lines are straight across the chart and not curved. The recorder is driven by an electric clock if alternating current is available. Six recorders only consume the current required by a 25-watt incandescent lamp. The electric clock eliminates hand winding and no governor or other means is needed to secure accurate timing. Where alternating current is not available, a hand wound clock can be supplied.

The chart speed can readily be changed and is supplied



The chart of the Brown recording pyrometer can be easily read

for a number of combinations. The standard chart speed is one inch an hour but by reversing two gears, a speed of four inches per hour is obtainable. Speed combinations are available from ¼-in. an hour to 6-in. an hour.

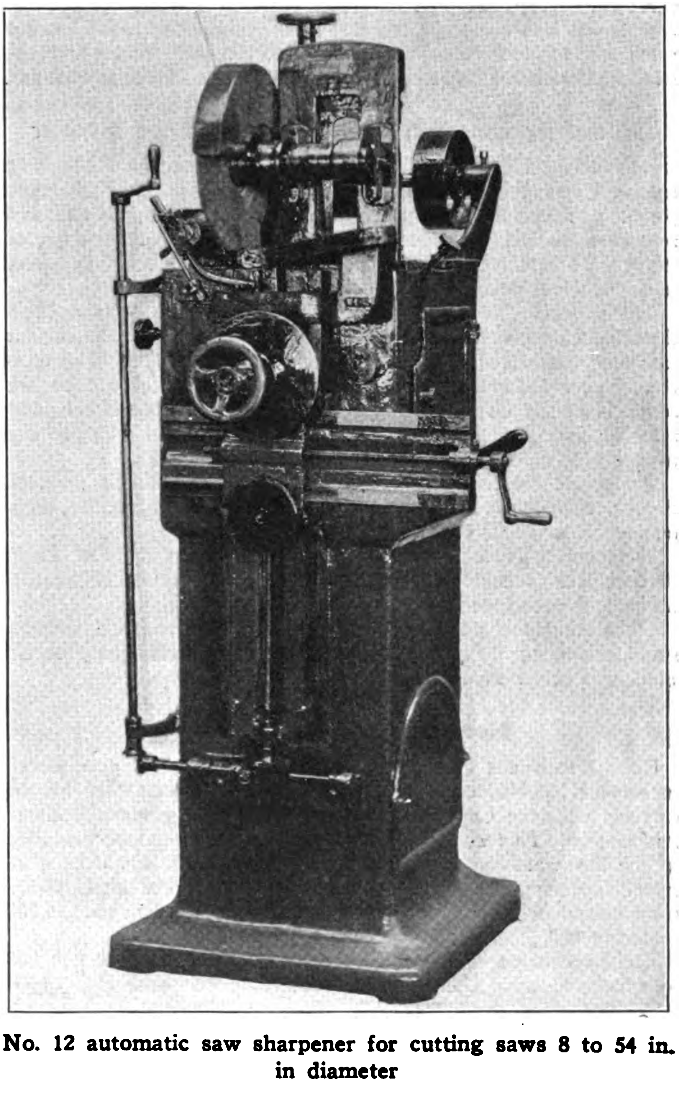
The instrument, as a pyrometer, incorporates an automatic cold junction compensation including the Brown patented index for adjusting a compensated pyrometer to the correct initial starting point on an open circuit.

As a multiple recorder, this instrument incorporates an automatic switch with gold contacts mounted on bakelite and immersed in oil, which prevents any possibility of tarnishing of the contacts from corrosive gases in the atmosphere. The multiple recorder switch includes a dial with an index for indicating the number of the thermocouple or furnace which is being recorded at the time. The record lines are made in different color combinations on the chart and the switch dial is numbered and colored to correspond.

Automatic circular saw sharpener

NOS. 11 and 12 circular saw sharpeners manufactured by the Machinery Company of America, Big Rapids, Mich., embody a type of grinder construction for automatically sharpening, gumming and retoothing medium sized metal cutting saws from 8 to 20 and 8 to 54 in. in diameter. These machines are automatic in their movements and when adjusted to the saw to be retoothed or sharpened may be put in operation and left practically unattended until the work is completed—the saw teeth perfectly sharpened, new teeth cut in if desired, and the saw ready for service. These results are obtained whether the saw is only slightly worn or dulled or is badly damaged. When automatically sharpening the teeth of a dull saw or in grinding in entirely new teeth, these machines will back off the teeth on the same principle as a milling cutter, thereby making a stronger tooth and one that will cut faster than the ordinary V-shape tooth.

The machines are equipped with an index feed so that the feeding and grinding of the saw teeth will not be subject to any unevenness from any uneven, worn or broken condition of the teeth to be ground. With the index feed, perfect sharpening and grinding of the teeth is insured regardless of the condition of the teeth to be ground. Thus, a blank steel plate with no sign of teeth remaining or with broken remnants of teeth will be taken by one of these machines and automatically made into a saw with correct teeth of any desired shape and spacing. This work will be done automatically with no attention from the operator from the time the blank steel plate is placed



No. 12 automatic saw sharpener for cutting saws 8 to 54 in. in diameter

on the machine until it is ready to be taken off as a completed saw, further than an occasional dressing of the grinding wheel or turn of the handwheel to adjust the grinding wheel closer to the work.

The machines are fully automatic throughout, with a heavy solid cabinet frame construction, compact and rigidly supported, with the main working parts (aside from the grinding wheel head and drive pulleys) entirely enclosed in the body, fully protected from all dust, dirt and other foreign matter. The main working parts are provided with ample adjustments for taking up wear and insuring accuracy of action and durable service.

General News

Wage statistics for July

Class I railroads reported to the Interstate Commerce Commission a total of 1.795,669 employees for the month of July, 1925, an increase of 13,973 over the returns for the previous month. The total compensation increased $5,641,770, or 2.4 per cent. The difference in the percentage increase in employment and compensation is due to an increase in the average number of hours worked per employee. Compared with last year, employment shows an increase of 1.3 per cent, while the total compensation increased 3.9 per cent. The percentage difference between the employment and compensation is due to an increase in the number of hours worked per employee coupled with an increase of 5 mills in the average straight time hourly earnings, and 9 mills in the overtime earnings.

Oil-burner runs 3,700 miles with but one layover

Locomotive No. 2517, of the Great Northern, a new oil-burning engine, Class P-2, on Wednesday morning, September 30, completed a round-trip, Seattle, Wash., to St. Paul, Minn., and return—a total distance of 3,571 miles—in less than five days, or 99 hrs. 51 min. Thirteen different enginemen, each way, were successively in charge.

The eastbound train was a special, consisting of 19 cars, 18 of them loaded with silk; and the westbound was No. 27, the regular fast mail, scheduled to run through in 47 hrs. 30 min. The eastbound run, 52 hrs. 25 min., was five hours shorter than the schedule of the Oriental Limited, and on the westbound considerable lost time was made up. With the 19-car train a helper was used for 18 miles ascending the Rocky Mountains.

Eastbound the train left Seattle at 4:30 p. m., Pacific time, on Friday, September 25, and arrived at St. Paul on Sunday, September 27, at 10:55 p. m., Central time.

Westbound, Train 27 left St. Paul on Monday morning about 20 min. late (scheduled to leave at 8:45), and arrived at Seattle, Monday morning on time (6:15 a. m., Pacific time).

Calculating the distance at 3,600 miles, the average rate of speed, including the nine or ten hours in the roundhouse at St. Paul, was better than 32 miles an hour.

New cars and locomotives

Class I railroads during the first eight months this year placed in service 105,446 freight cars, according to reports filed by the carriers with the Car Service Division of the American Railway Association. This was an increase of 490 over the number installed in the corresponding period last year but 10,671 less than were installed during the same period in 1923. Of the total, 11,577 were placed in service in August, including 3,519 box cars, 6,730 coal cars and 269 refrigerator cars.

Freight cars on order on September 1 this year totaled 20,863 as compared with 41,476 on the same date last year and 72,906 in 1923.

Class I railroads during the first eight months in 1925 also placed in service 1,213 steam locomotives, as compared with 1,497 during the same period last year and 2,583 during the corresponding period in 1923. The same roads on September 1, 1925, had 193 locomotives on order, compared with 324 on the same day last year and 1,517 two years ago. During the month of August, this year, 147 locomotives were installed in service. These figures include new, rebuilt and leased equipment.

Strike of enginemen and firemen on the Western Maryland

The enginemen and firemen of the Western Maryland went on strike on October 15, 1925. The movement is said to be participated in by between 400 and 500 men, but it appears that complete passenger train service is being maintained and the officers of the road declare that a considerable percentage of the freight traffic is being moved. Published statements give little information about the real details of the difference between employer and employees, but an increase of five per cent in wages, said to be necessary to make the rates correspond to those which have been adopted by the New York Central Lines, appears to be the main point of dissension. The dispute was taken up by the Railroad Labor Board on its own motion on October 16. On October 21 the Labor Board directed the company and leaders of the brotherhoods to resume the conferences, looking to the termination of the strike, declaring that both sides ought to make concessions. This action of the Board was unanimous.

The officers of the company denied the public statement that the road had disobeyed an order of the Railroad Labor Board. The road has asked the Labor Board to dismiss the case asserting that service is not suffering, passenger service is being maintained 100 per cent and freight service approaching this ratio. This motion has been taken in advisement.

Lackawanna purchases new shop equipment

The Delaware, Lackawanna & Western has purchased the following new machine tools for which the installation has recently been completed in its various shops:

SECAUCUS, N. J., CAR SHOP
- Iron frame standard rip saw and table.

KINGSLAND, N. J., LOCOMOTIVE SHOP
- Tilting reverberatory melting furnace.
- Superheater pneumatic flue welding machine.
- Flue welding furnace for preheating and welding superheater tubes.
- Combination hot saw and tube expander.

SCRANTON, PA., LOCOMOTIVE SHOP
- 90-in. locomotive axle journal turning lathe.
- 86-in. heavy duty face grinder.
- 11-in. by 5-ft. heavy duty lathe.
- 72-in. plain right line radial drill.
- 16-in. by 40-in. by 120-in. piston rod grinder.
- Flat turret lathe.
- Drill grinding machine.
- Universal and tool grinding machine.
- 32-in. heavy duty shaper.
- Universal saw bench.
- 4-in. pipe threading and cutting machine.
- Blacksmith hammer.
- Universal grinding machine.

SCRANTON, PA., ENGINEHOUSE
- Electric arc welder, portable type.

HAMPTON, PA. (SCRANTON, PA.), ENGINEHOUSE
- Single spindle high speed sensitive drill press.

KINGSTON, PA., ENGINEHOUSE
- 50-ton vertical hydraulic forcing, bushing and bending press.

KEYSER VALLEY (SCRANTON, PA.), CAR SHOP
- Single spindle high speed sensitive drill press.
- 2-spindle friezing and shaping machine.

Locomotive repair situation

Date, 1925	No. locomotives on line	No. serviceable	No. stored serviceable	No. req. classified repairs	Per cent	No. req. running repairs	Per cent	Total req. repairs	Per cent

September 1	63,812	53,261	5,902	5,514	8.6	5,037	7.9	10,551	16.5

Data from Car Service Division reports.

48-in. by 21-in. compression type pneumatic yoke riveter.
4-in. heading, upsetting and forging machine.
Blue-printing machine.
Power brake.
Power shear.
Car type annealing furnace.

East Buffalo, N. Y., Locomotive Shops
60-in. by 60-in. by 12-ft. metal planer.
2¼-in. by 24-in. flat turret lathe.
84-in. heavy vertical boring and turning mill.
62-in. horizontal boring and drilling machine.
36-in. heavy duty, new type railroad draw-cut shaper.
11-in. by 5-ft. heavy duty lathe.

Gravel Place, Pa., Enginehouse
12½-ton locomotive crane.

All of these machine tools are motor driven and are provided with push button control.

The 90-in. journal turning and quartering machine installed in the locomotive shops at Scranton is equipped with a counterbalancing device which permits the counterbalancing of wheels in the lathe with little effort and insures accuracy in the turning of journals. This machine is also equipped to turn journals on main crank axles for three-cylinder locomotives and for quartering driving wheels for both two and three-cylinder locomotives. It is estimated that a machine of this type will handle the work of a locomotive shop which has an output of approximately 30 locomotives a month and keep up with the production of the other departments. The 36-in. draw-cut shaper installed in the erecting shop at East Buffalo is a heavy production machine and was secured for machining the back and front end main rod brasses, planing shoes and wedges after being laid out and for slotting and planing cast steel driving boxes. It is expected that this machine, which has been assigned to this special work, will secure increased production due to its high power and adaptability for this particular class of work.

Meetings and Conventions

Tentative program announced for the annual meeting of the A. S. M. E.

A tentative program has been arranged for the annual meeting of the American Society of Mechanical Engineers which is to be held at the Engineering Societies building, 29 West Thirty-ninth street, New York, November 30 to December 4, 1925. The sessions begin at 9:30 a. m. on Monday, November 30, with a meeting of the council followed by a conference of the delegates from the local sections. At 2 p. m. the council and local sections delegates reconvene, and there is also scheduled a meeting of the main Committee on Power Test Codes. An open house for all in attendance at the convention is scheduled for that evening.

The program contains a number of subjects which will be of special interest to railway mechanical department officers. The Railroad Division meets on Tuesday, December 1, at 2 p. m., at which time there will be papers presented on locomotive boilers and on car design, the authors of which are yet to be announced. Sessions of interest to mechanical engineers engaged in railroad work are given in the tentative program as follows:

Tuesday, December 1

9:30 a. m.—Oil and Gas Power Division
Machine Shop Practice Division (I)
2:00 p. m.—Railroad Division
4:30 p. m.—Henry Robinson Towne lecture on engineering and economics, by the Hon. Herbert Hoover
Evening—Award of honorary memberships to the Hon. Herbert Hoover and Worcester R. Warner, past president, A. S. M. E.
Presidential address and reception

Wednesday, December 2

9:30 a. m.—Industrial Furnaces (Fuels Division)
Materials Handling Division
Machine Shop Practice Division (II)
Springs (Special Research Committee on Metal Springs)
Luncheon of council and student branch delegates
2:00 p. m.—General
Annual report of council
Award of Charles T. Main, junior and student prizes
Report of A. S. M. E. investigation for S. P. E. E. on mechanical engineering education
Progress reports of A. S. M. E. professional division
Education and training for the industries of non-college type (Committee on Education and Training for the Industries)
Steam tables research
Student branch conference
Ladies tea and reception
Evening—Annual dinner at Hotel Astor

Thursday, December 3

9:30 a. m.—Steam power (Power Division)
Management Division
Aeronautic Division
2:00 p. m.—Power Plant Materials (Power Division)
Industrial Psychology
Lubrication (Special Research Committee on Lubrication)
Robert Henry Thurston lecture on engineering and science, by Dr. Zay Jeffries
Evening—National Defense Division

Friday, December 4

Council and committee meetings
Excursions

Power and mechanical engineering exposition

The fourth national exposition of Power & Mechanical Engineering will open at 2 p. m. on Monday, November 30, at the Grand Central Palace, New York City, and will extend through the week ending December 5. The basic purpose of the exposition is to bring together showings of manufacturers of power and mechanical equipment so that engineers and industrial executives may have an opportunity for comparative study of the outstanding developments in the field. Devices to increase the effectiveness and economy of combustion and machine tools and equipment used in machine shop practice will be main features of the exhibit.

Freight car repair situation

1925	Number freight cars on line	Cars awaiting repairs: Heavy	Light	Total	Per cent of cars awaiting repairs
January 1	2,293,487	143,962	47,017	190,979	8.3

Data from Car Service Division Reports.

June Mechanical convention

After a joint meeting of the General Committee of Division V—Mechanical, American Railway Association, and the executive committee of the Railway Supply Manufacturers' Association, held in Philadelphia, October 13, it was decided to hold the annual convention of Division V and the R. S. M. A. exhibit on Young's Million Dollar Pier at Atlantic City, N. J., June 9-16, inclusive. In all probability Division VI—Purchases and Stores, A. R. A., will hold its annual convention at Atlantic City at the same time.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs.

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

American Railway Association, Division V.—Mechanical—V. R. Hawthorne, 431 South Dearborn St., Chicago. Next meeting June 9-16, inclusive, Young's Million Dollar Pier, Atlantic City, N. J.

Division V.—Equipment Painting Section.—V. R. Hawthorne, Chicago.

Division VI.—Purchases and Stores.—W. J. Farrell, 30 Vesey St., New York.

American Railway Tool Foremen's Association.—G. G. Macina, 11402 Calumet Ave., Chicago.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York. Railroad Division, A. F. Steubing, Bradford Corp., 25 West Forty-third St., New York.

American Society for Steel Treating.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio.

American Society for Testing Materials.—C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago, Ill.

Canadian Railway Club.—C. R. Crook, 129 Charron St., Montreal, Que. Regular meetings second Tuesday in each month, except June, July and August, at Windsor Hotel, Montreal, Que. Next meeting, November 10. Paper on Analysis of Shop Output and Costs will be presented by J. W. Kennedy, general supervisor production department, Canadian Pacific, Montreal.

Car Foremen's Association of Chicago.—Aaron Kline, 626 N. Pine Ave., Chicago, Ill. Meeting second Monday in month, except June, July and August, Great Northern Hotel, Chicago, Ill.

Car Foremen's Association of St. Louis.—R. E. Giger, 721 North 23rd St., E. St. Louis, Ill. Meetings, first Tuesday in month, except June, July and August, at the American Hotel Annex, St. Louis.

Car Foremen's Club of Los Angeles.—J. W. Krause, 514 East Eighth St. Los Angeles, Cal. Meeting second Friday of each month in the Pacific Electric Club Building, Los Angeles, Cal.

Central Railway Club.—H. D. Vought, 26 Cortlandt St., New York, N. Y. Regular meetings, second Thursday each month, Hotel Statler, Buffalo, N. Y. Next meeting, November 12. Paper on main tracking of freight trains will be presented by D. W. Dinan, assistant general manager of the New York Central, Syracuse, N. Y.

Chief Interchange Car Inspectors' and Car Foremen's Association.—A. S. Sternberg, Belt Railway, Clearing Station, Chicago.

Cincinnati Railway Club.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meetings, second Tuesday, February, May, September and November. Next meeting November 18. Paper on General Railroad conditions will be read by C. A. Radford, publicity agent, Big Four Route. Annual meeting, election of officers and turkey dinner.

Cleveland Steam Railway Club.—F. L. Frericks, 14416 Adler Ave., Cleveland, Ohio. Meetings first Monday each month except July, August and September, at Hotel Cleveland, Public Square, Cleveland.

International Railroad Master Blacksmiths' Association.—W. J. Mayer, Michigan Central, 2347 Clark Ave., Detroit, Mich.

International Railway Fuel Association.—J. B. Hutchison, 1809 Capitol Ave., Omaha, Neb. Next meeting May 11-14, 1926, Hotel Sherman, Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabash Ave., Winona, Minn.

Master Boilermakers' Association.—Harry D. Vought, 26 Cortlandt St., New York. Next Meeting May 25-28, 1926, Hotel Statler, Buffalo, N. Y.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meeting second Tuesday in month, except June, July, August and September. Copley-Plaza Hotel, Boston, Mass. Next meeting November 10. Paper on Activities of the American Railway Engineering Association will be presented by J. E. Armstrong, assistant engineer, Canadian National.

New York Railroad Club.—H. D. Vought, 26 Cortlandt St., New York. Meeting third Friday each month, except June, July and August, at 29 West Thirty-ninth St., New York.

Niagara Frontier Car Men's Association.—George A. J. Hochgreb, 625 Brisbane Building, Buffalo, N. Y. Regular meetings, January, March, May, September and October.

Pacific Railway Club.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Regular meetings, second Thursday of each month in San Francisco and Oakland, Cal., alternately. Next meeting November 12 at Hotel Oakland, Oakland. Associate members night. Papers on the relation of the supply industry to the roads, selling the railroads and the service of the service engineer will be presented.

Railway Club of Greenville.—F. D. Castor, clerk, maintenance of way department, Bessemer & Lake Erie, Greenville, Pa. Meeting last Friday of each month, except June, July and August.

Railway Club of Pittsburgh.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Regular meeting fourth Thursday in month, except June, July and August. Fort Pitt Hotel, Pittsburgh, Pa.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, second Friday in each month, except June, July and August.

Southeastern Carmen's Interchange Association.—J. E. Rubley, Southern Railway shops, Atlanta, Ga.

Traveling Engineers' Association.—W. O. Thompson, 1177 East Ninety-eighth St., Cleveland, Ohio.

Western Railway Club.—Bruce V. Crandall, 226 W. Jackson Blvd., Chicago. Regular meetings, third Monday in each month, except June, July and August.

Supply Trade Notes

The Southern Wheel Company, Pittsburgh, Pa., is contemplating the construction of a plant in St. Louis, Mo.

V. B. Emrick has been appointed a representative of the Locomotive Stoker Company, with headquarters at Chicago.

The Harnischfeger Corporation, Milwaukee, Wis., plans the construction of an addition to its plant at 38th street and National avenue.

J. P. Carney, for the past 13 years general car inspector of the Michigan Central, with headquarters at Detroit, Mich., has joined the sales force of the Grip Nut Company.

C. W. Owsley has been appointed district manager, railway department, at New York, of the E. I. du Pont de Nemours & Co., Inc., in the paint and varnish division, specializing in the Duco products.

The General American Tank Car Corporation, Chicago, has established southern sales offices in New Orleans, La., at 1022 Union Indemnity building, in charge of Z. R. Simon, southern sales manager.

A. A. Helwig, superintendent car department of the Kansas City Terminal, has joined the sales organization of the Bradford Corporation, New York. Mr. Helwig will have his headquarters at St. Louis, Mo.

Joseph T. Ryerson & Son, Chicago, has acquired full rights covering the manufacture and sale of the horizontal drilling and boring machines heretofore manufactured and sold by the Harnischfeger Corporation, Milwaukee, Wis.

The Boss Bolt & Nut Works Division of the Hoopes & Townsend Corporation, Philadelphia, Pa., has been organized through the consolidation of the American Bolt Corporation, New York, and the Hoopes & Townsend Company, Philadelphia.

The Standard Steel Car Company has awarded a general contract to the Austin Company, Cleveland, Ohio, for a one-story addition, 80 ft. by 335 ft., and improvements to its present shop at Hammond, Ind., to cost approximately $200,000 with equipment.

G. R. Ingersoll, of the Associated Materials Company, with officers at 935 Schofield building, Cleveland, Ohio, has been appointed representative of the Morton Manufacturing Company, Chicago, to handle the sale of this company's products throughout the Cleveland district.

E. Thomann, managing director of the railroad department of Brown, Boveri & Co., Ltd., of Baden, Switzerland, and A. Buchli, executive director of the Swiss Locomotive Works, at Winterthur, affiliated with the former company, have arrived in this country to inspect various systems of railroad electrification in operation here. The Brown Boveri Company expects soon to enter actively into the manufacture in America of electrical equipment, including electric locomotives, through an American company now in process of organization.

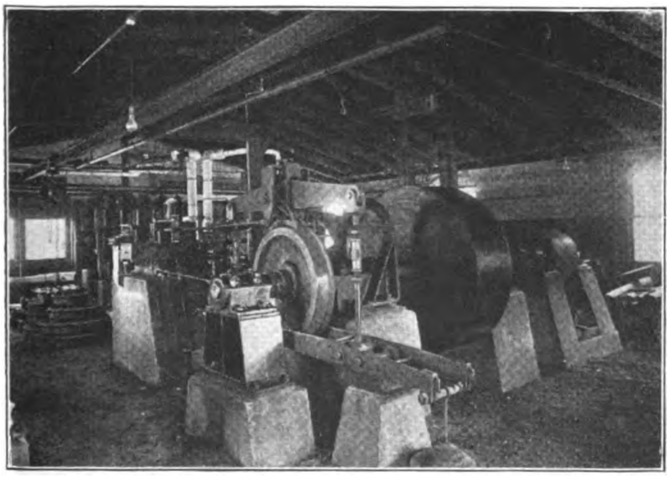
The Air Preheater Corporation, 25 Broadway, New York, manufacturers of the Ljungstrom Air Preheater, is a consolidation of James Howden & Co. of America, Inc., and the Ljungstrom interests of Stockholm, Sweden. The newly formed corporation takes over all Ljungstrom patent rights of the preheater, together with the shops of James Howden & Co. of America, Inc., at Wellsville, N. Y. B. G. Brolinson has been elected president of the Air Preheater Corporation. W. L. Batt, president of S K F Industries, is chairman of the board of directors.

J. H. Williams & Co., Buffalo, N. Y., has just introduced a new line of wrenches made from chrome-molybdenum steel. These tools, known as the Superrench, will supplement the Superior drop forged wrenches of carbon steel, the chrome-molybdenum steel providing a stronger and tougher material with a decrease in weight impossible of attainment with carbon steel. These tools are available in four styles, all heat treated: Engineers' pattern, double head, 15 deg. angle openings—a wrench with thinner and narrower jaws and of generous length; general

service "S" pattern, long and light with unusual leverage; construction pattern, single head, 15 deg. angle opening; structural pattern, single head, straight opening, offset handle.

At a recent meeting of the board of directors of the Westinghouse Electric & Manufacturing Company, Richard B. Mellon, of Pittsburgh, Pa., was elected a director, to fill the vacancy caused by the death of William McConway. Edward D. Kilburn and Walter S. Rugg were recently elected vice-presidents of the company; Mr. Kilburn and Mr. Rugg have been connected with the Westinghouse company for many years. Vice-president W. S. Rugg will take over the direction of Westinghouse engineering activities and vice-president and general sales manager E. D. Kilburn will direct the sales activities as arranged by F. A. Merrick, vice-president and general manager. Mr. Kilburn retains his office of vice-president of the Westinghouse Electric International Company. H. D. Shute, vice-president, will retain his direction of the commercial activities of the company including especially customer relationships, and H. P. Davis, vice-president, formerly in charge of engineering and manufacturing activities as applying to the strictly electrical portions of the company's business, will in future have direction over the entire manufacturing activities of the company and of the general features of the radio business including broadcasting. The duties of the other vice-presidents of the company remain unchanged.

The American Foreign Sales Corporation, a recent incorporation with office at 150 Broadway, New York City, has elected W. G. Kaylor president, and G. A. Smith secretary and treasurer. The directors include the two officers above and F. A. Schaff, vice-president of the Superheater Company; C. S. Sale, executive department, American Car & Foundry Company; Rodney Hitt, of Hitt, Farwell & Company, and Samuel A. Pleasants, of Marvin & Pleasants. The company was organized to promote the sale in foreign markets of American products and is well equipped to handle sales in foreign countries of American railway supplies and equipment. W. G. Kaylor was formerly manager for the Orient for the Westinghouse Air Brake Company and associated companies. Mr. Kaylor was born on April 18, 1883, at Indianapolis, Ind., and graduated as a mechanical engineer from Purdue university in the class of 1905. In 1908 he received a masters degree in mechanical engineering from the same university. Shortly after graduation he entered the service of the Westinghouse Air Brake Company as a special apprentice at Wilmerding, Pa. He subsequently was engaged in installing air brakes on the New York Central's all-steel passenger cars. In 1907 he was instructor of motormen and engineers in the operation of electrified cars and locomotives on the New York Central and the New York, New Haven & Hartford operating out of New York City. In 1911 he was engaged in commercial engineering work for the Westinghouse Air Brake Company at New York. He also had charge of the company's export department and for about a year represented the company in South America. Subsequently he represented the Air Brake Company and associated companies as manager for the Orient, with office in Tokio, Japan, and served in that capacity until November, 1924.



Brake shoe testing machine in the railway engineering laboratories at the University of Illinois

Trade Publications

Reliance motors.—Ball and roller bearing reliance motors for direct and alternating current are described and illustrated in Bulletin No. 4000 issued by the Reliance Electric & Engineering Company, Cleveland, Ohio.

Leather belting.—A non-technical summary of research on the applications of leather belting as compiled by the Leather Belting Exchange Foundation, Cornell University, has been issued in booklet form by the Chas. A. Schieren Company, New York.

Steel filler rods.—The properties of iron or steel filler rods for both gas and metallic arc welding are described in a 28-page booklet issued by the Chicago Steel & Wire Company, Chicago, Ill. Many questions which have hitherto perplexed those interested in fusion welding are answered in this booklet.

Chucks.—The Union Manufacturing Company, New Britain, Conn., has issued a 64-page illustrated catalogue descriptive of its line of chucks, which includes combination, universal independent, geared scroll, scroll combination, planer, boring mill, car wheel, grinding machine, box body, round body and drill chucks.

Milling cutters.—The Goddard & Goddard Company, Detroit, Mich., has recently brought out a catalogue on milling cutters and their uses, which is devoted exclusively to milling cutters adaptable for use in railroad shop work. Complete descriptions and specifications of the various types of cutters, as well as information pertaining to the particular class of work for which they are designed, is contained in this 96-page catalogue.

Electro-mechanical hammer.—The Kango electro-mechanical hammer, which is of a light chipping, caulking and scaling type, for use on metal, stone, wood or other material, is described and illustrated in a 12-page brochure issued by the Kango Company, Ltd., London, England. This hammer consists of a cylindrical casing fitted at the upper end with a stirrup-shaped handle, through which is led the cable for the motor and in which is situated the trigger switch.

Electric rivet heaters.—American electric rivet heaters and shop appliances are described and illustrated in a 16-page booklet issued by the American Hoist & Derrick Company, St. Paul, Minn. A seven-day comparison of the results obtained with an American electric rivet heater and an ordinary oil furnace appears in the booklet in tabular form, the sizes, numbers of rivets and weights being given, also the current consumption for the electric heater and the oil consumption for the oil heater.

Agathon alloy steels.—The Central Steel Company, Massillon, Ohio, has gotten up a handy disk of celluloid construction for the use of those who are engaged in the heat treatment of alloy steels. By turning the slide on one side of the disk to the grade number, the composition of that particular grade is obtained and also a reference letter referring to the proper treatment is given. By turning the slide on the opposite side of the disk to the reference letter, data as to the proper heat treatment can be obtained.

The four-wheel trailer truck.—Under the title of "The Locomotive Four-Wheel Articulated Back End," the American Arch Company, Inc., New York, has issued an eight-page pamphlet describing the articulated four-wheel trailer truck of the type used under the Lima 2-8-4 type locomotive, first placed in service on the Boston & Albany, and setting forth the advantages of the large grate area the four-wheel truck makes possible in improving combustion and boiler efficiency. The truck is sold under patents controlled by the American Arch Company.

Locomotive superheaters.—The Superheater Company, New York, has issued the fourth edition of its Instruction Book on the locomotive superheater, giving instructions for installation, operation, maintenance and repairs. This book supersedes the edition issued in 1917 and contains 87, 4½-in. by 6-in. pages. It has been completely revised and gives the latest recommendations relative to the installation, operation and maintenance of the Elesco Type A superheater. Questions and answers in the back of the book cover the principle of superheating generally. The subject matter is well supplemented with illustrations.

Personal Mention

Master Mechanics and Road Foremen

H. Y. Harris has been appointed master mechanic of the Seaboard Air Line, with headquarters at Tampa, Fla.

E. J. English has been transferred as master mechanic of the Great Northern at Minot, N. D., to Everett, Wash.

W. A. King has been appointed road foreman of engines of the Seaboard Air Line, with headquarters at Wildwood, Fla.

F. B. Moss has been appointed master mechanic of the Richmond division of the Chesapeake & Ohio, with headquarters at Richmond, Va.

S. G. Clark, formerly traveling engineer of the Great Northern at Havre, Mont., has been promoted to master mechanic, with headquarters at Minot, N. D.

Robert G. McKee has been appointed master mechanic of the Chicago division of the Chesapeake & Ohio, with headquarters at Peru, Ind., succeeding E. R. Woody, who has been transferred to another point and assigned to other duties. Mr. McKee was born on April 20, 1885, at Rockbridge Co., Va. He attended the public schools at Bueno Vista, Va., and on May 1, 1903, entered the employ of the American Locomotive Works as a machinist apprentice. On March 5, 1904, he entered the Seventeenth Street shops of the Chesapeake & Ohio, and on August 5, 1904, was transferred to Clifton Forge, Va., completing his apprenticeship on July 15, 1907. From the latter date until January 1, 1913, he served as machinist and shop draftsman. He then entered the employ of the Baltimore & Ohio as a gang foreman at the Mt. Clare shops, Baltimore, Md., on October 1, 1913, returning to the C. & O. shops at Clifton Forge as shop draftsman and apprentice instructor. On January 20, 1914, he was promoted to gang foreman, and on May 1, 1916, transferred to Peru, Ind., as general foreman. On May 16, 1923, he was transferred to the Huntington shops where he remained until his appointment as noted above.

R. G. McKee

Shop and Enginehouse

L. F. Fife has been promoted to general foreman, motive power department, of the Southern Pacific, with headquarters at Sparks, Nev.

B. F. Madden has been promoted to the position of departmental foreman of the Southern Pacific shops at Sparks, Nev., succeeding L. F. Fife.

William A. Schipper has been promoted to machinist foreman of the Southern Pacific, with headquarters at Sparks, Nev., succeeding B. F. Madden.

J. O. McCann has been appointed boiler foreman of the Chicago & Alton, with headquarters at Slater, Mo.

W. H. Davis, acting night foreman of the Kansas City Southern, at Port Arthur, Tex., has been permanently promoted to that position.

W. H. Dillon has been appointed machine shop foreman of the Chicago & Alton, with headquarters at Slater, Mo.

W. J. Taylor, general foreman of the shops of the Southern Pacific at Sparks, Nev., has been transferred as general foreman to Sacramento, Cal.

J. R. Zeurick, general boiler foreman of the Baltimore & Ohio at the Ivorydale shops of the Baltimore & Ohio at Cincinnati, Ohio, has been promoted to general foreman, with headquarters at Flora, Ill.

Purchasing and Stores

A. N. Warner has been appointed storekeeper of the Great Northern, with headquarters at Breckenridge, Minn.

R. S. Simmons has been appointed storekeeper of the Great Northern, with headquarters at Williston, N. D., succeeding A. N. Warner.

G. F. Ohden has been appointed division storekeeper of the Illinois Central, with headquarters at Water Valley, Miss., succeeding W. E. Hoyt, deceased.

W. L. Wheeler has been appointed assistant general storekeeper of the Chicago & North Western, with headquarters at Chicago, succeeding D. W. Corcoran.

O. A. Donegan has been appointed general storekeeper of the Boston & Maine, with headquarters at Boston, Mass., succeeding J. E. Byron, who has been assigned to other duties.

D. W. Corcoran, assistant general storekeeper of the Chicago & North Western, with headquarters at Chicago, has been promoted to general storekeeper, with the same headquarters, succeeding R. M. Blackburn, who has resigned.

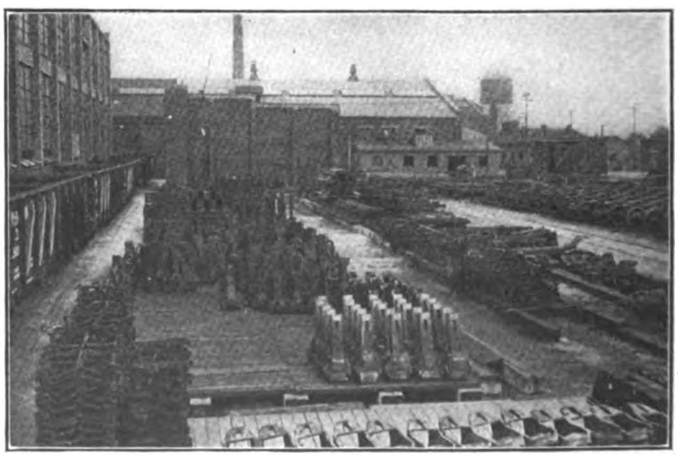
Car Department

F. M. Darden, assistant car foreman of the St. Louis-San Francisco, with headquarters at Springfield, Mo., has been appointed general car foreman of the west freight shop, with the same headquarters, to succeed G. W. Thomas, resigned.

Promotion of Sir Henry Fowler

Sir Henry Fowler, K. B. E., has been promoted from deputy mechanical engineer to chief mechanical engineer of the London, Midland & Scottish Railway, succeeding George Hughes, who retires. The news of Sir Henry Fowler's promotion will be of interest to numerous persons in the United States. During the war he was superintendent of The Royal Aircraft Factories for the British government, and while serving in that position visited the United States. He was a joint general secretary of the recent International Railway Congress in London and was active in making and carrying out the arrangements of the British railways for the entertainment of the foreign visitors.

He was formerly chief mechanical engineer of the Midland Railway and became deputy chief mechanical engineer of the London, Midland & Scottish when the program of amalgamation of British railways was carried out, in accordance with which the London & North Western, Midland and some other lines were consolidated into the London, Midland & Scottish. He has been president of the Institution of Locomotive Engineers, of the Institution of Automobile Engineers and of the University of Birmingham Engineering Society.



Neatly arranged material yard for a car department

M. B. RICHARDSON, *Associate Editor* H. C. WILCOX, *Associate Editor*

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Request for change of address should reach the New York office two weeks before the date of the issue with which it is to go into effect. It is difficult and often impossible to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, be sure to send us your old address as well as the new one.

Subscriptions, including the eight daily editions of the Railway Age published in June, in connection with the annual convention of the American Railway Association, Mechanical Division, payable in advance and postage free: United States, Canada and Mexico, \$3.00 a year; foreign countries, not including daily editions of the Railway Age, \$4.00. When paid through the London office, 34 Victoria Street, S. W. 1, 17s. 0d. Single copy 35 cents or 1.6d.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulation (A. B. C.).

Railway Mechanical Engineer

Vol. 99 | December, 1925 | No. 12

Order your index now

The current volume of the *Railway Mechanical Engineer* closes with this issue. Only a sufficient number of indexes will be printed to supply copies to those of our readers who specifically request that a copy be sent them. If you want the index, therefore, place your order now, mailing it to our New York office, 30 Church street, New York.

Using the Railway Mechanical Engineer

Several preceding issues have contained in these columns suggestions of ways in which the *Railway Mechanical Engineer* may be made useful to mechanical department officers and foremen. These have dealt largely with what may be called organized or group utilization. The greatest value of the paper, however, comes to the individual subscriber whose reading habits lead him to scrutinize each issue as it is received so that he may be sure he has not missed any article dealing with a subject in which he is concerned, before he finally lays it aside. Just to illustrate, have you ever encountered difficulty in the maintenance of old Vanderbilt tanks? This issue tells you how one railroad has overcome this condition. Has the problem of effective staff meetings ever given you concern? In this issue you will find suggestions—in two places—on how not to handle staff meetings as well as on how they have been conducted successfully. Did it ever occur to you that the location of the whistle on the locomotive is a matter of importance? Are you satisfied with the present situation with respect to the transfer of lading from bad order cars? Are you interested in the application of the newly developed lacquer process to passenger coach finish? Is the matter of die construction for forging machines one with which you are concerned? If you are interested in these and many other questions pertaining to mechanical department affairs, do not fail to make full use of the *Railway Mechanical Engineer* by reading what others have accomplished in solving, or have to say concerning, these problems, in this issue.

Getting the most out of power hacksaws

Every machine tool is limited in production by the cutting tools that are used on it. Practically all types of machines have been developed to the maximum feeds and speeds that it is possible to obtain with the cutting tools now on the market. Much greater production could be obtained with practically every machine tool if it were possible to secure tools that would stand up under a heavier cutting schedule. Power hacksaw machines have probably been handicapped more than any other machine tool in this respect, because the manufacturer of hacksaw blades has lagged considerably behind the development of other cutting tools. As a result, some users do not consider the power hacksaw as a machine tool and will not give it the same study and consideration necessary to improve the production possible to obtain from it. In many shops, the cheapest kind of labor is used on these machines. They are not always kept in good repair, nor are they properly cleaned. Furthermore the cutting-off operations of which these machines are capable, are not given the same careful consideration which is given the milling, drilling or grinding machine. The purchase of hacksaw blades is often based on price alone. A careful study of a power hacksaw machine shows that it has many advantages over other types of cutting-off machines. It requires less power, is quicker to operate and requires less time to stop, move up the work and start again; the blade expense is less, it removes a much narrower kerf and the initial investment is much smaller. In the past there have been two objections to a machine of this type which have been overcome during the past two years; namely, blade breakage and crooked cutting. A modern power hacksaw will not break blades as long as the machine is in good condition, provided it is running at the correct number of strokes per minute and that the blades are of the correct specifications for the material being cut. Within the past year, several types of hacksaw blades have been placed on the market which are capable of utilizing the maximum capacity of a modern power hacksaw machine. A modern machine of this type represents a capital investment and should receive the same consideration as any other machine tool, in order that it may earn the greatest possible return. It should be properly maintained and consideration should be given to the selection of the blades which will utilize the capacity of the machine.

Possibilities of standard small tools

A great lack of uniformity exists in the small tools used for similar operations, not only in railroad shops and enginehouses on different railroads, but in the various shops and terminals on the same road. The arguments in favor of a certain amount of standardization of these tools are well known, consisting primarily of reduced cost to manufacture, consequent lower possible selling cost, and reliable products more uniformly adapted to perform the manifold operations in repairing cars and locomotives.

The American Railway Tool Foremen's Association took a step in the right direction at its convention last September when a regularly appointed committee of the association submitted for adoption certain general specifications for standard locomotive frame and rod reamers. The variation in reamer sizes, flute lengths, taper, spiral angle, type of shank, and one or two minor details were specified, and, after some discussion, the association voted to recommend the proposed reamers to the Mechanical

Division for consideration at the Atlantic City convention next June. If adopted as standard by all the roads, the result will be to reduce materially the number of kinds of taper reamers used in railroad shops and enginehouses. The Tool Foremen's Association is to be congratulated on its work in connection with these reamers, particularly in view of the well-known difficulty in getting any body of mechanical men to develop a standard design which will meet satisfactorily the varying needs of all the individual members.

Another tool which is under consideration for standardization by the Tool Foremen's Association at next year's convention is the boiler tap, and the problem of what general specifications to adopt in this case is complicated by the difference of opinion regarding the relative merits of Whitworth and V-type threads for boiler work. It would seem reasonable to assume, however, that one of these threads is in general superior to the other and the better one of the two ought to be adopted on all the railroads in the country. The manufacturers could then increase their production of that particular type of boiler tap and with the use of specialized high production machinery and methods turn it out at decreased cost.

This work of reducing to a certain extent the multitudinous variety of shop tools, and particularly the great number of expensive special tools used by individual roads, may well be encouraged and extended. With judgment in the determination of what tools can be properly standardized without a deadening effect on the development of new and improved tools, it will save the railroads money and prove advantageous to all concerned.

Mechanical department staff meetings

Few, if any, railroads carry out the idea of holding annual mechanical department staff meetings to the extent practiced on the Chicago, Milwaukee & St. Paul, under the direction of L. K. Sillcox, general superintendent of motive power. That the value of the meetings in the way of inspiration, education and the promotion of better feeling and unified action on the part of the mechanical department supervisory officers, more than justifies the effort and cost involved seems to be well established by experience on the St. Paul. In fact, since the inauguration of the staff meeting plan four years ago, the meetings have increased in size and importance, the men working harder each year in preparation for them and being more enthusiastic each year about the results accomplished.

The 1925 staff meetings began with that of the general, blacksmith and tool foremen held at Milwaukee, Wis., June 8 to 10, inclusive, at which 24 papers on selected subjects were read and discussed. Following this meeting within a period of two months, the air brake foremen met for a two-day session and discussed standard practices for the maintenance of air brakes, the meeting being divided as between the locomotive and car departments; traveling engineers from all over the system held a two-day session at which 16 papers were presented; the boiler foremen met in Minneapolis for a three-day session at which 17 papers were presented; the chief clerks, also divided as between the locomotive and car departments, met for a two-day session, in each case considering 10 subjects; the master mechanics held a three-day session, discussing 19 subjects; the car department also held a three-day session at which 20 papers were presented. The last of these meetings was held at Milwaukee, October 12 to 13, at which special apprentices discussed 17 papers pertaining to their work.

The mechanical department officers from the entire system so far as possible, attend these meetings, which are scheduled in such a way that the maximum number of men can be in attendance without interfering with service and the normal functioning of the mechanical department. Mimeographed copies of the papers prepared in advance are available to the members before attending the meetings and this enables a more studied and careful discussion to be maintained. A record of the discussion is kept which also subsequently becomes available to the men interested for further study and guidance in their work during the coming year. Unquestionably, the mechanical department staff meetings as held on the Chicago, Milwaukee & St. Paul, have had a most helpful influence in assisting the mechanical officers to understand their mutual problems better, in improving the acquaintance of these men and welding them into a unit in the furtherance of the better interests of the railroad they serve.

Utilizing shop schedules

Due to the varied nature of locomotive shop work it has always been more or less difficult to compile figures which will serve as a true indicator of shop production or output. To say that a locomotive shop turns out so many classified repairs in a given month is not by any means a sound basis for comparison of output, neither is a comparison of man-hours always a true indicator of production.

Several large locomotive shops in this country have, however, developed systems along with their shop scheduling systems which serve as a reasonably accurate indicator of output. These have been fully described in past issues of the *Railway Mechanical Engineer*, and it is sufficient to point out here that one such system is based on the principle of allotting a certain number of points for each locomotive which has been given classified repairs, the number of points depending, in general, upon the class of repairs, due consideration being given to the type of locomotive and whether repairs in a given class are light or heavy. With this system it is possible to determine the number of man-hours required to make a point, and a comparison of these figures serves to furnish at least a consistent basis of comparison of output.

In one shop using such a system a keen spirit of rivalry became apparent between different gangs which resulted in many original ideas being brought out to save time and labor on many jobs which were formerly done in a less efficient manner. The foremen throughout the shop are periodically furnished with reports showing the progress being made during the month, and in an effort to produce "points" with the least possible number of man-hours, every element of machine and erecting shop practice entering into production is carefully watched. In this manner many machine tools in that shop which had been rendering service for a great number of years were found to be the real reason why it was impossible to make a substantial reduction in man-hours on certain jobs. This led to the making of time studies on such machines in comparison with more modern machines recently installed for the same class of work with the result that those in charge of the shop were able to present to the management some real figures showing why new machine tools should be purchased.

Is it not possible that one of the reasons why many shops must get along with inadequate machine tools is because there has been no systematic effort made to find out just how much could be saved by the installation of more modern tools?

Locomotive shop scheduling systems were originally developed with the idea of increasing output. Some shops which have gone a little farther than others in develop-

ing the details of scheduling systems have found that it is possible to secure reliable data on many phases of shop operation which not only make it easier to perform the ordinary repair work but also furnish a comprehensive basis for the requisition of new machine tools and shop equipment.

Front end draft appliances

Railroad mechanical men don't need to be told that the arrangement of draft appliances in the front end has an important bearing on locomotive performance. Not every one realizes, however, that it is almost impossible to over-emphasize the importance of this feature of locomotive design. The fuel savings made possible by modern locomotive design and the incorporation of various auxiliary fuel economy devices can be completely nullified by improper arrangement of the draft appliances in the locomotive front end.

A striking example of necessity of front end adjustment to suit individual conditions was afforded by the tests of Missouri Pacific three-cylinder Mikado locomotive 1699 at the Altoona test plant, as reported on page 462 of the July, 1925, *Railway Mechanical Engineer*. When this locomotive was placed on the test plant it was believed that with proper combustion an evaporation of 59,000 lb. of water an hour could be obtained, but, on the first trial with a 6¼-in. exhaust tip, the evaporation proved to be only 48,000 lb., or almost 19 per cent less than was expected. The exhaust tip was then increased to 6½ in. and the stack fitted with an extension to within 15 in. of the nozzle. No improvement was obtained with this arrangement. A Pennsylvania Lls stack was then applied with the same 6½-in. exhaust nozzle and a basket bridge, and an evaporation of 46,440 lb. of water an hour obtained. In order to fill the stack, the exhaust nozzle was then increased to 7 in. in diameter, the basket bridge being retained and an evaporation of 55,000 lb. an hour then resulted.

The final change was to use a 7-in. tip with Goodfellow projections, this arrangement bringing the evaporation up to 59,900 lb. an hour and later to 61,680 lb. Retaining the 7-in. tip with Goodfellow projections the original front end arrangement was replaced except for the petticoat pipe and the evaporation immediately dropped.

It is obvious that thorough-going tests must be made to determine what draft arrangement in the front end will produce the best results. Otherwise locomotives will waste fuel probably in sufficient amount to counterbalance anticipated savings from the application of superheaters, feedwater heaters, brick arches, syphons and other fuel saving devices. Not only is it essential that the dimensions, proportions and arrangement of draft appliances in the front end be suited to each particular class and possibly to each locomotive, but steps must be taken to assure that the correct front end arrangement, once established, be maintained.

A master mechanic of a large road was recently asked by his chief what size exhaust tip was being used on a certain class of locomotives handled at his terminal. In reply he stated that it was a 6½-in. tip. The chief asked him if he was sure, and he replied somewhat heatedly in the affirmative. A subsequent check of exhaust tips on eight locomotives of this class indicated that only one had a 6½-in. tip, the exhaust tips on the other locomotives varying from ⅛ in. to ¾ in. in size.

The necessity of giving unceasing attention to the maintenance of draft appliances in locomotive front ends is apparent.

New Books

Principles of machine design. *By C. A. Norman, professor of machine design, Ohio State University. 710 pages, illustrated. 5½ in. by 8½ in. Price $6.50. Published by the Macmillan Company, New York.*

This important addition to books in the engineering field covers somewhat more than the average text book on the subject. It teaches not only how to describe and how to design, but it goes further and contains computations carried through in detail for elements or combinations of elements, forming part of a specified whole, in numerous types of machines. Of the 585 illustrations, many are line drawings and photographs of actual machinery which show clearly not only the general make-up, but also good proportions and assemblies. In addition, there are a number of diagrams illustrating theory and computation. Much detail information and many numerical tables, not generally accessible, are included in the book. These will be found a distinct aid to designers and other engineers desiring this data for reference. For the practicing engineer the book furnishes up-to-date standards with regard to riveting, screws, sprockets, gears, etc., and also gives a collected and fairly simple treatment of modern experience and research, both here and abroad, regarding such matters as wear factors for gears, design of helical gears, belt action, belt loads, laws of lubrication, bearing loads, pressure drop in pipe lines, and other similar problems of design.

What Our Readers Think

The evaporative capacity of locomotive boilers

Philadelphia, Pa.

To the editor:

Our present knowledge of boiler performance must be largely based on empirical data and moreover we are only concerned with such performance for a definite range of operation. From this point of view, simplicity in formula giving a good approximation is the most desirable. On the other hand, aside from mere satisfaction, research or fundamental advance in design demands approaching the phenomena from the most rational basis irrespective of the complications, provided some sicplicity can be obtained in the ultimate results. Considering, however, the flexibility in design as to heating surface, etc. With resulting good efficiencies and the precision of measurements for this kind of work, it is clearly seen that boiler performance at best can only be approximated. Therefore, the degree of refinement in the analysis must keep this concept always in view.

Equation *6* in the first part of Mr. Poperev's article, published in the August issue of the *Railway Mechanical Engineer*, appears logical and his arrangement in the subsequent equations showing the nature of the losses is, all told, a valuable contribution. It is to be noted, however, that various coefficients of the equation are only applicable to one particular boiler of a given type. In the subsequent work, however, Mr. Poperev attempts to correlate these coefficients to account for the various proportions, detail geometrical configurations, types, etc., found in the boilers examined, in the forms of curves or definite functions, the primary variable being the ratio of the heating surface H to grate area G. This is, in my

opinion, exactly the weak spot of his analysis, because there is considerable flexibility in the coefficients proportional to the losses for different ratios of H/G depending upon the configuration and location of the particular percentage of the heating surface, relative firebox volume, etc. It is admitted the ratio H/G is an important constant characterizing the performance of a boiler, provided, of course, boilers of nearly the same configurations are compared. On the other hand, it is equally well recognized that firebox volume to grate surface is of great importance and Mr. Poperev's analysis in no way properly takes this ratio into consideration. Variation in the superheater surface and its configuration in the boiler, the brick arch, length, spacing and diameter of tubes, etc., effect to a more or less degree the efficiency for a given value of H/G. Therefore, the refinement proposed in the analysis is inconsistent with the lack of proper account of the several variables found in the comparison of the various types of boilers.

The formulas proposed by either Dr. Goss or Lawford Fry, appear satisfactory, since they account with sufficient accuracy the performance within the range of operation of locomotives in a much more simple form. Mr. Poperev condemns these formulas, primarily since they do not satisfy limiting conditions, as the initial conditions of zero efficiency at very low rates of combuston, etc. Since, however, we are concerned only with a definite range of operation, it must be admitted, that the simplest equation approximating this particular zone is the most desirable and that a good approximation can be made without necessarily satisfying initial conditions.

Neglecting the error for extremely low rates of combustion which is outside the field of operation, the assumption that the efficiency varies as a linear function of the combustion rate appears sufficiently accurate to account for the actual performance curve of a locomotive boiler. It is to be noted that Mr. Fry's assumption as to the variations of efficiency is in accord with other investigators in the field. Moreover, it would seem that the assumption of a linear function within the range of operating rates of firing is as logical as Mr. Poperev's assumption of a second degree equation for the rate of evaporation to the rate of combustion. Assuming the linear function for efficiency variation, we arrive at a quadratic form for the rate of evaporation to the rate of combustion which satisfactorily accounts for a rate of combustion that may occur within the range of operating firing. With coefficients derived from the efficiency linear equation, the resulting quadratic equation of the evaporation against combustion, fits the actual curves.

Fundamentally, we are concerned with three quantities for estimating and comparing the performance of a locomotive; first, the availability or potentiality of the steam for entrance to the cylinders; second, the efficiency of the card cycle or the cylinder efficiency, and third, finally the efficiency of transference of the heat from the combustion of the coal to the steam in its particular potential form. The latter, the "boiler efficiency," is dependent upon the efficiency of combustion, the magnitude of radiation and the efficiency of heat transference through the tubes. The loss due to combustion, a very important loss, obviously increases with the rate of combustion, but on the other hand, is greatly dependent upon the proportions of the firebox, the proper circulation of air, etc., and probably varying as some inverse function of the volume of the firebox. The radiation in the firebox is of a very uncertain magnitude, some claiming it to be directly proportional to the grate area, others to the firebox surface, etc. It is probably a complex function of both firebox surface, grate area as well as the geometrical configuration and volume of the firebox where in the simple form of the Boltzman Stephan law of radiation must be considerably modified. The availability of heat for transference to the tubes depends at the offset upon the total temperature head of the heated gases and therefore indirectly upon the exact nature of the preceding combustion and radiation phenomena. Then in addition, the heat transmission per unit area of tubes along the tubes depends upon the temperature head for that part, the velocity of the gases through the tubes, the degree of circulation depending upon the spacing of the tubes, etc., and finally on such details as the magnitude of soot, grease, etc., along the tubes. The law of heat transference must be modified for tubes with superheater elements. The cross section area of these to the total tube area is an important ratio for the heat transfer in the tubes.

In conclusion, therefore, it would seem that if a more elaborate method is offered for the analysis of boiler performance, it should consistently be based upon closer physical assumptions, rather than follow the more approximate assumptions used in the older methods which when used in their present forms are sufficiently accurate for the approximate comparisons of performance in which they are ordinarily used. R. Ekserglan,

Engineer and technical assistant to the vice-president, Baldwin Locomotive Works.

Is the A. R. A. overlooking a good bet?

Kansas.

To the editor:

In doing a first-class job of getting along, giving better service than ever thought possible, higher wages, higher material costs, increased taxes and other financial burdens are causing the railroads to economize in every phase of the game. The great forum of railroading, the American Railway Association, has done much to promote efficiency and with its seven divisions, the material and tangible side of the question is most thoroughly covered. The by-laws of the A. R. A. provide for the following divisions and prescribe the duties and limits of each: Division I—Operating; Division II—Transportation; Division III—Traffic; Division IV—Engineering; Division V—Mechanical; Division VI—Purchases and Stores, and Division VII—Freight Claims.

Various railroads have departments for helping those outside their own ranks in an educational way and do this through agricultural and industrial departments with competent specialists. Only a small number of the roads have any sort of training for their own mechanical department employees, or have any officer dealing with the human side of railroading. On the roads where this is being considered, personnel departments are doing the human engineering and regularly constituted apprentice departments through their schools are carrying on the educational work. Personnel work on railroads is a comparatively new idea but apprentice training has been successfully tried and proved over a span of two decades. However, there is no medium through which the heads of these departments can meet and work for general betterment in this respect.

The logical place for such a group is within the A. R. A., which association, if it does not believe the subject large enough for a special division, is overlooking a good bet in not having a standing committee in Division V to work out mechanical department educational and personnel problems, bending an effort towards making the 60 per cent of mechanical department expenditures (for labor) more productive, keeping pace with the improvements along all other lines of the business of transportation. Educator.

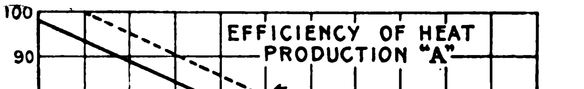
Locomotive test plants—Their influence on design*

Progress made during the past 20 years makes further advance more difficult—Exact knowledge is essential for future development

By Lawford H. Fry
Metallurgical engineer, Standard Steel Works, Burnham, Pa.

No study of locomotive development and operation can be complete without full consideration of the work done by the locomotive testing plant at Altoona, Pa., as the results of this work have materially influenced locomotive design not only in this country, but abroad. W. Rowland is designing locomotive boilers in England by methods developed largely from test data obtained at the Altoona test plant and his formula has been adopted by the Railroad Board of India as a basis for its official method of estimating locomotive boiler evaporative capacity.

It is possible on a modern testing plant to operate any given locomotive through its whole range of power. Within this range any desired combination of conditions, such as speed, cut-off, etc., can be selected and maintained constant during a run of an hour or more, and while running under such constant conditions, measurements can be made with laboratory accuracy and completeness. It is this combination of constancy of conditions and accuracy of measurements which gives the tests made on a testing plant their great advantage over road tests of locomotives. Road tests with a dynamometer car are valuable for checking and completing information obtained on the plant as to draw bar pull, but in all questions of steam production and consumption, the plant results are far more authoritative. There is much detailed information which now controls locomotive design which it would have been practically impossible to obtain without a locomotive test plant.



Locomotive-boiler efficiencies in relation to rate of firing

The locomotive testing plant is of purely American origin, and though the results of the tests made here have been much studied abroad, no real testing plant has been installed outside of the United States. The first locomotive testing plant was designed and erected at Purdue University under the supervision of Dr. W. F. M. Goss, in 1891. Locomotive testing plants have, therefore, been in use for over 33 years, that is for one-third of the century during which steam locomotives have been used in America. The growth in locomotives since the first plant was installed may be measured by the fact that the first locomotive tested at Purdue was a 4-4-0 type, a representative passenger locomotive of that date, weighing in working order about 85,000 lb., while the most recent Pacific type passenger locomotive tested on the Altoona plant had a weight of 309,000 lb., or more than three and one-half times as much.

Altogether six locomotive testing plants have been built and operated. One at Purdue built in 1891, two built by the late Robert C. Quayle of the Chicago and North Western in 1894 and 1895, and one at Columbia University in 1899. These four were all of small capacity, and with the exception of Purdue have been abandoned.

The first modern locomotive testing plant capable of handling locomotives of various designs was that of the Pennsylvania Railroad built in 1904. This was designed by the late Axel Vogt, then mechanical engineer, assisted by W. F. Kiesel, Jr., the present mechanical engineer of the Pennsylvania System. This plant was first installed at St. Louis, Mo., for the Louisiana Purchase Exposition in 1904, and after operating there throughout the exposition it was transferred to its present location at Altoona.

The latest plant is that at Illinois University built in 1914 under Dr. W. F. M. Goss when dean of the College of Engineering, and Prof. E. W. Schmidt in charge of the Department of Railway Engineering. This plant follows the general design of the plant at Altoona, but provides elaborate arrangements for catching the sparks and cinders thrown out of the stack.

The bulk of the work from the various plants comes from the Purdue and the Altoona plants. The Chicago & North Western plant was of considerable service to the early American Railway Master Mechanics Association committees on exhaust nozzles. The Illinois University plant has published two reports on tests, one describing

*Abstract of paper presented at the regional meeting of the American Society of Mechanical Engineers, Altoona, Pa., October 5 to 7, 1925.

complete tests of a consolidation locomotive, the other covering tests with six sizes of Illinois coal.

The majority of the work at Purdue has been done with the two 4-4-0 locomotives built for the plant. Of these, the earlier weighed 85,000 lb. and was replaced in 1897 by a locomotive weighing 109,000 lb. which was later superheated. With this locomotive the general characteristics of locomotive operation have been studied. The most elaborate and the latest work is given in two reports published by the Carnegie Foundation in 1907 and 1910. These cover two series of tests by Dr. Goss, studying the effect on boiler and engine operation, of variations in steam pressure and variations in superheat. The information given by these and by earlier tests is of general value to a designer endeavoring to secure a proper balance between cylinder power and boiler capacity.

The installation of the Pennsylvania Railroad locomotive test plant at the St. Louis Exposition in 1904 opened a new and important era in locomotive testing. Earlier plants had been adopted only for testing light four coupled locomotives. The Pennsylvania plant was capable of handling locomotives of much greater weight and more varied design. Immediate use was made of the greater plant capacity. The series of tests made at St. Louis covered eight locomotives of widely different designs, and the data secured and published was far more complete than any previously available. These tests were the first to furnish sufficient information to enable heat balances to be drawn up for a locomotive boiler. Such balances were computed and published by the writer in 1908, and gave for the first time exact knowledge as to the relative importance of the various losses which determine the efficiency of the locomotive boiler. Since the transfer of the plant to its present location in Altoona, much work has been done in testing new locomotive designs as produced, and in providing a constantly accumulating mass of information which has made possible continued improvements in design. The greater part of the activity of the plant in Altoona has been carried out under J. T. Wallis, now chief of motive power, Pennsylvania System. Direct charge of the test plant was in the hands of C. D. Young, engineer of tests, from November, 1911, to May, 1917, and is now in the hands of his successor, F. M. Waring.

The great influence which the work done on the Altoona plant has had on locomotive design is indicated by the following statements as to the work done and conclusions reached. These are abstracted from the Pennsylvania Railroad's test plant bulletins as shown by the reference numbers.

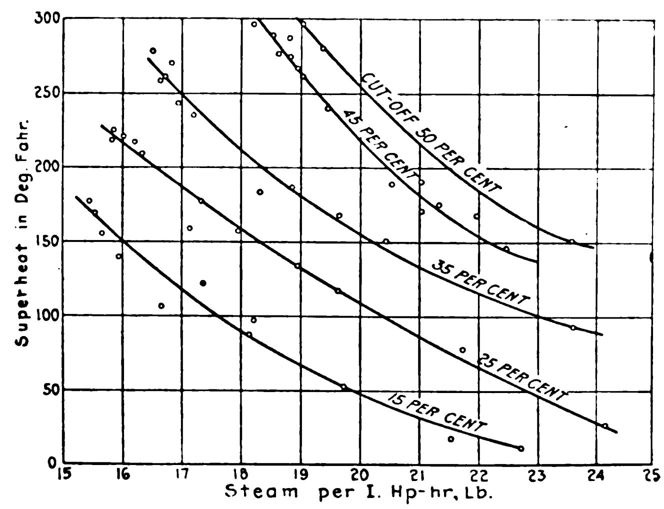
Bulletin No. 9.—A self-cleaning front end was developed which gave better results than the design recommended by the Master Mechanics Association.

Bulletin No. 21.—A comparison was made between the results obtained with long and short boiler tubes. It was established that the rate of evaporation is limited by conditions of combustion and not by a failure of heating surface to absorb heat.

Bulletin No. 23.—It was shown that a diameter of 12 in. was sufficient for piston valves for cylinders up to 27 in. in diameter, when superheated steam was used. Subsequent tests showed that valves of this diameter could be used with 30-in. cylinders with the cut-off limited to half stroke. Measurements of the stresses in the valve stems gave definite figures showing that the valve gear could be lightened to advantage by using valves of the minimum size.

Bulletin No. 24.—An extensive series of experiments on superheaters of various designs produced data showing steam consumption for varying conditions of superheat, cut-off and speed. These tests gave for the first time authentic information unobscured by other variables, as to the effect of variations in superheat on steam consumption.

Bulletin No. 27.—As a result of earlier tests on the plant, certain changes in the design of the E-6s Atlantic type locomotive were recommended. Tests of the locomotive redesigned as recommended gave a maximum evaporation 15 per cent greater, combined with a boiler efficiency nine per cent better than the original locomotive. At the same time the engine performance was generally better so that a higher drawbar pull was developed at all speeds and the maximum drawbar horsepower was increased over 20 per cent. These advantages were secured with an increase in total weight of only 2.5 per cent. Careful design of the reciprocating parts enabled them to be kept down in weight so that the dynamic augment at



Effect of superheat on steam consumption at various speeds and cut-offs

70 m.p.h. was less than 30 per cent of the static load on the drivers.

Bulletin No. 29.—Tests were made with a K-4s Pacific type locomotive built in 1914 in accordance with recommendations and experience obtained with locomotives of earlier designs on the testing plant. The coal and water rates and the high thermal efficiency showed this to be the most economical passenger locomotive so far tested on the plant. For any given amount of fuel fired, this locomotive developed more power than any previously tested at the test plant.

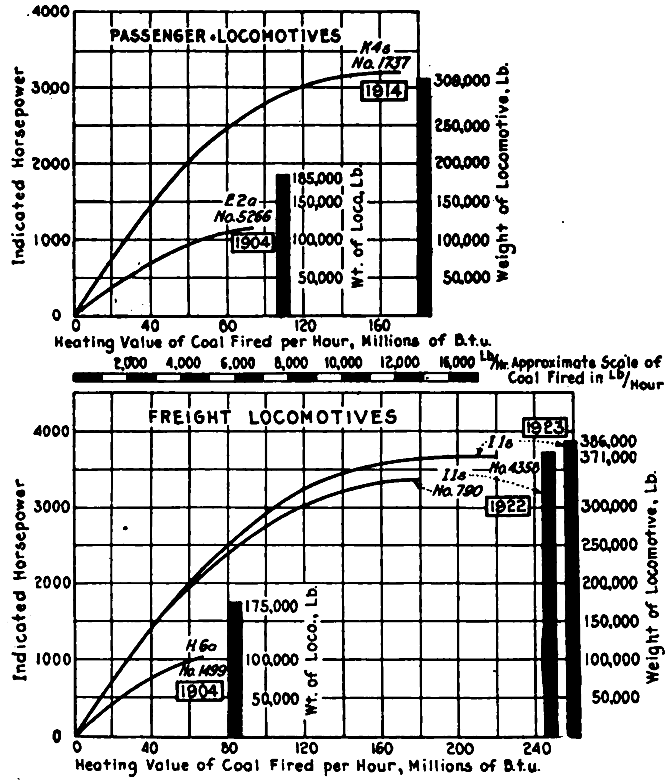
Bulletin No. 30.—Accurate tests demonstrated the advantage gained in boiler efficiency by the use of a brick arch when high volatile bituminous coal is being rapidly burned.

Bulletins No. 31 *and* 32.—The testing plant having shown definitely the great difference in steam consumption between cut-off at full stroke and cut-off at half stroke it was logical to attempt to produce a freight locomotive which, even in low speed drag service could operate at cut-offs of not over 50 per cent. The result was the development of the Ils Decapod class locomotives with a boiler pressure of 250 lb. per sq. in., instead of 205 lb. and with cylinders enlarged to enable full power to be developed without using a cut-off longer than 50 per cent of the stroke. Compared with the previous standard freight locomotive, the new locomotive with an increase of 16 per cent in weight gave an increase of 25 per cent in power, and in full gear at low speed showed a reduction of 38 per cent in steam used per indicated horsepower. This type of locomotive with feedwater heater added, giving a further increase of two per cent in indicated horsepower, is now

the standard freight locomotive of the Pennsylvania System.

One of the charts has been prepared to show the growth in the size and efficiency of the passenger locomotives of the Pennsylvania Railroad since the test plant was put into service. The E-2a Atlantic type locomotive of 1904 is compared with the K-4 Pacific type locomotive of today. The curves show the indicated horsepower in relation to the rate of firing. The heavy vertical lines represent the locomotive weights. The weight has increased from 185,000 lb. to 309,000 lb. The maximum horsepower has increased from 1,200 hp. to 3,300 hp. The increase in power has been much more rapid than the increase in weight. This can be seen from the fact that the indicated horsepower developed per 1,000 lb. of locomotive weight has increased from 6.5 hp. to 10.7 hp., that is, by 65 per cent.

So far we have described the work of the Altoona test plant by abstracts from the bulletins which deal mainly with the solution of concrete problems arising out of the testing of certain definite designs of locomotives. The test plant has, however, been of great value in providing material for a study of locomotive operation in general terms and in thus advancing our knowledge of the subject. Probably the greatest advance has been made in knowledge pertaining to the factors which determine boiler efficiency. Before the Pennsylvania test plant results had



Growth in size and efficiency of steam locomotives

been studied, speculation was active as to the best proportions to be assigned to firebox and heating surface, but our definite knowledge was scanty. Dr. Goss's work had indicated that the losses by incomplete combustion were large, but with no information as to the amount of air consumed, accurate knowledge as to the details of combustion and heat absorption was lacking. The Pennsylvania test plant has changed this. During the recent tests of the Missouri Pacific three-cylinder locomotives, the writer was shown a curve of estimated smokebox temperatures drawn up before the tests were started. These, in the majority of cases, did not differ from the results actually obtained by more than 15 deg. F.

All locomotive boilers show a drop in efficiency with an increase in the rate of operation, and if the efficiency is plotted against the rate of firing it is found that the relation is best expressed by a straight line. The straight line for the boiler efficiency of the K-4s Pacific type locomotive is shown on the chart of boiler efficiencies in relation to rates of firing. The Pennsylvania test plant results if analyzed enable us to split up this overall boiler efficiency into two components—

a—Efficiency with which heat is produced.
b—Efficiency with which heat is taken up by boiler.

These component efficiencies follow closely straight line laws, as shown on the chart.

The information thus secured is important in any attempt to improve the boiler efficiency. The line for the efficiency of heat absorption shows but slight variation with the rate of firing, the values being uniformly high, ranging from 86 per cent to 80 per cent. These figures represent the heat taken up as percentage of the heat actually produced. Now the smokebox gases cannot possibly be cooled below the temperature of the water in the boiler. Therefore, not all of the heat produced is absorbable by the boiler. It can be computed that the boilers in question are taking up between 94 per cent and 88 per cent of the heat which it is physically capable of absorbing. This is characteristic of modern locomotive boilers, and it is evident that as pieces of heat interchange apparatus they are highly efficient and that there is but a small margin for improvement in heat absorption.

The efficiency of combustion shows a different condition. Here an efficiency of 100 per cent is possible and is shown by the tests to be reached at low rates of combustion. At the ordinary rates of operation, however, usual values are in the neighborhood of 60 per cent or less.

There is evidently a considerable field for improvement here, but it must not be assumed that improvement is easy. There is necessity for considerable study before the final answer is given. The diagrams show that boiler efficiency can be improved by reducing the rate of firing per sq. ft. of grate area. If the same power is to be maintained this means an increase in the size of the grate so that the total amount of coal burned may be maintained. Locomotive designs adopted by various railroads in the last few months show development along this line, but as yet no locomotive testing plant analysis of performance is available.

In this connection, the writer calls attention to the fact that in the discussion of boiler efficiency in relation to the rate of operation it is usual, as has been done above, to measure the rate of firing in terms of coal per sq. ft. of grate area per hour. This assumes that the grate area is the controlling factor in determining the efficiency of combustion. Grate area is an important factor, but not the only one. Firebox volume must also be given consideration.

The test plant data is not yet sufficiently complete to permit a determination of the relative values of grate area and firebox volume, but one series of tests with high volatile coal suggests that with this fuel the volume is the more important. The point deserves more study and it may be found that combustion efficiency can be best improved by a slight increase in grate and a considerable increase in firebox volume with appropriate arrangements for giving a long flame-way.

The question is extremely complex and can be most adequately answered by further test plant work. Doubtless this is but one of many problems by the solution of which the locomotive test plant will advance still further the development of the steam locomotive.

For the future we look with confidence to a continued

growth in the use of the locomotive testing plant. The great increase in locomotive efficiency which has taken place in the last 20 years makes further advance more difficult, and makes exact knowledge a necessary condition for such advance. As it is the function of the locomotive test plant to provide exact knowledge it is not surprising that new plants are under consideration by railroads and by locomotive builders. A great step forward could be made if the American Railway Association were to construct or to take over a locomotive test plant to be devoted to the scientific and impartial study of locomotive designs and devices and to research work concerned with the basic scientific laws governing locomotive operation. Correct locomotive design is only possible when the definite natural laws governing locomotive operation are known.

The foreman and his responsibility

Two more of the contributions which were submitted in the competition on this subject

So much attention has been given by our readers to the articles by contributors to the *Railway Mechanical Engineer* competition on the foreman and his responsibilities and opportunities that the following contributions have been selected for publication:

A roundhouse foreman's viewpoint

By Charles Frederick Maw

Locomotive foreman, Canadian National, Grand Trunk Lines in England, Island Pond, Vt.

A prominent railroad official was recently heard to say "The roundhouse foreman is one of our main keys to success." Let us see for a moment how this works out. Railroads are carriers and must have motive power. To efficiently handle and prepare the power of the various American and Canadian railroads an army hundreds of thousands strong has to be maintained. Every roundhouse, machine shop, or main shop is a busy hive of industry with its necessary quota of charge hands, gang foremen, etc., under the supervision of the locomotive or general foreman, as the case may be.

The importance of the foreman's position is obvious. He is the one man oftentimes standing between the officers or management and the employees. On his shoulders fall the responsibility of rightly or wrongly interpreting the policies laid down. To be a foreman in every sense of the word requires certain essential qualifications without which, if the foreman holds down his job, he is merely *just getting by*.

A foreman's qualifications

1. He must be a man as well as a foreman. If he has worked up from the ranks, he is cognizant of the many little troubles which daily confront the mechanic and by a judicious word here and there, can immeasurably improve the efficiency of the staff. Firmness is necessary and rightly so, but it should be tempered with good judgment and common sense. Creating "sore heads" gets nowhere.

2. He must have a good general knowledge of all duties under his supervision. I remember some years ago, a man was promoted to roundhouse foreman because of his exceptional ability at valve setting. He proved a failure. Why? Because, while he had made a determined and praiseworthy effort to master the subject of valve setting, he had studied practically nothing else and knew little or nothing about the handling and supervising of men. The foreman must be more versatile than any other man on the railroad system. Besides being of at least average mechanical ability, he must be alert to grasp the detail of the thousand-and-one things of other than mechanical nature which come under his jurisdiction.

3. He must be an organizer. This is especially the case with the roundhouse foreman. Just as raw troops, well led, have accomplished at times almost the impossible, so the roundhouse force measures up its foreman and matters progress or retrogress accordingly. His, the eye to note, as he daily goes his rounds, the weak links in the chain. His, the mind to plan and then he, the person to enthuse his charge men, gang foremen, shop foreman, boiler foreman, etc. He should encourage good work but should also make adjustments, as the service demands, without fear or favor. He should cover the whole territory under his jurisdiction at least once every day.

4. He must be approachable and diplomatic. A great deal depends on the manner in which the foreman receives a deputation of organized labor. He must uphold the policies of his employers and at the same time be courteous with the representatives of the men. If at the time it is impossible to grant their request, he must so advise them in a diplomatic manner. Likewise, when a change of policy is brought about by his employers, he must endeavor to bring this about in the roundhouse, shops and works without antagonism or estrangement. To use an expression of an old friend of mine: "A few drops of oil are oftentimes worth many tons of sand," in cases of this nature.

The personal touch so lacking in these days of organized efficiency is a great asset to the foreman fortunate enough to possess it. In small communities, the foreman is often looked to by the men as a standard by which to set their moral gages. Fortunate indeed is he who can leave a small city or town after a few years' service as locomotive foreman with the general good will of the community and the record, *"he was a square boss."*

5. The foreman must be resourceful. Oftentimes tried in the past and daily tried again is surely the foreman's lot. He frequently lacks material and must substitute (which he seldom fails to do) something equally as good. The power must be maintained and the business moved or the road suffers. The passenger power must do the job and run to schedule or the public is heard from and it begins to use the passenger trains on another road. Passenger returns drop off. The traffic department hunts in vain for business. Dividends come not. All because the little known and generally misunderstood locomotive foreman is not doing the job. Change the scene, however, and with a live wire foreman everything is prosperity, so far as efficiency of power is possible to make it so.

Lastly, the foreman should be looking ahead. Do the

railroads give their foreman the encouragement he oftentimes deserves? Do they realize the time he puts in studying and working to improve himself that their service may be more expeditiously and efficiently handled? Surely this is one thing to which the foreman is entitled. He has to be an administrator of no mean ability to ensure success and employers should give him every encouragement and also every possible opportunity for advancement.

Must study the men

By William J. Eagan
Lehigh Valley, Sayre, Pa.

Relationship of the foreman to his men is a study which requires more than superficial examination. He is the compound which cements the man to the company in spirit as well as in practice.

He should show that he has confidence in the ability of the men under his charge to do the work assigned to them without constant watching and suggestions from him—nothing makes a force more disgruntled than the knowledge that it is being constantly watched or thought incompetent.

If a man is not properly placed he should be transferred and placed on a job that he can handle efficiently; a supervisor flagrantly displays his own incompetency by holding a man on work which he is not capable of performing efficiently.

How often do we go through a shop and see the foreman performing duties that can easily be taken care of by laborers? When the men see this going on continually, they lose confidence in the ability of the men higher up to choose leaders in the shop, and most of them have aspirations terminating, at least temporarily, in a foremanship.

A foreman should be firm without being arrogant, especially when approached by a man with a grievance. Listen to him, and if you can't adjust it at once, give him every assurance that it will receive consideration. Likewise, if he has a suggestion for an improvement in a method to increase production or for safety first, or that will better the appearance of your department, encourage the suggestion, recognizing the fact that a foreman is only as strong as is the force under him. See also that a man receives recognition from the office for such diligence. Too often the foreman has overlooked such suggestions or acted upon them as his own.

Give your time to the company unstintingly, even though there is no direct compensation from the additional effort; a foreman or man who is looking from one pay day to the next has about reached his limit, and a foreman who has that attitude will quickly relay it to his men. The company isn't a place to get a living from so much as an organization that gives a living and an opportunity to succeed.

Don't play favorites, because when they are placed upon their own feet they usually topple, and a system loaded with favorites shunts all the work upon one or two men—such an organization will fail of its own weakness. Remember, always, that an organization is only as strong as its president, and he is as strong as the assistants he picks to help him, and so on down through the whole production family to the most unskilled man. Any weak link reflects upon the man choosing or holding him.

Rock Island remodels Vanderbilt type tenders

Tank of new design applied to standard underframe—Capacity increased to 10,000 gal.—Maintenance cost reduced

The Chicago, Rock Island & Pacific has embarked on a program of improving and rebuilding 107 Vanderbilt type tenders used in conjunction with 30 Pacific, 75 Mikado and 2 Mountain type locomotives in service on that road. The cost of conversion will be about \$3,500 a tender and it is estimated that the new design will pay for itself in reduced maintenance cost within a period of slightly over four years. The original Vanderbilt tenders, purchased in 1912 and 1913, were always subject to excessive maintenance cost, owing to the fact that buffing stresses were transmitted through comparatively light plates and angles to the tanks and when the holding rivets worked or sheared off, leakage resulted and the tenders had to be taken out of service. This condition gradually became worse as the tenders got older and plates forming the lower half of the tank circle corroded and deteriorated.

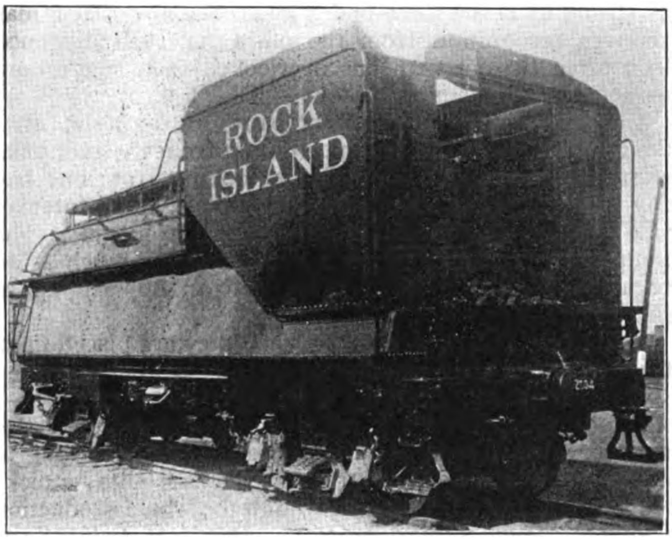
A careful individual check was kept of the expense of repairing eight Vanderbilt type tenders on the Rock Island, the figures showing an average cost of \$864 every 12 to 18 months, or in fact each time the locomotive came to the shop for heavy repairs. This excessive cost, in conjunction with service delays owing to the development of leaky tanks on the road, eventually became so serious that it was evident some determined effort must be made to meet the situation. The weaknesses of the old tender design were studied and, under the direction of W. J. Tollerton, general superintendent of motive power, and George Goodwin, mechanical engineer, a new design developed which gives promise of solving the problem.

By the new design the tank of the Vanderbilt tender is completely remodeled, the lower half containing the deteriorated plates being cut away with the oxy-acetylene torch, and a new bottom substituted which is expanded to the full width of the tender at the bottom and is anchored in the customary manner to the conventional design of four-sill tender frame. The new construction is indicated in the drawing and photographs.

While some additional capacity is gained by widening the tank at the bottom a certain amount is lost through cutting off that part of the original tank cylinder which extended below the top of the present tender frame. The tank length in the new Rock Island design has been in-

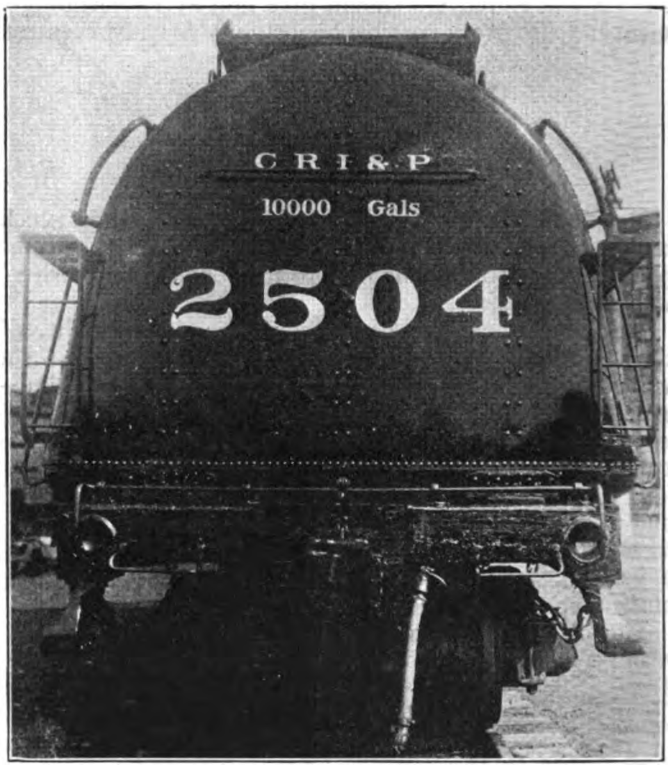
creased 30 in. which gives a net added capacity of 1,000 gal., or a total capacity of 10,000 gal. It is obvious that a still further increase in capacity could be obtained by adding a suitable amount to the length of the tank and providing trucks to take care of the increased load. The coal space has not been changed. In case the tender is to be used with a stoker-fired engine, however, a trough for the conveyor screw can be readily provided in the design of the new tank bottom.

Referring to the drawing, the changes made in the old



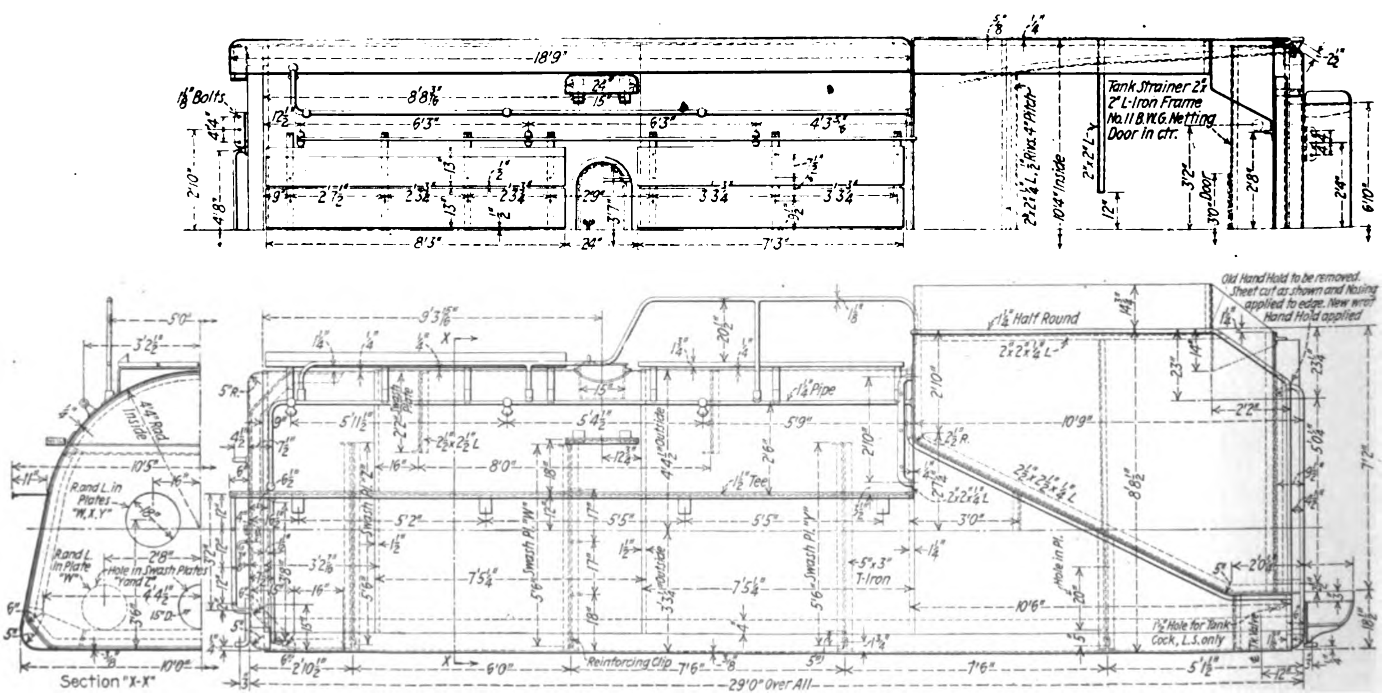
Vanderbilt tender remodeled and rebuilt in accordance with Rock Island design

Vanderbilt tank will be evident. The upper cylindrical course has been bent out on each side and new courses added, to be joined to the new bottom plates by riveted joints. The bottom of the new tank, which contains practically no rivets, would be made of a single plate if one of the desired size could be obtained but, lacking that, two plates are used, joined by a reinforced, electric, butt-welded joint along the center line of the tank. It will be observed that the bottom plate does not come to a sharp corner and join the side plate by being riveted to one flange of an angle iron as is customary with rectangular tanks. Instead, the edges of the bottom plate are bent to a 5-in. radius and riveted directly to the side plates. This eliminates one joint, leaving but a single joint which



The tank, expanded at the bottom to the full width of the tender, is supported on a standard tender frame

is in such a position as to be easily caulked, and giving a more flexible construction. This particular feature of the remodeled Vanderbilt tanks has been thoroughly tested on the Rock Island and shown to be a big improvement over the angle iron corner construction which not



New tender design developed by the Rock Island to overcome weakness inherent in its Vanderbilt tenders

only has the additional joint but offers so rigid a resistance to the weaving action of the tank under the surge of the water that something must give and as a result the plates or angle irons crack or rivets work loose.

Another feature which tends to prevent leaky corners with the new design is the provision of special, continuous, U-shaped braces to stiffen the lower half of the tank and make it retain its shape under stress. There are three of these braces, made of 5-in. by 3-in. T-iron, and by forming the sides and bottom of each brace of one continuous piece it is possible to get away from the weak construction of having side braces which terminate at the bottom corner of the tank and cause leaky rivets at that point under the weaving action of the tank. As shown in the drawing, the braces are not fitted exactly to the corners of the tank but the change in direction from the sides to the bottom is accomplished by two bands of 6-in. radius each and a short section of 45 deg. slope. The back head of the tank is new and the splash plates are fitted with new T-irons. The running boards are raised and hand rails and ladders changed to suit. The cost of remodeling the tank including the provision for an increase in capacity of 1,000 gal. is $1,600.

One of these tenders, after being out of the shop nearly two years, came in for general repairs, the entire cost of tender work being $40, most of which was caused by the application of a new pair of wheels. In other words, the maintenance on the tank itself for the first two years was negilgible. Even as the remodeled tenders get older, the cost of maintenance will unquestionably be but a small fraction of that of the old Vanderbilt type tenders. The entire conversion program wiil cost approximately $3,500 a tender, including labor, material and shop prorata, and this cost will be practically wiped out in a period of a little over four years.

Ten of the Vanderbilt tenders have been converted to date and the success of the new design has been such that it is being considered for application to new power.

A study of locomotive whistles

The whistle should be located in front and placed in a modified parabolic reflector

By Arthur L. Foley

Head of department of physics, Indiana University, Bloomington, Ind.

ABOUT five years ago the writer was employed by a railroad company to test the whistle, bell and headlight of one of the company's locomotives that had killed and injured a score of school children in a hack at a road crossing. The driver had obeyed the warning to "stop, look and listen." Apparently he had not seen or heard, although he had gotten out of the hack and walked to the center of the railroad track trying to do so. Why? I shall not try to answer this question in this specific case. It is the general case that most concerns us, for such accidents are quite common.

No doubt the crossing menace would be lessened somewhat, but it would not be removed, if by legislation or otherwise the public could be induced to stop, look and listen. Most crossing accidents involve motor cars. If the driver stops and sits in his car, his seeing may be prevented by buildings, corn fields, or other obstructions, and his hearing by motor noise, particularly in the case of the closed car. If the driver gets out of his car and walks to the center of the track and looks, he may even then, due to track curvature or adverse weather conditions, not be able to see an approaching locomotive as far away as would be necessary for safety. He may see the locomotive at a considerable distance and be deceived in thinking that he has plenty of time to cross the track before the train can reach the crossing. It should be remembered that a train running 60 miles per hour travels a third of a mile in 20 sec., the average time required for a driver to return to his car, take his seat and drive the car to the track. These facts, together with the obvious fact that nothing short of an army of police could bring about a general observance of the "STOP" part of the warning, emphasizes the importance of the "LISTEN" part of it. It is more important than the "LOOK," for the driver of a car who does not keep his eyes rather closely focused on the road he is driving over is more dangerous to traffic than is the locomotive whose path is fixed. But the driver may listen all the while, and may hear a locomotive which it would be impossible for him to see. It is timely, therefore, to consider the efficiency of locomotive whistles as danger signals, particularly since closed cars are coming into such general use. Such cars shut out a considerable fraction of the whistle sound and shut in much of that from the motor. The sound from the whistle must be sufficiently intense to be heard above, and of such a character as to be differentiated from, the hum of the car's motor and other mechanism. The locomotive whistle in common use signally fails to meet these requirements. It is rather strange that it has survived so long in this age of striving after efficiency.

Actual distribution of sound about a locomotive whistle—Ear estimates

The writer's first experiments on this question consisted in determining how far a certain locomotive whistle could be heard in various directions from the locomotive, when the listeners were in a closed automobile standing still with engine running, and again with engine stopped. Also when in a touring car under the same conditions. Ear estimates of the whistle intensity were made by each of five listeners when the automobile was stationed 1,200 ft. from the locomotive, in various directions, with the engine running and when the engine was stopped, on clear days and foggy days, and on days with various wind velocities. Finally, ear estimates were made of the relative intensities of the sound of the whistle at various distances ranging from 1,200 ft. to four miles, when the listeners were standing on the ground near an automobile with the engine running, and 20 ft. from the car with the engine running and when stopped.

The results of these and similar observations will not be given here, as they were confirmed by later quantitative experiments which will be discussed in some detail.

However, the writer has no apology to offer for mentioning such apparently crude observations. After all, it is the ear effect that the locomotive engineman must depend upon to save the lives of those crossing the railroad tracks, and the railroad company from damage suits. If the results of the ear estimates differed essentially from those made mechanically, I should discard the latter and base my conclusions on the former.

Quantitative measurement

In Fig. 1 is shown the respective radii of the 10 points (crosses) on the broken curve *A*, which indicate the relative sound intensities in the ten indicated directions from a chime whistle *W* on a locomotive *L* standing on a turntable on the track *T-T*. The intensities were measured with a Rayleigh disc. On the first day the observations were attempted a Webster phonometer was used to measure the sound intensity. On account of the extreme sensitiveness of this instrument to small changes of pitch, it was not satisfactory for the work in hand. It was, therefore, with little regret that the writer was forced to discontinue his experiments that day on the demand of some one to whom the noise of the whistle was objectionable.

Before undertaking the experiment a second time, the writer experimented on different forms of Rayleigh discs. The instrument in the form finally chosen was less sensitive than a tuned Webster phonometer, but had a much wider range through which the pitch of the sound might change without seriously affecting the instrument's sensitivity.

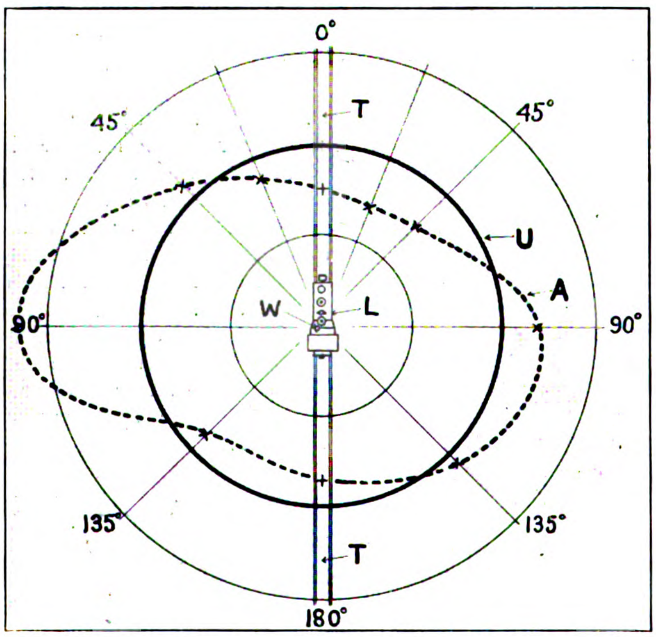


Fig. 1—Sound intensity, curve A, about a locomotive whistle mounted near the steam dome

The intensities shown in Fig. 1 were measured in the 10 directions shown, at a uniform distance of 1200 ft. from the whistle. Instead of moving the observing station the locomotive was placed on a turntable and the observing station located permanently at the side of the track 1200 ft. from the turntable. Then the locomotive was successively turned so that the relative direction of each of the 10 observing stations was that indicated by the respective numbered radii in Fig. 1.

Even had it been possible to move the Rayleigh disc and adjust it to the same sensitivity in all 10 positions, and had the time required been no consideration, the scheme of turning the locomotive had many advantages. It minimized, by making more nearly constant, the disturbing effects of winds, temperature changes and differences, the varying topography of the surrounding landscape, and reflections from houses, trees, and other objects.

The continuous curve *U* shows what the sound intensities in the several directions would have been if the sound of the whistle had been radiated uniformly in all directions. Note that the sound of the whistle, curve *A*, was actually more intense behind the locomotive than in front of it, and two or three times as intense at right angles to the track as along the track. In other words, most of the sound energy was dissipated at right angles to the track. Why this objectionable distribution?

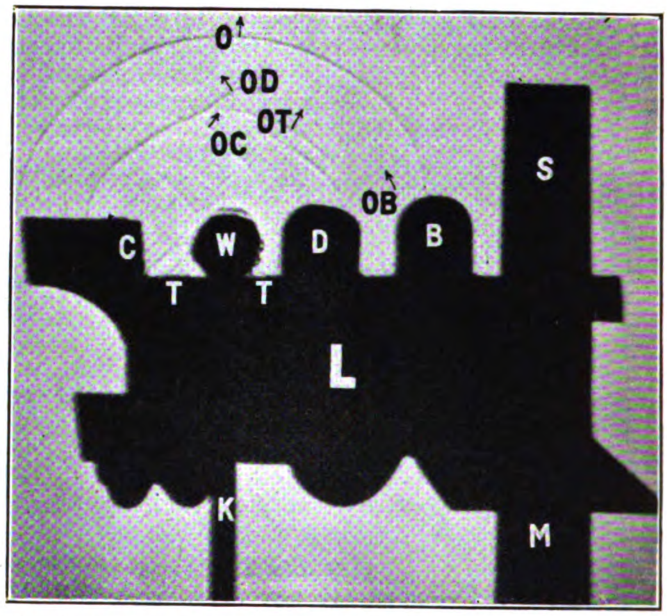

Fig. 2—Sound waves from an electric spark reflected from parts of a miniature locomotive

The general contour of curve *A* is about what one should expect from a whistle located as this one was, to the side of and rear of and only a few inches from, a steam dome several times as large as the whistle itself. Sound reflection from the steam dome and other parts of the locomotive and sound absorption by the hot gases issuing from the smoke stack and rising from the boiler explain the matter. Let us consider these effects separately.

Sound reflection

From the standpoint of sound reflection, also refraction and absorption, as we shall see later, the location of a locomotive whistle is bad, usually about as bad as if it were placed inside the cab or under the locomotive itself. It is always behind the stack, usually behind one or more domes and the bell, and frequently immediately behind or at the side of pop valves or other accessories mounted on the top of the boiler. All of us know that if we wish to shout to some one at a considerable distance that we turn toward the listener so that the sound will be projected initially in that direction. All of us know that we can be heard at a greater distance if we do not stand behind a lamp post or a tree when we shout. Nevertheless, we continue to locate whistles from the standpoint of convenience only, with no thought of a possible connection between the whistle's location and its efficiency in doing the only thing it is expected to do; namely, to make as much noise as possible in front of the locomotive

and as little as possible where it is not only not needed, but is usually a nuisance.

When the whistle is placed behind the smoke stack, dome, etc., all these objects reflect the energy of the portion of the sound wave that falls upon them. Since a sound wave has been long compared with a light wave, the sound shadows thus produced are not comparable in density or definiteness to the light shadows that would result were the whistle replaced by the headlight. Nevertheless, there are sound shadows of more or less intensity, depending on the size of the object casting them and on its distance from the sound source. In other words, depending on the solid angle of the object as seen from the sound source. Where the distance is small and the angle large, as when a whistle is mounted very near a dome or a pop valve, immediately behind or at one side in some recent practice, the intensity of the sound ahead of the locomotive is decreased and at the side or rear increased over what it would be were the whistle mounted in front of the smoke stack. This is clearly shown in curve *A* of Fig. 1, and is illustrated in Figs. 2 and 3.

If the reader's imagination is sufficiently strong, perhaps he may think of *L* in Figs. 2 and 3 as a crude miniature locomotive with exaggerated dimensions of some of the parts. The smoke stack *S* was the upper end of a metal tube *M* about two feet long, which served also to support the model. *C* is the cab, *D* the steam dome, *B* the sand box and *T-T* the top of the boiler. The whistle *W* consisted of a spark gap behind a disc of insulating fibre, the gap being about ¾ in. long and connected through conductors *K* to an electric influence machine. The crack of the electric spark produced the sound waves shown in the figures. These waves were photographed by a method described by the author in the November, 1912 Physical Review and also in the Scientific American supplement of February 15, 1913.

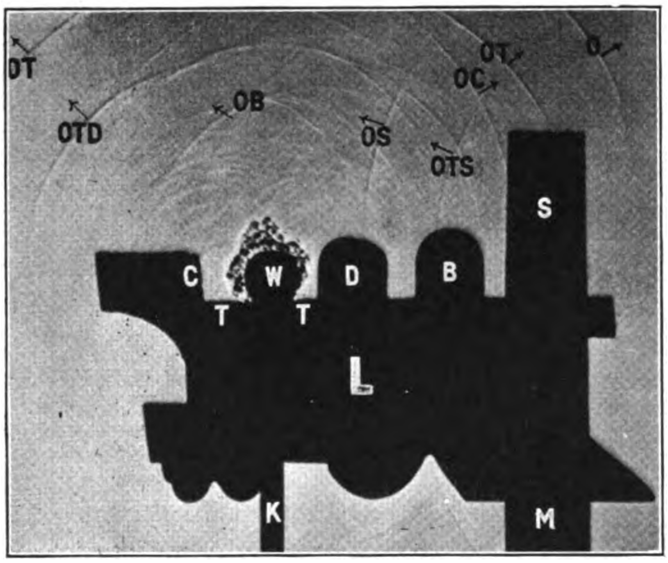

Fig. 3—Sound waves from an electric spark, showing sound waves of greater radius than those shown in the preceding figure

In Fig. 2, *O* is the original sound wave produced by the spark at *W*. If the wave had encountered no obstructions it would have traveled outward from *W* uniformly in all directions, as in Fig. 4. We note, however, that there have been many reflections. *O B* is the reflection of *O* from *B* "caught in the very act." *O T* is the reflection of *O* from the top of the boiler *T*, *O D* from the steam dome *D* and *O C* from the cab *C*.

It is interesting to trace the further development of these waves, as shown in Fig. 3, a photograph taken about .0001 sec. later than the photograph in Fig. 2. The same lettering is used in both figures, the arrows indicating the direction of the waves. In Fig. 3 the original wave has passed out of the field on the left of the picture and shows only at *O* at the upper right hand of the photograph. *O S* is a reflection of *O* from the stack *S*. Note that *O T* in Fig. 2 has expanded, struck the stack *S*, and given us the wave *O T S* in Fig. 3. *O C* of Fig. 2 has just arrived at the stack in Fig. 3.

It is not necessary to trace all the waves that have been formed. It is sufficient that we see that, owing to numerous reflections, the space above the model locomotive is filled with waves, that most of the sound energy is headed upward, and that there is not enough in front of the locomotive to show in the picture.

Owing to the shortness of the spark waves and the exaggerated dimensions of some of the parts of the miniature locomotive, Figs. 2 and 3 exaggerate the magnitude of the effects of reflection. They do, however, quite accurately represent their nature.

Sound refraction and absorption

The very undesirable sound distribution shown in curve *A* of Fig. 1 would be much worse in the case of a locomotive running at high speed. A locomotive standing on a turntable requires very little firing to keep up the steam required to operate the whistle. There is little smoke from the stack, and what there is rises some distance before deviating much from a cylindrical form. It is very different when a locomotive is moving rapidly. When running the exhaust steam is blown through the stack to increase the draft, causing smoke and hot gases to be ejected in large volumes. These, together with the convection currents from the hot boiler, are swept back over the locomotive, forming a sort of gas, steam and smoke blanket through which the sound of the whistle must pass.

It is a well-known fact that a part of the energy of a sound wave is reflected when it falls upon a stream of hot gases; some is absorbed in the stream itself and that which gets through is dispersed. The loss due to absorption and dispersion is much greater than one might imagine. If anyone doubts this statement let him stand on one side of a bonfire and try to talk to some one on the other side. He may fail to make himself heard at all.

A striking illustration of the blanketing effect of air currents and air strata of different temperatures is observed in the variation of the intensity of the sound of the exhaust of an aeroplane engine as it passes over. Sometimes the roar of the engine is quite loud, sometimes it is weak, perhaps inaudible. The shifting air currents and the changing path that the sound must take to reach the ear from a moving plane cause the intensity variations.

The intensity of sound in the shadow of a stream of hot gases is generally much less than it would be were the gas stream replaced by a solid obstacle of the same size. This point is illustrated in Fig. 4, which is a photograph of sound waves passing through or around cylinders of hot gases and metals. *W S* is a sound wave produced by an electric spark, perpendicular to the plane of the figure, behind the disc *S*, and *W G* a wave produced by a like spark behind the disc *G*. The sparks were made to occur simultaneously by connecting the two spark gaps in series. The waves *W S* and *W G* are consequently of the same size and intensity. *C* is a metal cylinder one inch long, of the same length as each of the spark gaps. When a spark passes at the gaps *S* and *G* there is a sudden heating of the air between the terminals of the gaps, producing at each one an expanding mass of hot air of

approximately cylindrical cross section. By properly adjusting the distances between *S*, *G* and *C* and by carefully timing the illuminating spark by which the photograph was taken, the waves were photographed in the positions shown in the figure.

Inspection of Fig. 4 shows that in passing the solid cylinder *C*, the portion of the wave *W G* which struck the cylinder was reflected to *W C*. The portion passing just above and just below the cylinder was being diffracted into the region *R* in the general direction shown by the arrows *D*, *D*. The solid cylinder did not, therefore, cast a definite sound shadow, though the sound intensity in *R*, the sound shadow region, was less than it would have been if *C* had not reflected some of the sound energy.

Note the difference in the region *A*, which is the sound shadow region behind the hot gases produced by the electric spark at *S*. Apparently all of the sound energy that entered the hot air cylinder near its central and therefore thicker and hotter parts was absorbed. Only those parts of the wave entering the upper and lower edges of the cylinder where the gas was not so hot and the distance to be traversed not so great was transmitted. Owing to the fact that the velocity of sound increases with the temperature these transmitted portions of the wave were refracted in the direction of the arrows *T*, *T*, the edges of the hot air cylinder thus functioning like a dispersing lens. Consequently the intensity of sound in region *A* was less than in region *R*, the hot air cylinder casting a deeper sound shadow than a solid body of the same size. It appears, therefore, that the disturbing effect of the high smoke stack of Figs. 2 and 3 would have

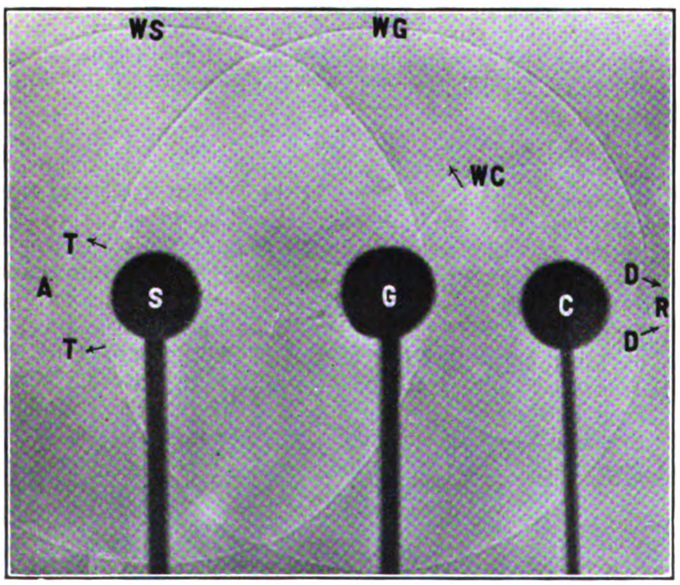

Fig. 4—Sound waves due to simultaneous electric sparks at G and S, showing diffraction about a solid cylinder C, and dispersion of the hot gas cylinder at S

been even greater had the stack been low, with hot gases issuing from it. And had the gases been blown back over the locomotive, the effect would have been even more disturbing.

A suggestion of the magnitude of the effect may be gained by comparing Fig. 3 with Fig. 5. In the latter a small bunsen burner was so placed that the tip of the flame was in the lower end of a brass tube, the upper end of which formed the smoke stack *S* of the miniature locomotive *L*. The hot gases issuing from the stack were blown back over the locomotive by means of an air jet in the direction of the arrow *A*. Observe that the original sound wave *O* is about the only one that shows in Fig. 5 and this only over the rear half of the locomotive. There is no trace of a wave near the stack, where the gases are hottest. The wave has not been hidden by smoke. What one sees in the picture is not the photograph of smoke at all. The air inlet on the gas burner had been adjusted so that the gas burned with a smokeless flame. One does not see smoke when he sees the heat, really the convection currents, rising from the hot radiator of his automobile. However, hot gases may be quite transparent to light and not transmit sound.

If the disturbing effect of hot gases and heat currents

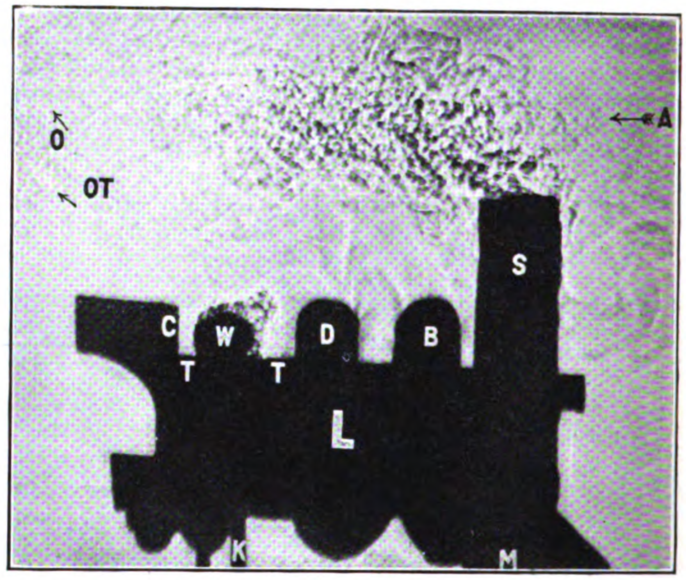

Fig. 5—Absorption of sound energy by the hot gases from the smoke stack of a miniature locomotive

were the only reason for locating a locomotive whistle ahead of the smoke stack it would be a sufficient one. It is noted that the sound was weaker both in front of and to the rear of the locomotive than it would have been had the sound distribution been uniform, while at right angles to the track, particularly on the left side of the locomotive, the intensity was much greater than with uniform distribution.

Another factor which had to do with the sound distribution shown in Fig. 6, is the design of the whistle itself. The usual cylindrical tube forming the resonator (bell) of a single tone whistle is, in the case of the chime whistle used in this study, divided by longitudinal radial vanes into five compartments or pipes, each of the proper length to give one of the notes of the chime; namely, *C*, *E*, *G*, *C′* and *C″*. *T* in Fig. 6 is a transverse section of the whistle and *L* a longitudinal section, with the omission of the valve mechanism at *V*. The former shows the relative positions and cross sectional areas of the five pipes while the longitudinal section shows the relative lengths of two of the pipes *C* and its octave *C′*. The fraction of the cylindrical steam jet *J* used in blowing each of the pipes is shown in the transverse section *T*, and was 26 per cent in the case of the lower tone *C* and respectively 22, 19, 17, and 16 per cent for the other four tones. Thus 60 per cent more energy was used in blowing the lower tone than in blowing the upper tone of this whistle.

Since the quality or character of a sound depends on the relative intensity of the several tones which combine to form it, it is evident that the quality of the sound from a chime whistle depends to a degree upon which pipe of the whistle is toward the observer. This variation with direction is accentuated when the whistle is

placed near a steam dome, which interferes more or less with the normal functioning of that part of the whistle which happens to be nearest it. Inasmuch as the Rayleigh disc was not equally sensitive to all five tones of the chime, intensity measurements made with the disc showed considerable variation whenever there was a change in the orientation of the whistle with respect to the dome.

The writer would locate a locomotive whistle in front of the locomotive where it would be free from the several disturbing factors named. He would place it in a reflector of such design as to give a maximum of sound intensity ahead of the locomotive and of such size as to serve as a resonator and thus increase the intensity of the sound at the source.

In advocating the use of a reflector to direct the sound of the whistle along the track the writer has continually met with the argument that such a device would be practically useless on account of the fact that the reflector could not be made large compared to the length of the sound waves to be reflected. This limitation does, of course, affect profoundly the rate at which sound wave energy spreads out after the waves are outside the reflector. But it does not change the action of the reflector itself. The energy of the reflected portion of the sound wave can be headed in the right direction, and much of it will continue in the right direction to reinforce the wave originally projected in that direction. In proof of this assertion it is sufficient to call attention to the effectiveness of a megaphone as a sound director. We should expect a relatively greater directive action from a reflector placed about a whistle. In the case of the voice the waves are originally projected in one hemisphere only, the whistle starts them in both hemispheres. The whistle reflector reflects a portion of the waves in the one hemisphere, as does the megaphone; but in addition it turns back those that start in the other hemisphere.

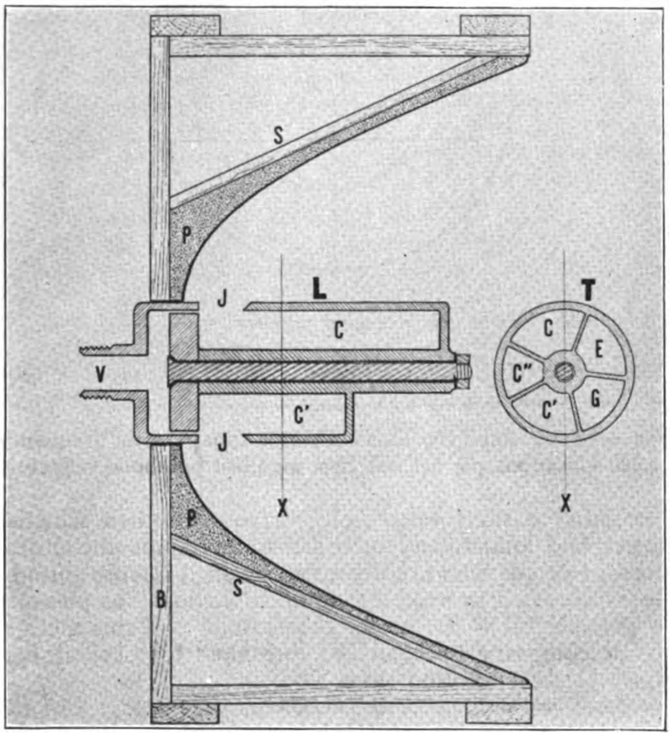

Fig. 6—Transverse and longitudinal sections of a chime whistle modified parabolic reflector

It is strange that the belief that sound can not be reflected by anything except a very large body is so persistent and so general. A person who voices this belief is quite inconsistent when he places his hand to his ear in order to hear a speaker not easily understood with the unaided ear. Even a mule knows that sound can be reflected. He turns his ears in the direction from which the sound comes. It must be admitted that the ears are not as small as they might be, but they are not as long as the sound waves the mule must interpret.

To determine whether or not a reflector of moderate size could be made to exert any considerable directive force on the sound from a locomotive whistle, the chime whistle previously described in this paper was placed in a parabolic reflector, as shown in cross section in Fig. 6 in which all dimensions are to the same scale. The whistle was 6.5 in. in diameter and the aperture of the reflector 28 in. The reflector was made of plaster paris *P* cast in a wooden box *B*. Wooden strips *S* were nailed in the box in the manner indicated in the drawing to economize on plaster and lessen the weight. The box was mounted on castors so that it could be turned on a platform about six feet in diameter and eight feet high. The steam line projected vertically through a hole in the center of the platform and was connected with a union joint to the valve end *V* of the whistle. This permitted the reflector and whistle to be rotated so that their common axis was in any desired horizontal direction.

The shape of the plaster paris surface of the reflector was obtained as follows: with a focal point on one edge of a board and the edge, the axis of a parabola, a curve was drawn on the board and the half parabola sawed out. With the board radial and its straight edge held against the whistle the board was moved around the whistle and the soft plaster paris "wiped" into position. The focus of such a reflector, if the term focus is permissible, is therefore a circle, and not a point. The focus of any particular portion of the parabolic surface is the nearest point on the focal circle. This focal circle was intended to be coincident with the cylindrical sound source—the cylindrical steam jet, at *J-J*. The length of the steam jet, the distance from the opening to the lip, was two inches. There is a question as to what portion of the jet should be used, or whether some point beyond the lip should be used, as a focal point in adjusting the whistle in the reflector. Experiments were made with the whistle in one position only, quite likely not the position to give the reflector the highest possible efficiency. Nevertheless, the action of the reflector was quite marked.

The curve in Fig. 7 gives the relative intensity of the sound in the 12 directions indicated by the radial lines. The dissymmetry of the curve with respect to the axis in direction one is doubtless due to the fact shown in the figure that the whistle was so placed in the reflector that the lower pitched and louder tone was produced on the side of the axis toward direction two, while the higher and less intense tone was produced on the other side of the axis, in direction 12. Notwithstanding the dissymmetry the curve clearly shows a sound intensity in the direction of the axis of the reflector double that at right angles to the axis and three times that to the rear.

Comparing the result shown in Fig. 7 with that shown in Fig. 1, it is seen that, by placing a locomotive whistle in a reflector in front of the smoke stack the intensity of sound along the track in front of the locomotive was increased to four times its value when the same whistle was located in the position *W* shown in Fig. 1. In direction two the intensity was five times as great. At the same time the intensity at right angles to the locomotive was correspondingly decreased. The maximum intensity could have been changed from direction two to one by rotating the whistle in the reflector.

No doubt the multiplying factor could have been fur-

ther increased had the reflector been made of a material having a higher sound reflection co-efficient that plaster paris.

The placing of a locomotive whistle inside a reflector with its longitudinal axis parallel to the axis of the reflector has advantages other than those already noted. One is, that all parts of the circular steam jet function, which is not the case when the whistle is mounted vertically and the locomotive is running at high speed. This point was investigated by placing a locomotive chime whistle in the usual vertical positon in a horizontal stream of air from a compressor capable of delivering 4,000 cu. ft. of air per minute at a pressure of 100 lb. to the square inch. The stream of air was adjusted to give air velocities at the whistle of 20, 40, and 60 m. p. h. Very little effect was noticed at 20 m.p.h. At 40 m.p.h. the front portion of the whistle, the part against which the air current was directed, functioned rather poorly, the volume of the sound being considerably less than at 20 m.p.h. At 60 m.p.h. it did not function at all, nothing but the hissing sound of escaping steam coming from this portion of the whistle. As the whistle was rotated the character or quality of the sound changed noticeably as one after another of the several tones of the chime was silenced. The steam jet whose vibrations about the lip of the whistle produce the sound, must strike that lip in a particular way to give the best result. When a locomotive is running at high speed the head on pressure and the air currents about the sides of the whistle deflect the steam jet

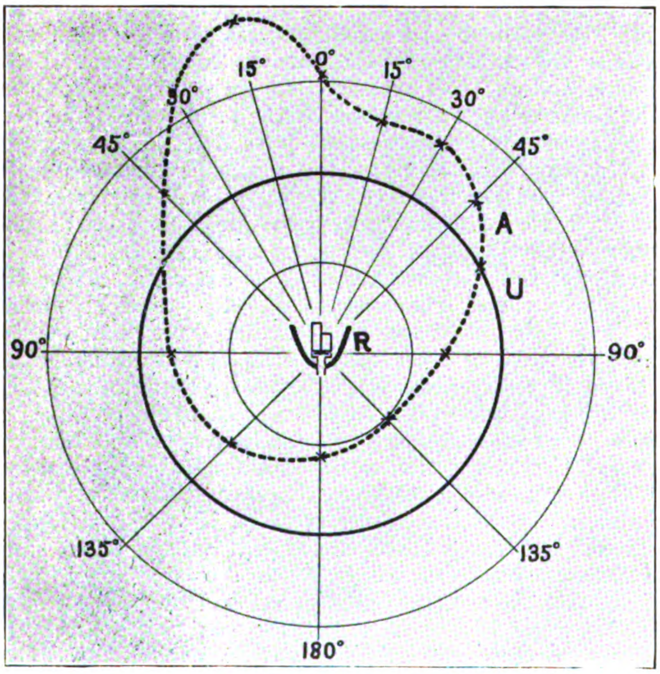

Fig. 7—Sound intensity about a chime whistle mounted in a modified parabolic reflector

so that some portions of it function poorly and others not at all.

The writer remembers a case in court in which a railroad company was being sued for damages because of a crossing accident. Some of the witnesses testified that the engineer sounded the whistle for the crossing and that "it fairly screeched." A "screeching" sound is what one would expect from a vertically mounted chime whistle on a locomotive traveling at a high speed. Let us remember that a wind having a velocity of 60 m.p.h. is normally classed as a tornado. The whistle may fail to function properly at much lower locomotive velocities if the train is running against a head wind. Thus the whistle is least efficient when the train is running fastest and the warning signal is most needed.

In the case of a whistle mounted in a reflector, as in Fig. 6, the body of air about it is carried along with it and the air pressure remains uniform on all sides of the steam jet, regardless of engine speeds or wind velocities. This permits the whistle to function normally at all speeds.

It would seem that locomotive manufacturers have attacked the problem of the inefficiency of locomotive whistles from one standpoint only—that of the intensity of

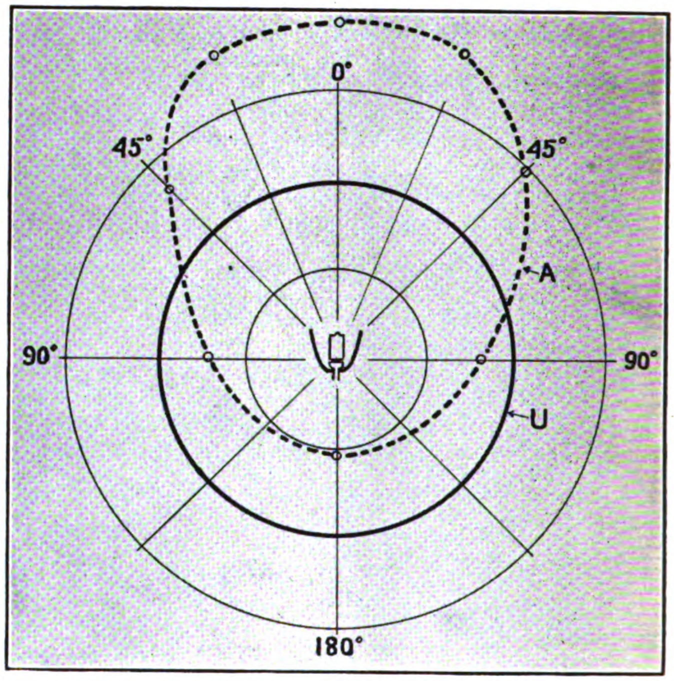

Fig. 8—Sound intensity about a single tone whistle, frequency 1,000 vibrations per second, in a modified parabolic reflector

the sound at the source. They have made their whistles larger and louder, and in order to overcome the objections of people who are disturbed by such intense sounds, they have tried to make the sounds "mellow," as pleasing as possible. It is the writer's contention that this method of attacking the problem is a mistake—for several reasons. I shall mention three of them.

First, we should consider the efficiency of the sound as a warning signal a quarter of a mile, a half mile, in front of the locomotive. We should consider the one to be warned, and not merely the sound source. If the effort to make the sound of the whistle "mellow" and pleasing results in a less efficient signal and consequently in greater destruction of life and property, it is a mistake.

In the second place the increase in the sound intensity of locomotive whistles has necessitated an increase in their size and a consequent lowering of their pitch, a move in the wrong direction. All the information that the writer has been able to get from several psychologists and from his own experiments is to the effect that the human ear is more sensitive to sounds of from 1000 to 1200 vibrations per second than to those of lower frequency. The pitch of the usual locomotive whistle is from one to two octaves too low for efficient signaling.

Another advantage of the higher over the lower pitch is that the former is much more likely to attract attention on account of the sound being unlike the hum of automobile engines and gears, and other usual sounds.

In the third place it would seem that the cost of whistle blowing is an item that has been given little attention.

We have increased the size of whistles with little or no regard to the resulting increase in their operating cost. If this increase had brought about greater whistle efficiency, it would be justified. The expected result has not been realized. A little consideration will convince one that we "pay dearly for the whistle."

According to the company that manufactured it, the chime whistle used in this investigation—a regular locomotive whistle—requires about 8,352 lb. of steam per hour when blown at 200 lb. steam pressure. Locomotive manufacturers say that seven pounds of steam per pound of coal is good average locomotive practice. This means a coal consumption of 1,190 lb. of coal per hour, more than 19 lb. per minute, approximately one pound of coal for every three seconds, or two pounds for every time the whistle is blown—the series of blasts for any signal aggregating, on the average, about six seconds.

The writer by means of a counter and stop watch made several estimates of the time whistles are blown. Observations were made on six different trains on four different roads, in Indiana and Illinois, the trips ranging from 50 to 220 miles in length. Considerable variation was found for different engine crews and for different roads. The average ran something over two minutes per hour. Assuming this figure, a locomotive equipped with the whistle described and operated at the indicated pressure requires some 39 lb. of coal and 275 lb. of water per hour for whistling purposes only.

There are in use on a 24 hour day basis, some 66,000 locomotives, and on the average one-third of these are in continuous use. To blow these whistles on an average of two minutes per hour would require the enormous total of almost 4,000,000 tons of coal and more than 26,000,000 tons of water per year. Why incur this enormous expense if a small high pitch whistle is more efficient and at the same time more economical in operation?

Curve *A* of Fig. 8 represents the sound distribution about a small whistle of the pitch recommended—frequency 1000 vibrations per second. This whistle was mounted in a tin reflector, the relative dimensions of the two being about those shown in the figure. For testing the resonance of the reflector its depth was changed three times by soldering an additional strip of tin an inch wide around the edge. Sound intensity observations were made with each depth. The resonance effect, while appreciable, was not great. It was sufficiently large, however, to warrant taking it into consideration in designing a locomotive whistle sound reflector. It will be observed that the total area of curve *A*, which is proportional to the total sound emission when the whistle was in a reflector, is greater than that of curve *U*, the emission when the whistle was vertical and without the reflector. The effect of the reflector, therefore, is not only to modify the distribution of the sound but to increase its intensity at the source.

The steam required to blow the high pitch whistle whose sound intensity curve is shown in Fig. 8 was 2,500 lb. per hour as against 8,352 lb. for the chime whistle of Fig. 1. This means a saving of 70 per cent of the coal required for whistling purposes, which on the basis of our previous estimate, would amount to some 2,800,000 tons in the United States alone. This is worth considering, not merely from the standpoint of a railroad expense item, but from the standpoint of fuel conservation.

A question that has been raised in connection with whistles of high pitch concerns the carrying power of high pitch sounds. This question is important when considering marine fog signals and steamship whistles, but of little import when designing locomotive whistles. The distance through which the sound of a locomotive whistle must pass is so limited that the difference in the atmospheric absorption of the lower and higher pitched tones may be ignored.

Whistles of the higher pitch are used almost exclusively on the locomotives of England and other foreign countries.

An objection that has been urged against the use of a reflector on a locomotive whistle is that the whistle could not be used to signal to the rear of the train—to recall a flagman, for instance. This objection is not serious. Note, Fig. 8, that the sound intensity in the rear of a locomotive is a little more than half of what it would be if the whistle were vertical and without a reflector. It should be more than sufficient to signal the flagman. It should be remembered that the flagman is listening for the whistle; he is not in a closed car, nor is he disturbed by automobile or other noises.

If it were desirable to increase still further the per cent of sound energy reflected in a forward direction it could be done without destroying the resonance of the reflector by approximately doubling its length. If then the sound in the rear proved to be insufficient for signaling purposes, a second whistle could be mounted so as to face the rear, just as two headlights are sometimes used.

It is a matter of common observation that locomotive whistles on different roads, and frequently on the same road, differ greatly in pitch and in quality. When one hears a whistle, frequently he cannot tell whether it is a locomotive whistle or a factory whistle. He becomes so accustomed to hearing such sounds, that they may call forth no mental reaction whatever. If all locomotive and traction car whistles were of one pitch and others were prohibited from using whistles of that or near that pitch, the human ear would soon come to recognize that tone and instinctively associate it with danger. Not only this, but the volume of sound required to produce a mental stimulus would be greatly lessened.

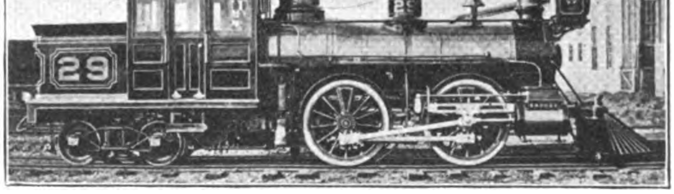
The writer advocates a legal standard pitch for all locomotives and traction car whistles, and legislation that will guarantee railway companies its exclusive use.

Conclusions

Stated very briefly the writer's conclusions are as follows:

1. Locomotive whistles, like the headlights, should be located in front.
2. They should be placed longitudinally in modified parabolic reflectors.
3. The dimensions of the reflectors should be such as to make them resonant.
4. The whistles should be of a frequency of about one thousand vibrations per second.
5. All railway whistles should be of the same pitch, no others being permitted to use a whistle within a half octave of the railway standard.

The writer wishes to acknowledge his indebtedness to H. R. Kurrie, president; J. T. Strubel, master mechanic, and Joe Little, Bloomington yard foreman, Chicago, Indianapolis & Louisville, for their interest in this study and for the railroad equipment placed at his disposal.



An old time tank locomotive of the seventies

Development of foremen

"FROM the comments of 90 separate companies that have had experience in foreman training, 83 express favorable results in no uncertain terms, five express doubtful value and most of these give what they consider to be the reasons therefor, while only two report no success whatever." This statement occurs in the preface of a study on "Foremanship—Fundamentals in the Development of Industrial Foremen"* which is the first of an "Industrial Relations Series" of studies which is being prepared by the Department of Manufacture of the Chamber of Commerce of the United States. Later there appears in the report the significant statement that, "Experience has proven that where the management supported foreman training half-heartedly, even the best methods have failed."

Recent months have witnessed a great demand on the part of railroad officers and foremen for exact information as to just how best to promote foreman training. This survey goes into the entire subject in considerable detail and will be found equally valuable for either the industrial or railroad field, since it deals with methods and practices, rather than details of the contents of the training courses. Some idea of the scope of the report may be gathered from the chapter headings which follow: Word "Foreman" Defined; Purpose of Foreman Training; Beginning Foreman Training; Sources of Instruction; Who Should Direct the Cource; Content of Course; Methods of Instruction; When Should Meetings Be Held; Where Should Course Be Held; Personnel of the Group; Number, Frequency and Length of Meetings; Follow-up; What Does Foreman Training Cost; Sub-Foremen to Foremen; and, What Some Companies Say About Foreman Training. An appendix contains the addresses of state universities which offer foreman training extension courses, as well as the addresses of state departments of education or vocational education, which provide for foreman training under the Smith-Hughes Act.

In the chapter or section on "Beginning Foreman Training," the suggestion is made that some prefer to use such terms as foremanship, foreman conferences or foreman development, rather than foreman training, "on account of the psychological effect of the word training on mature people." This suggestion is well taken in the railway field, because while it is imperative that workers be adequately trained and prepared for promotion to the position of foreman, those who now hold such positions frankly admit the need for help and guidance; indeed, they have in most cases initiated the movement toward that end and have of their own accord organized what is commonly designated as foremen clubs or associations. This chapter includes also rather complete information as to how a large company—the Westinghouse Electric & Manufacturing Company—and a medium sized one—the Corning Glass Works—started their plans for the foremen's development.

In discussing sources of instruction attention is given to sources within the organization and also Y. M. C. A.'s, private educational institutions, federal and state vocational departments, state university extension courses, and other organizations, such as manufacturers' associations, chambers of commerce, etc.

It is important to keep in mind that completion of a course of study in foremanship is little more than the beginning or scratching of the surface. To be really effective, these courses must be followed up in such a way that the foreman will be inspired to keep in touch with the latest developments and to continue his reading and studies along the right lines. Unfortunately the necessity and importance of following up foremanship courses has been recognized to only a very slight extent. One of the most important sections of the Chamber of Commerce report is concerned with a discussion of plans for following up intensive courses or conferences on foremanship. In some cases foreman's clubs or associations are formed and the report gives a typical constitution for such an organization, together with a list of 124 typical topics for papers and discussion at foreman training meetings.

The compiler of this report is indeed to be congratulated for bringing together in so small a compass so much practical and useful information, which is being eagerly sought at this time, not alone by the industries, but by the railroads and public utility organizations of this country as well.

Initial copies will be supplied without charge, but a charge of 10 cents each—the bare cost—will be made for additional copies.

A suggestion for firing locomotives *

By R. W. Karns

Engineer, Cincinnati Division, Pennsylvania, Columbus, Ohio

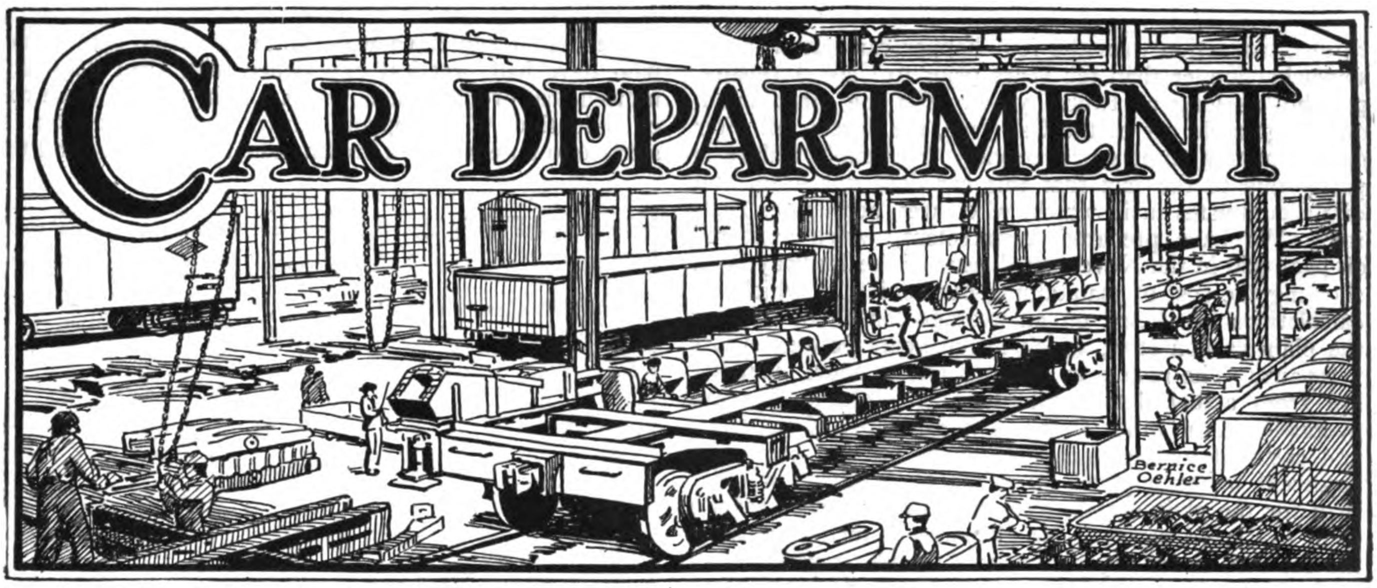
THE proper and what I think the most economical method of firing a locomotive has just been recently demonstrated to us. This system calls for a bank around the door and in both back corners of the firebox, extending forward about 15 or 18 inches. The fire beyond this bank is level and thin. As it requires more pounds of air than coal to manufacture steam, this method permits air in sufficient quantities to pass through the fire, insuring perfect combustion or as nearly perfect as can be had on a locomotive. The engine being drafted so that by maintaining this bank at the door, throwing very little ahead, using three and four shovels of coal at a fire, the draft, so to speak, will pull it ahead as it is needed. This practice lessens the work of the fireman.

This system, in addition to eliminating most of the smoke, insures a uniform steam pressure, and when a uniform steam pressure is maintained the engine can be worked to a greater advantage, the injectors can be better regulated, the superheater will better perform the service for which it is intended, which all means less coal. Care should be exercised at all times to prevent the safety valve raising as this is very wasteful and indicates that the fireman is not watching the steam gage.

In carrying out this system on our run, which is a six to eight car train in one direction and 10 to 12 cars in the other, we are actually doing the job on one-third less coal than the old system and find it much easier for the crew.

The saving of fuel is a big question and simply means co-operation on the part of all concerned. The engineer and fireman must see their work as a partnership affair, work together, keep the question of fuel before them at all times. This is our duty and when we get this spirit into our work, we will have cleaner and more pleasant runs, the service will be better, with less complaint and, most of all, the fuel consumption will be cut considerably.

*Abstract of the prize winning paper on fuel economy submitted in a contest open to engineers and firemen on the Western region of the Pennsylvania.



Rustproofing of steel materials*

Copper bearing sheet steel for cars resists corrosion—Methods of and economies effected by baking paint on passenger and freight cars—Painting with lacquer

By Dr. M. E. McDonnell
Chief chemist, Pennsylvania System, Altoona, Pa.

ENGINEERS now know that commercial steel on the market varies greatly in its tendency to rust. We have made many tests for the purpose of developing resistance to corrosion. On August 1, 1912, 15 weighed commercial steel sheets were exposed to the weather and on February 13, 1913, after six and one-half months exposure, they were wire brushed and re-weighed. It was found that the rate of rusting varied much, the minimum loss being 30.12 grains and the maximum loss 84 grains on the two sides of a square foot of surface. The results are shown in the curve in one of the illustrations and it is to be especially noted that the sheets showing the lowest losses in weight, contained copper. The curve on the plot shows the copper content. This heretofore unpublished chart was prepared in 1915, and it was largely instrumental in bringing about the decision of the Pennsylvania management to adopt copper bearing steel for car roofs.

Additional tests were made of a lot of 258, 16-gage and 230, 22-gage sheets of plain carbon and copper bearing steel which were placed in test racks and exposed to the elements. After 16 months of exposure 30, 22-gage plain carbon sheets failed while no copper bearing sheets failed. After 28 months exposure, the number of 22-gage plain carbon failures had increased to 77 during the same period only six 22-gage copper bearing sheets had failed. Some of the panels had entirely turned to rust. After 75 months exposure every plain carbon steel sheet had failed, while 13 copper bearing 22-gage sheets were free from holes or ragged edges. Also, at the end of that period, 102 of the 126, 16-gage plain carbon steel sheets had failed, while there was not a single failure among the 132, 16-gage copper bearing steel sheets. The average life of the copper bearing 22-gage sheets on this test was over 49 months, while the average life of the 84 plain carbon steel sheets was 23 months.

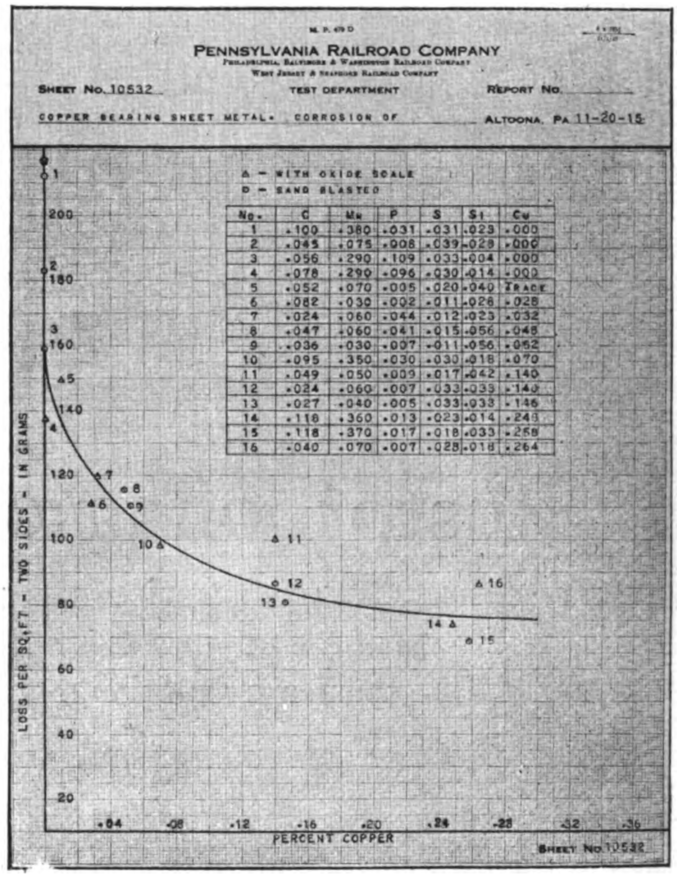
The Pennsylvania System has some 269,000 freight cars, of which 266,588 are of steel construction, 167,398 of these being steel throughout. These steel cars are of different weight and design. There are approximately 32,000 all steel box cars, on which the rate of depreciation due to rust is not yet definitely known. They can be protected against rust by means of paint coatings to a much greater extent than an open car which is used for rough freight, and the roof protects the inner side of the plates. No attempt will therefore be made to estimate the value of copper bearing steel for this class of cars.

There are 135,523 open all-steel freight cars on which much maintenance data is available. After they have been in service for a number of years, the sheets become thin and holes develop. When they have reached this condition, it is possible to patch the failed sheets, but if this is done, the surrounding sheets are likely to fail and the cost of this kind of maintenance is likely to become excessive. When failure of sheets begins to occur due to rust, it is better to apply Class 1 repairs, which involves cutting all rivets, removing sheets, and rebuilding the car body. The age of the car at which this class of repairs is called for varies some, depending on design and service. The standard four-hopper coal car designated H21a now required this attention after ten years of service. The two-hopper coal cars of the G1 type is of slightly more

*Abstract of paper presented before the regional meeting of the American Society of Mechanical Engineers, held at Altoona, Pa., October 5, 6 and 7, 1925.

rigid construction than the four-hopper car. It will run somewhat longer than ten years prior to Class 1 repairs, possibly as long as twelve years. On the other hand, on the gondola car of the Gsd type, the sheets fail after approximately eight years' service. This rapid failure is partly due to the fact that this car does not drain and dirt accumulates in it, which, when wet, accelerates rusting. We have prepared a statement, which appeared on page 850 in the November 7 issue of the Railway Age, showing the cost of maintaining car bodies, in which the calculations are based on an average length of life for the plain carbon steel, which is ten years between Class 1 repairs. The results in columns one to four, inclusive, are from actual data, while those in column five are averages of the other four. The estimates of materials and costs of maintenance for copper bearing steel cars represent an anticipated 50 per cent greater durability than for the plain carbon steel cars, or a 15 year service prior to Class 1 repairs. No allowance is made for painting the cars or for any repairs to the underframes, trucks or brake equipment. The increased cost of cars due to the use of copper bearing steel is shown. This is obtained by applying the differential of $3.00 per ton which has prevailed between plain carbon and copper bearing steel plates. This amount may diminish when the amount of copper bearing scrap now being used by the steel makers is increased. In making the calculation, allowance is made for losses in fabrication caused by shearing and punching. It is shown that the 135,523 cars involved would have cost $2,509,295.86 more if they had been made of copper bearing steel. The statement shows the amount of new finished plates, shapes and rivets, as well as the cost of material and labor, including shop expenses, required to dismantle and rebuild car bodies. If these cars are given Class 1 repairs over a period of ten years, using plain carbon steel sheets, the annual cost under present market conditions amounts to approximately $5,069,112.04. From the experimental data at hand to date, it may be assumed that with the use of copper bearing steel, the interval between Class 1 repairs will be extended over a 15-year period and repairing with copper bearing steel sheets reduces this cost to approximately $3,473,710.30. This represents an annual saving of $1,595,401.73 and an annual reduction of 22,385 tons in the amount of new steel required.

Those who have not given this subject special study may wonder why copper is a protective measure and what connection it can have with protective coatings. Those who have had practical experience with steel may have noticed that ordinary steel forms a light brown, loose rust on oxidation, while copper bearing steel oxidizes on the surface to a dense, dark brown, adherent coating, and this

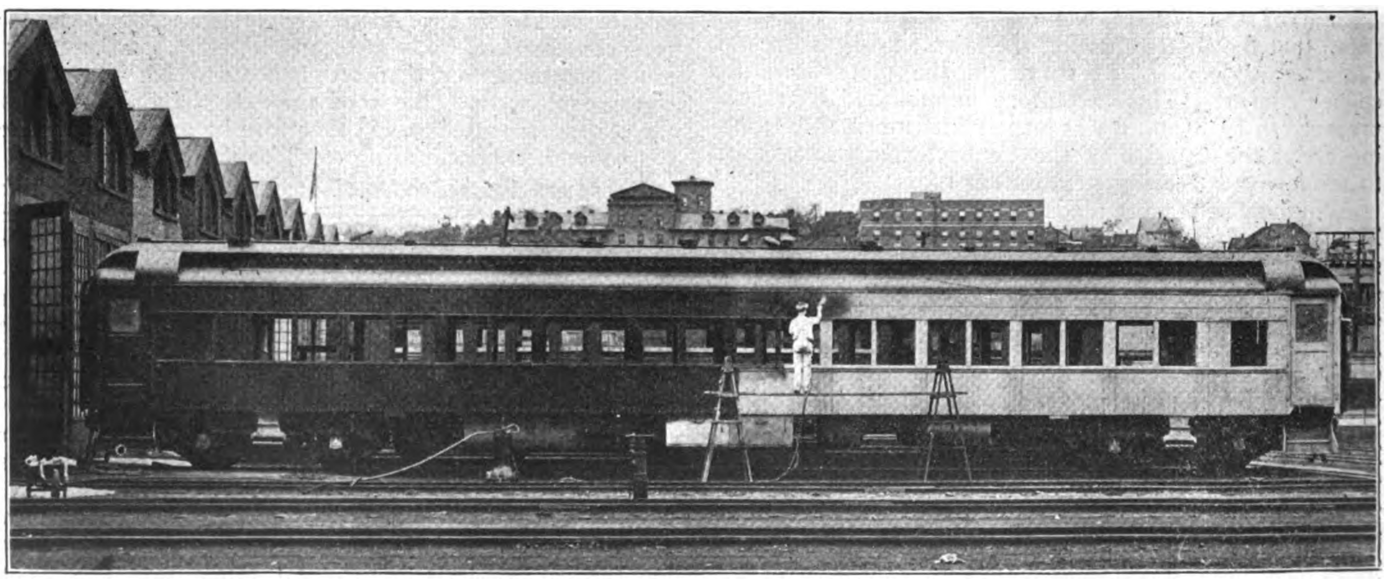


Variations in the rate of corrosion of steel

is believed to act as a protective measure against rapid destruction.

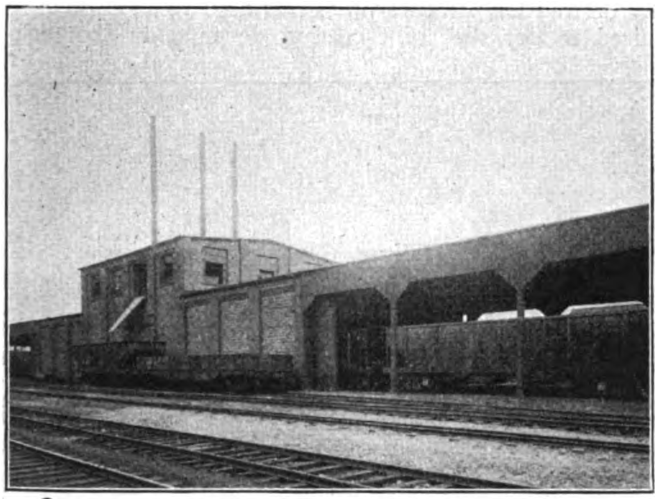
Method of protecting the surface of construction steel

The duties of the engineer do not end with the purchase of the best commercial structural metals now available. Steel for important structures, such as bridges, should



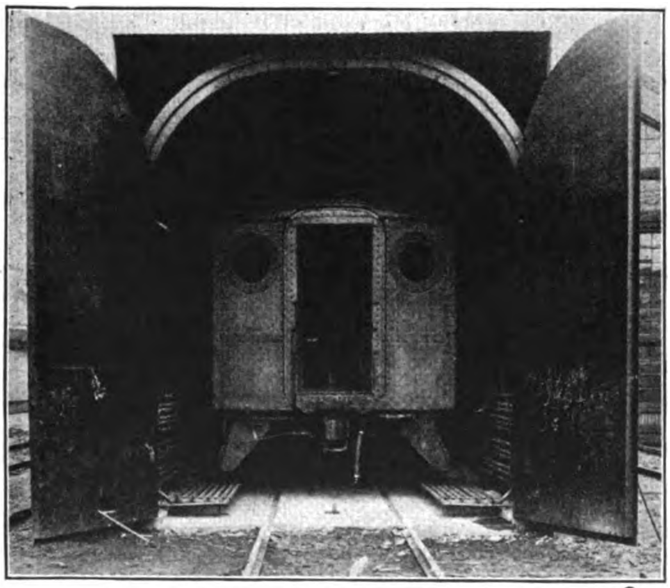
Applying Tuscan red lacquer finish to a car

receive a shop coat of good paint prior to its shipment from the factory and for this purpose red lead is still a favorite. Steel for rolling stock which is not painted should be stored in a dry place until it can be assembled and if this is not feasible a protective coat of some kind should be applied. The method employed by the Pennsylvania System, and we believe by numerous other concerns, is to apply a petroleum oil coating which contains resins and wax, these constituents being added to the oil for the



Baking ovens located at the Pitcairn car shops, which turn out 23 freight cars every 16 hours

purpose of imparting adhesive properties. On withdrawal of the steel from storage for use, the temporary protective coating is removed. After construction, exposed steel parts should be well painted. Many technical organizations, including our research staff, have devoted a large amount of work towards determining the most durable paints which can be applied. Experience teaches us that

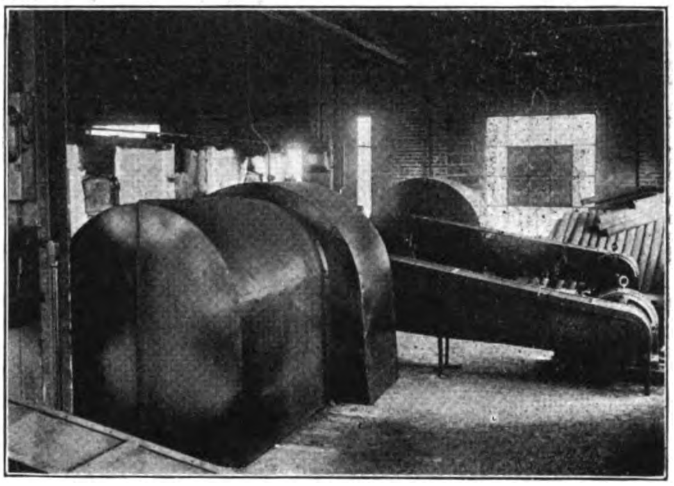


Baking ovens first designed and used at Altoona, Pa., 1913

the best air drying paints are those which contain suitable pigments, good oil and a minimum amount of drying constituents, such as Japan drier. Paints made in accordance with these precepts, dry slowly, and under conditions prevailing in industrial centers, the coating is likely to become contaminated with dirt before the paint film is set. Furthermore, the use of such paints on rolling stock keep it in the shops and out of service. Painters know that an excessive amount of driers shortens the life of paint. The action of the driers does not cease when the paint film has become dry, but continues after the purpose for which they were added has been accomplished. This leads to premature destruction of the paint film and while the fact is generally known, we have confirmed it by panel tests. Notwithstanding the known detrimental effect of these driers, painters sometimes use them in excess in order to get the equipment out of the shops in the shortest time possible.

Baking paint on passenger equipment

A laboratory baking oven was constructed and a large number of painted panels prepared, using different compositions. These panels were exposed on a test rack in comparison with panels painted with the usual air drying paints and varnishes in use. The panel tests showed that the baked coatings had greater durability than the air dried ones. The difference was so decided that a baking oven for passenger cars was constructed at the Altoona paint shops. The first car painted by the baking process was finished in January, 1913. One of the illustrations shows the exterior of this car after 40 months'



Fan and hot air furnace which supply the Pitcairn baking ovens

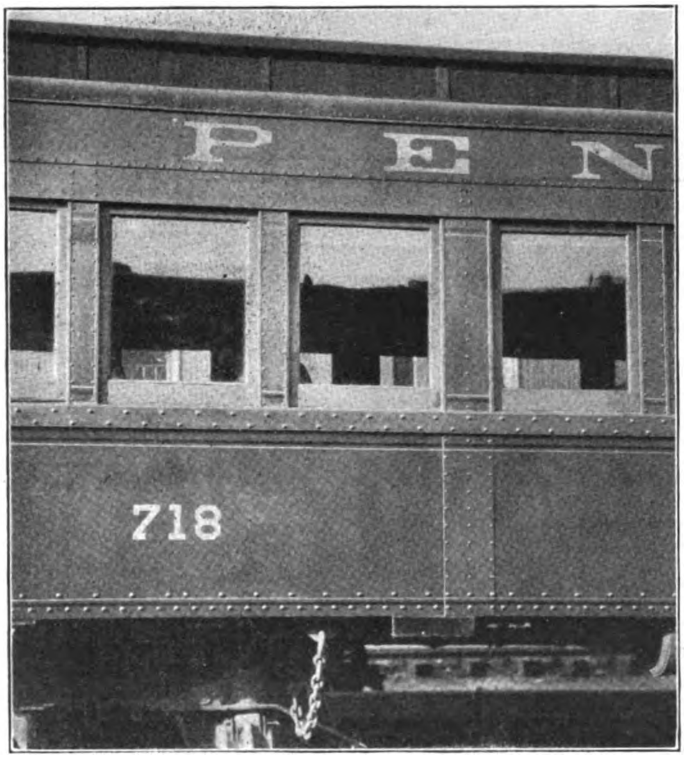
service. The paint was in good condition. Another illustration shows a car painted by the baking system in November, 1913, and photographed September 22, 1925. During this period, the car was in the shops for baking class repairs at three different periods. No color or varnish has been applied to it since June, 1923. These class painting repairs consisted of one coat of color and two coats of varnish to the exterior, and one coat of varnish to the interior. Cars painted by the baking process require class repainting every 36 months, while those painted by the air-dry process receive class repainting at intervals of 18 months. It requires 14 working days to paint a new passenger car by the air drying process, while by the baking process all of the painting operations can be applied in six working days. The baking process reduces the time which passenger cars must be retained in the shops on account of painting operations more than 60 per cent. There are now three baking ovens in service. One of them is illustrated which is 90 ft. 3 in. long, and will accommodate the largest cars in service. They are equipped with ventilators, and are heated by steam under a pressure of 125 to 150 lb. Each oven contains 2,000 sq. ft. of radiating surface. Temperatures of 250 to 260 deg. F. are obtainable. Baking paints, also the priming

and surfacing coats for passenger equipment cars, are dried in three hours at these temperatures. Varnish and light colored enamels used for the final coats on passenger cars darken at high temperatures. In practice they are dried in three hours at temperatures of 150 to 160 deg. F.

The coatings as applied to passenger cars by this method have been found to be very durable. All steel passenger cars from which it is necessary to remove the old paint are sent to Altoona, Pa., to be repainted by the baking process. All cars painted by the baking process are marked, and when they require class painting repairs, the additional colors and varnishes applied are dried in these ovens.

Baking paint on freight cars

In addition to the baking of paint coatings on passenger cars, the method was applied to some 1,100 freight cars in 1913. These were coal cars which were in need of paint. They were given one coat of baking paint in which different oils were used, including Menhaden fish, corn, cotton seed and soya bean oils, with linseed and China wood oils. None of the paints used contained artificial driers. The paint on these cars was dried in an oven at South Amboy which was used for thawing cars of frozen coal which were to be dumped into boats. The temperature obtainable was 185 to 195 deg. F. and it



Car finished by the baking process November, 1913—Photographed October 22, 1924

required six or seven hours to dry the paint. The cars were repeatedly inspected for about five years and the results obtained were so satisfactory that baking ovens were authorized and built at the Pitcairn car shops in 1923.

The Pitcairn installation is shown in one of the illustrations. It will be seen that they are different from the Altoona ovens previously described. There are three units over parallel tracks, each of which will accommodate three freight cars at one time. Each unit is provided with a coal-fired hot air furnace containing 40 tubes through which air is circulated by means of fans. The air to be heated is drawn from the top of the baking oven, passed through the tubes of the hot air furnace, and forced back to the bottom of the ovens through suitable ducts. The circulation of the air from the ovens through the furnace is continuous. However, provision is made for a little ventilation. A vent is provided for discharging some hot air from the top of the ovens to the atmosphere, and this loss is replenished with fresh air which is drawn through an intake into the plenum chamber of the fans. The furnace, the fans and the motors which operate them are illustrated herewith. These ovens permit the control of any desired temperature up to 360 deg. F. The time required to dry the paint coating depends on the temp-

Condition of the exterior panel of the first car finished by the baking process after 40 months' service

erature. If the ovens are operated at 225 to 250 deg. F., the painted cars are allowed to remain in them for three hours, and at 275 deg. F., the time is reduced to two and one-half hours. Thirty-two cars are now painted daily at Pitcairn. Each car receives two coats of paint, both of which are baked from two and one-half to three hours, after which they are stenciled. The paint is sprayed on, and two shifts of painters perform the work. It is possible by this method to apply two coats of paint and stencil the cars in one full working day after the cars are delivered to the paint shed, it being understood that due to two shifts of employees, a working day is 16 hours. No artificial driers are added to the paint used and a large percentage of Menhaden fish oil is used in thinning the paste paint, which is ground in linseed oil. A small percentage of China wood oil is used, as our tests and experience indicate that this addition increases the water resisting properties of the paint film. It is estimated that the time saved in painting cars by this operation is two days. In other words, the cars are available for two more days revenue service. By this method of painting cars, unexpected delays due to failure of the paint to dry on account of bad weather conditions is not experienced. The method will likely be extended to other shops.

Lacquer method of painting equipment

The extension of the baking system for passenger cars to other shops has been deferred pending the outcome of tests which are being conducted with the lacquer system which has recently revolutionized the method of painting automobiles. These lacquers contain a colloidal solution of nitrated cotton and varnish gum in a mixture of volatile solvents, which usually include ethyl acetate, anhydrous alcohol, benzene or toluene and other volatile constituents. Pigments are incorporated with this solution to give the

desired color, and to make the resulting film durable. Lacquers of this type dry so quickly that they cannot be satisfactorily applied by means of a brush. They are applied with spray equipment. The Pennsylvania System now has five passenger equipment cars and over 100 locomotives which were finished with lacquer. The operation of finishing the exterior of a passenger car with tuscan red lacquer is shown in one of the illustrations. The exterior of a car can be coated without difficulty. There is some trouble in finishing the interior of cars due to the fact that several colors are used. If the headlining is to be light green, the body of the car bronze, and the base dark green, any one of the colors can be applied, but in the application of the adjoining color by means of a spray gun, it is difficult not to spoil the first color applied. Another difficulty is encountered if it is desired to apply gold striping or lettering over a lacquered surface. The gold must be protected, and this is now done by pencil varnishing it. This is a time consuming operation. The lacquer coating can be quickly applied and successive coats can be sprayed at intervals of about 30 min. Means will probably be devised for overcoming the present difficulties. When properly made, applied and polished, these nitrocellulose base coatings present a pleasing effect suggestive of refinement. Lacquer finishes can be cleaned more easily than the more familiar varnish coatings.

The progress in the development of rust preventives has been rapid during the past decade. The successful engineer must ever be alert to the end that his client may receive the benefit of the best information obtainable.

Decisions of the Arbitration Committee

(The Arbitration Committee of the A.R.A. Mechanical Division is called upon to render decisions on a large number of questions and controversies which are submitted from time to time. As these matters are of interest not only to railroad officers but also to car inspectors and others, the Railway Mechanical Engineer will print abstracts of decisions as rendered.)

Interchange Rule 32 again upheld

On January, 1923, St. Louis, Troy & Eastern empty coal car No. 1034 was being handled in switching service by the Chicago, Rock Island & Pacific, during which time it was broken in two while making a coupling. The car owner received a request from the handling line for a disposition of the damaged car to which was attached an inspection report which in substance showed that all of the eight sills were broken in 32 different locations and that the car body was practically demolished. It was estimated that it would cost approximately $1,000 to repair the car. The car owner sent several inspectors to examine the car and after receiving their report, advised the handling line that in its opinion the car had received unfair usage and agreed to settle according to A. R. A. Rule 112. On March 29, 1923, the Rock Island refused to handle the car according to Rule No. 112 and stated that the damage was due to decayed side sills. On April 12, 1923, representatives of both companies made a joint inspection of the car body after which both agreed that the eight side sills had been broken in 32 different places. The car owner based its contention of unfair usage on the fact that the body of the car had been turned over on to the opposite track although the trucks still remained on the track. This indicated that the car had been coupled on at a speed exceeding the limits of safety, which constitutes unfair usage according to A. R. A. Rule 32, Section D. The handling line stated that the car had not been subjected to unfair usage for according to testimony by the engine and yard crew, the coupling was made at a speed of from two to four miles per hour. There were no other cars damaged at the same time, neither was car No. 1034 or any other car derailed. The car failed owing to the fact that the sills were decayed on top in the center which was not fully disclosed until the decking had been removed. With these facts in mind the handling line took the position that the damage occurred in ordinary switching and inasmuch as the car was not derailed, cornered, sideswiped, or subjected to any other unfair usage as defined in Rule 32, the car owner should furnish disposition in accordance with Rule 120.

The Arbitration Committee rendered the following decision, "There is no evidence that the car was subjected to any of the unfair usage conditions of Rule 32. The car owner is responsible."—*Case No. 1338, St. Louis, Troy & Eastern vs. Chicago, Rock Island & Pacific.*

Labor charges for testing and adjusting steam coils on tank cars

The Pierce Oil Corporation, at its Sand Springs, Okla., plant, tested and adjusted the steam coils in A. T. & S. F. tank car, No. 96064 and in 17 other cars and submitted a bill for $30.45 to cover labor charges. The owner requested cancellation of these charges claiming that the work should have been considered inspection and under Rule 108 of the 1920 Code of Rules, no labor charge should have been made. The handling line stated that the tank cars were sent to its refinery for fuel oil loading and in accordance with I. C. C. regulations, Section 2, Article 1822E, the tanks and fittings of these cars were inspected and found to be in a defective condition due to leaks, making it necessary to tighten up loose and leaky connections. The handling line further contended that it was in no way responsible for the leaky condition of the cars and that Rule 108 applies only to ordinary train yard inspection and has no bearing on inspection or repairs to the parts in question.

The Arbitration Committee in rendering its decision stated that, "Rule 108 prohibits a labor charge for inspection of cars, tightening unions, etc. Therefore, the bill of the Pierce Oil Corporation should be withdrawn.—*Case No. 1339, Atchison, Topeka & Santa Fe vs. Pierce Oil Corporation.*

Labor charges for application of wood end posts with metal fillers

The Illinois Central rendered the following bill to the Southern Pacific for the application of wood end posts with metal fillers:

2 wood end posts at 5.5 hr. each, total	11 hrs.
2 metal end posts filler plates	
20 metal end posts filler plate bolts at 0.2 hr. each	4 hrs.
Total	15 hrs.

The Southern Pacific took exception to this bill on the grounds that the four-hour charge was excessive for applying the metal plates to these posts. It further contended that the labor charge for applying these posts is based on the material charge for lumber for the posts and wrought iron for the fillers which contemplate the framing of these posts and according to Rule 107 the labor allowance for the application of posts to cars includes all work necessary to complete each item of repair unless the rules provide that additional labor may be charged, and that as Rule 107 does not provide additional labor for the

application of fillers and as the item of repairs is not complete until these plates are applied, the arbitrary charge of 11 hrs. cannot be exceeded. The Illinois Central contended that the bill was correct in accordance with Item 249 of Rule 107, inasmuch as it does not list such bolts among the items intended to be included in the labor charge of 4.4 hrs. for a post. Furthermore, because few companies have their cars equipped with end post plates, the Illinois Central maintained that the committee omitted the charge of 4.4 hrs. for end posts renewed, and that therefore, the Southern Pacific's reference to the first paragraph of Rule 107 has no bearing whatever on the question.

The Arbitration Committee in rendering its decision stated that "The total labor charge should be reduced to 11 hours, which is the average allowance permitted in Item 249, Rule 107 of the 1921 Code.—*Case No.* 1341, *Southern Pacific vs. Illinois Central.*

Interchange inspectors' discussion of new rules

Report and discussion of C. S. Cheadle's paper on the prevention of transfers and claims arising from transfers also included

Aside from the presentation of papers, abstracts of some of which have been published in the two preceding issues of the *Railway Mechanical Engineer,* the second and the last day's sessions of the Chief Interchange Car Inspectors' and Car Foremen's Association convention held at Chicago, September 22, 23 and 24 were devoted principally to the discussion of new interchange rules. These rules are abstracted in this issue, together with a highly constructive paper on the subject of transfers and the claims arising from them, by C. S. Cheadle (R. F. & P.).

Prevention of transfers and claims arising from transfers

By T. S. Cheadle

Chief car inspector, Richmond, Fredericksburg & Potomac.

The transferring of carload freight affects the service expected of railroads and causes losses of revenue to shipper or consignee as well as the railroads. It affects all departments of a railroad to such an extent as to demand the careful attention and co-operation of every one having to do with shipments in an effort to reduce the enormous loss suffered as a result of transferring the load enroute.

The transfer problem on the railroads is as old as their institution and was the main factor in bringing about standardization of track gage and car parts. There are a number of men in railroad service today who remember changing car trucks at interchange points to prevent transfer of passengers and freight and expedite movement of cars.

In the table is shown the result of a check of cars transferred from January 1, 1925, to June 30, 1925, inclusive, by the railroad with which I am connected. The transferring was done in connection with interchange of cars by seven Class I truck line roads under point arrangements and no doubt represents the average condition under A. R. A. Rules of Interchange.

It will be noted that more cars were transferred on account of conditions over which the mechanical department had no control than for ordinary wear and tear mechanical defects.

No way has been found to overcome the loading of house cars which are too high and wide. A card has been printed, worded as shown in Figs. 1 and 2, with the dimensions shown on the opposite side for routing through the Potomac yard gateway. For some time these cards have been attached to all cars when empty on our road. This was done with the view of informing agents, inspetcors and shippers of the unsuitability of cars for shipments routed through the Potomac yard gateway. If

Fig. 1—Front of card applied to cars too large to pass through the Potomac yard, R. F. & P.

it could be arranged to stencil all cars which exceed the standard dimensions, it would be a great benefit. However, under Car Service Rule 14, the receiving line is chargeable with the cost of transfer and unless this is made a loading line responsibility some will continue to load such cars.

The matter of cars being transferred on account of being unsuitable for perishable commodities which do not require icing; that is, ventilated cars loaded instead of refrigerators, is being handled by a special committee and test is being arranged to determine the suitability of the ventilator car as compared with a refrigerator car, where icing is not required.

The cost of transferring overloaded cars is chargeable to the delivering line; however, cars often pass several interchange points before being stopped. It should be made a loading line responsibility. This would often result in cars being delivered without being transferred.

No rule can be devised that will overcome the necessity of the mechanical department closely supervising or having charge of the transferring of cars. In every case, a

thorough inspection should be made by a competent inspector, one who is thoroughly familiar with shop track work and who is capable of using sound judgment in deciding whether a car should be repaired or transferred. Where this is not being done, if adopted, it will overcome a large number of transfers now being made.

Mechanical defects causing transfer are the result of poor design, improper construction, rough or improper handling (largely from use of the independent air brake), failure as the result of age, due to decaying, corroding, or wearing out and breaking as the result of fatigue, the misuse of the car in loading a commodity for which it is not suitable, improper loading and leaking tank cars.

11	3	11	0	10	6	11	0	10	6	11	0	10	6

The equivalent width is the doubled distance from the center line of track to an outside point in line with widest part of car. Height, is from top of rail to highest point of measurement.

Fig. 2—Reverse side of the card shown in Fig. 1

Tank cars should be tested under oath to prevent a car being stencilled and put in service without proper test having been made.

The present standard and recommended designs, deserve the praise of all car men. Nevertheless, there is considerable shop track practice in rebuilding and repairing that should be avoided or condemned. Poor repairs are nothing but an expensive bad habit and often good permanent repairs can be made for less than a patched up botch job.

With the varied standard of inspection, the present rules are ideal for creating transfers. Any change in rules would help to prevent them. However, it is logical to suppose that a rule which should make the car owner or loading line responsible for transfer costs on account of ordinary wear and tear, would be progressive and equitable; it would leave it to the judgment of the car inspector as to whether a car was safe to reach the next point of inspection. If the owner was responsible, it would make it profitable that the car be kept in repair.

At the same time the cost of switching and per diem would penalize the carrying line sufficiently to cause the movement of the car without delay and would result in the owner being willing to permit and accept charges for temporary repairs rather than to pay the cost of transfer.

The majority of car men will agree that an inspector has exercised good judgment and performed his duty properly when he passes a car safely to the next point of inspection. This, however, cannot be done under the present rules without penalizing his line, and the inspector has to anticipate what will be the judgment of inspectors at every interchange point which the car will pass en route to destination, and in doing this cars are shopped and transferred which should run. This brings about a point of view that "if you will not, I will not." This also applies to improper loading, use of small stakes and tie boards, and improper bracing.

A rule that would give chief joint car inspectors, or some competent car man where there is no joint inspection, at principal gateways, the authority to route a car home to the owner when in need of rebuilding (Car Service Commission to enforce repairing of car) would prevent

the loading of worn out cars more than any one thing and would increase greatly the average miles per day of loaded cars. In addition, the definition of a serviceable empty car should be changed to read, "A car suitable for any commodity for which it is intended to be used." And for a loaded car, "One which will carry its load safely to destination." This is necessary for the reason that it is rare in interchange that an inspector knows what the car will be used for when it is loaded. He, therefore, has no opportunity to exercise his judgment.

A summary of things that would prevent transfer includes equipment of good design and construction; substantial repairs to old equipment; a change in rules which will enable inspectors to use their judgment as to the safe movement of the car; a rule which will make it profitable for the handling line to run the car and also make it

Fig. 5—The reverse side of the record card is a continuation of the information for the claim department

profitable for the owner to repair, adding a rule by which worn out cars can be sent home for repairs, and giving a definition of an empty car which will work in interchange.

The prevention of claims as the result of transfer is a very hard matter to overcome, as it appears that the consignee almost invariably accepts the knowledge that transfer was made as an invitation to make a claim.

It is thought by a good many mechanical men that claim departments deal too largely in a stereotyped manner, in securing information by the use of forms, widely distributed, among men who often carelessly furnish information which is not based on a knowledge of the facts and the consignee is sometimes furnished with information which encourages claims.

The prompt handling of a car shopped for transfer is one of the most important points in connection with this subject, as delay increases the possibility of a claim. When a car is shopped for transfer, a stiff conspicuous tag, as shown in Fig. 3, should be attached to the car. The car should be placed promptly, together with a car in good order. The latter should be a good looking car as it is human nature for the consignee to be affected by the looks of the car in which the load is received; transfer tracks located conveniently to the switching territory, properly spaced, will add materially to the quick transferring of the car. Proper supervision of the transfer forces is another of the most essential things in connection with proper handling of the commodity and a record should be made correct in every detail for use of the claim department, such as is shown in Figs. 4 and 5. Extreme care should be exercised on practically all commodities to see that they are placed in the receiving car in a manner as near as possible like they were when originally loaded, if this loading was properly done, and that proper bracing and door protection is afforded, if necessary. Gum shoes, clean gloves and hands should be used in connection with careful handling of dressed or fine lumber to prevent marking, defacing or injuring tongues or grooves; hooks and canthooks should not be used where it will injure lading. Watermelons, canteloupes or such commodities should be topped as near like the original load as possible. Baskets should be provided for handling bulk apples, oranges or such fruits, that are liable to bruising in handling. A record should be required of yard and mechanical forces showing the delay and its cause in handling cars for transfer.

Statement of cars transferred, showing the defects making such transfer necessary and the total cars handled in interchange by the R. F. & P. with the A. C. L., B. & O., C. & O., Penna., S. A. L. and Southern from January 1 to June 30, inclusive, 1925.

It appears that no accurate data have been compiled to show loss as the result of transferring cars. It is estimated by various sources that all cost considered, losses will average $60 per car. Under any condition the cost is high, and the management of railroads, when they fully realize the effect, will apply a remedy.

Discussion

Mr. Campbell: I heartily agree with Mr. Cheadle's paper. I think it would be beneficial to the railroads to spend more money to repair cars rather than to transfer and especially with many commodities that are liable to damage claims, like automobiles. At Minneapolis, we make it a point not to transfer automobiles. We are spending $50 to $60 a car to avoid it. If the railroads will do more of this thing, they would get away from a lot of claims.

Mr. Hanson: I would like to ask Mr. Cheadle who handles the cards which he showed here, the joint inspector or the transportation department?

Mr. Cheadle: All the cards are handled by the inspector with the exception of the cards issued for overloading, which are filled out by the transportation department man and forwarded to the man who loaded the car. The mechanical department has supervision over the transportation department on the transfer tracks.

Mr. Trapnell: I would like to ask Mr. Cheadle when he transfers a car for transferable defect what disposition he makes of the empty?

Mr. Cheadle: About 50 per cent of the cars we repair ourselves and about 50 per cent are returned to the delivering line.

Mr. Trapnell: In the month of March, 1925, we transferred 462 cars out of 125,425 interchanged. I find that out of the 572 transfers asked for we refused 110. The number of cars repaired out of 462 was 81; number of cars not repaired, 381; number of cars not repaired and loaded out from point where they were transferred, 96; number run out empty to go out and get other loads, 114; number stored for repairs, 73, and number moved home empty, 76. Cars that should have been repaired by the receiving line in 20 or more hours were 258. We are throwing away the money of the railroad companies which we represent by the wholesale when it costs us 25 cents a minute to switch the car; in addition we frequently have to pay per diem for the car while it is held, to say nothing about loss and damage freight claims.

Discussion of freight car rules

Rule 2

The committee recommends that Bureau of Explosives' Pamphlet No. 20-J be incorporated in the next issue of the rules as an addendum for the information of car inspectors, with a designating mark opposite Section (b) of Rule 2 calling attention to same.

The committee recommends that second paragraph of Section (h) be modified as follows:

Proposed Form—For inside door protection, *side or end*, the car transfer check, issued by the road having car in its possession, shall be authority for bill against road on which load originated, for cost of adjusting load due to absence of, or improper inside door protection, as well as cost of applying or correcting such protection. (See Section (e) A.R.A., Car Service Rule 14.)

Reason—To harmonize rule with action of joint conference between Mechanical and Transportation Divisions.

T. J. O'Donnell (Buffalo, N. Y.): Is it understood by all that the rule would apply to a small end door window or would it apply only to an end door?

T. S. Cheadle (R. F. & P.): It has been my impression that it would apply to any end door.

Mr. O'Donnell: How are you going to hold the loading road responsible and how are you going to charge for

the cost of adjusting the load, due to the absence of proper inside door protection?

Mr. Cheadle: By what our committee rules, I think the delivering line really stands for any small end door protection that we have to apply.

Mr. O'Donnell: Will the delivering line understand that the charge is for any end door?

Secretary Sternberg: In my opinion Mr. O'Donnell is correct. I do not think the intention is to go so far as the small end door.

Mr. Cheadle: It is my position that it would apply only to vehicle door but as the rule reads it would apply to any end door; I do not think in the case of some kinds of lading they would insist upon protection against the end door.

C. J. Nelson (C. I. E., Chicago): It is my opinion that the rule as it is now written will probably only be applied to the vehicle cars, in the majority of cases. I think that Mr. O'Donnell probably has in mind the small end door which is being used on cars today but there is a possibility of end doors of different design being applied to cars in the future and it seems to me it does no harm to include small end doors. There are times when the shipper really should cover the end door when he puts certain kinds of loading regardless of how small it may be and as I understand it the labor charge is actual and cannot be a great burden to anybody, to render a bill against the originating line for necessary protection on the small door. I quite agree as to the necessity of having to remove the load on many occasions to apply this end door protection which may not amount to a great deal, but I see no reason why the receiving line should assume that expense and it seems it would be very well to take the rule literally.

G. Lynch (Cleveland, O.): I think the proper method of procedure would be to make a motion to refer this matter to the Arbitration Committee for decision.

F. W. Trapnell (Kansas City, Mo.): I move that it is the understanding of this body that the rule includes any end door. The motion was carried.

Rule 4

The committee recommends that the second paragraph of this rule be changed as follows:

Proposed Form—Defect cards shall not be required for any slight damage (new or old) that of itself does not require repairs before reloading of car, *except that the car may be used, under load, in movement to shop for the required repairs.*

Reason—The recommended modification is a reasonable exception to the general rule, which contemplates that cars with defects requiring repairs shall not be continued in service indefinitely. The general restriction against reloading defective cars is advisable as a measure against the improper issuance of defect cards for unnecessary repairs.

With reference to second sentence of present rule, the experience has been that in many cases it is practically impossible to determine whether the defects were new or old.

Mr. Bell: It occurs to me in connection with this, that a car might be unloaded and reloaded before it returns to the owner, so that the wording of the rule gives the owner no protection in that case.

Rule 8

G. P. Zachritz (M. St. P. & S. S. M.): The note after Rule 8 which refers to the changes in the billing and wheel repair cards and provides that the present repair card (used at that time) may be used until the supply is exhausted. The note contemplated that when that supply was exhausted the roads would supply billing repair and wheel repair cards as shown on Pages 199 and 201 of A.R.A. Rules effective January 1, 1925.

Some of the roads are still buying repair cards and wheel repair cards which are not standard. Some of them have an additional column headed "money," and instead of using the "net price" column for all items expressed in money they divide the items between the "net price" and money columns.

Some of the roads do not put the prices on the wheel repair card and some of them bunch the price of the wheels, the axle and the labor of applying wheels and carry it to the money column on the repair card which necessitates the car owners repricing the entire repair in some instances.

I suggest that the Arbitration Committee ban the use of non-A.R.A. repair and wheel repair cards and where cards are not priced in accordance with the instruction as per the different headings on the billing repair card and wheel billing repair card, it be left to the option of car owner or company billed whether to reprice and check the bill and voucher same or return it to billing line to be properly priced.

Rule 9

The committee recommends that the information to be specified on billing repair cards after item of Brake Beams, R. & R., be modified as follows:

Proposed Form—New or second-hand, applied. If A.R.A. and number of same, or non-A.R.A. Cause of removal. Location number (see Rule 14).

Reason—This information unnecessary in the proper preparation of repair records.

Mr. Herbster: At this time I wish to call the attention of the members to brake beams applied generally by a good many railroads that would not pass A.R.A. test. The road I am connected with is removing a number of beams every day with small truss rods, undersized fulcrum; in fact, any and all kinds of material applied by other railroads, or by industries, and I believe we should impress upon the members of this association that they centralize their brake beam repairs so that the work can be properly done and meet with A.R.A. regulations.

The Chair: I concur with what Mr. Herbster has said, and if all present handle accordingly it would be very beneficial.

Rule 30

The committee recommends that Section (g) of this rule be modified as follows:

Proposed Form—When a car is *reweighed and* remarked the car owner must be *promptly* notified of the old and the new weights, with place and date. The proper officer to whom these reports should be made will be designated in "The Official Railway Equipment Register."

Reason—These reports should be furnished promptly.

Mr. O'Donnell: I wish to bring out the fact that a number of roads are simply re-weighing and re-stenciling cars in large numbers and they do not put on the A.R.A. standard size stencil. The idea is that we are obliged to give joint evidence and your loss is $3, or whatever you are getting for it.

B. F. Jamison (Southern): I might add that not only many railroads are re-stenciling cars in that manner, but many car owners are not using proper stencils. Some use one size figures and some another. I was in a shop lately where they were re-weighing cars and putting the lightweight on in 12-in. letters, that was the owner's standard and they had to go cut a stencil to meet the owner's standard. That, to me, is where standard marks would benefit, and I think some of us owners better take notice of this.

J. N. Brandon (M. St. P. & S. S. M.): A great many railroads have small capacity cars that have non-standard axles. I would like to ask what practice is used on other roads in re-stenciling these cars when they are re-weighed. Under new ruling, Rule 30, we have to re-stencil all cars with suitable capacity, etc. With a car 60,000-lb. capacity with non-standard axle we have nothing in the rule to cover it, and I would like to know what method is used on the different railroads for stenciling these cars.

Mr. Herbster: Isn't it given on Page 101 on 40,000 capacity cars?

Mr. Cheadle: I think that is the answer.

Rule 32

The committee recommends the addition of a new second paragraph to this rule, to read as follows:

"Steel tank heads (on tank cars) burst, except when due to inferior material, material less than required thickness, omission of reinforcing shoes where required, burned in flanging, welds or other improper workmanship; in any of such cases handling line must furnish car owner with statement showing actual condition of tank head which caused the failure."

Reason—To protect car owner against such damage unless failure occurs under any of above described conditions.

The committee recommends that Item 4 of Section (d) of this rule be changed as follows:

Proposed Form—No rider protection when necessary, if car is damaged to the extent shown in *Rule 44. The same responsibility applies also, if car is damaged to the same extent (per Rule 44), due to defective or inoperative hand brake rigging while handling car with rider protection, even though such faulty conditions may have developed during the switching operation.*

Reason—The elimination of Item 4 from Section (d), and the substitution of combination factors on certain classes of tank cars to constitute handling line responsibility, as proposed by the American Petroleum Institute, is not concurred in.

The committee recommends that Item 5 of Section (d) of this rule be modified as follows:

Proposed Form Coupling on with locomotive *when first car is damaged, including damage to adjoining cars (in consecutive order) in same draft.*

Reason—Reference to speed limit has been eliminated. The revision conforms to Interpretation No. 11.

The committee recommends the elimination of the last paragraph of this modified as follows:

Present Form—Defect cards shall not be required for any slight damage (new or old) that of itself does not require repairs before reloading of car. In no case shall defect card be required for raked or cornered sheathing, roof boards, fascia, bent or cornered end sills, if defects are old.

Reason—Covered by second paragraph of Rule 4.

Mr. Cheadle: It looks to me as though it is a big change in the rule. It used to be that if a car came over the hump with "rider protection" and damage occured it would be up to the car owner, but this new rule eliminates that. If you handle a car now with brake inoperative or defective the handling line is responsible.

Mr. O'Donnell: Why should not the man in charge of the car going over the hump be supposed to look over the car before it goes over the hump and see that nothing is wrong?

M. E. Fitzgerald (C. & E. I.): We have an arbitration decision between two Chicago lines, where the association has already recognized the fact that we must have effective hand brakes in going over he hump; we had the same protection all last year.

Mr. O'Donnell: May I put a question before you before we leave Rule 32: the change made by the Arbitration Committee "coupling on with locomotive when first car is damaged, including damage to adjoining cars (in consecutive order) in same draft." If the first car is damaged which is being coupled onto the locomotive and the second and third cars are all right and we have some damage after this, who is responsible?

Mr. Trapnell: My understanding is that if in coupling on with an engine you damage the first and second cars and the third car is O.K., but the fifth car is damaged, that the handling line would assume the damage on the first and second car, but on the fifth car the damage would be owner's responsibility, because it is not in consecutive order, providing there is no derailment.

W. P. Elliott (T. R. R. of St. L.): I would like to ask a question under Rule 32: that part relative to bursting out of tank heads. There is an exception there that when a head bursts, due to inferior material, material less than required thickness, omission of re-enforcing shoes, etc., the owners would be responsible, but the owners must be given a statement. Does the fact that you give the owners a statement change the responsibility, say, for a case of an end breaking out on a tank car due to not being properly reinforced? Why make the owners a statement if it is the owners' defect?

Mr. O'Donnell: I think the Arbitration Committee has done absolutely right in placing the responsibility in the hands of the owner. You cannot arbitrarily charge tank owners for $80 or $90 simply due to unfair usage. Give him the facts as required by the Arbitration Committee as stated "in consideration of the foregoing it would be unreasonable arbitrarily to hold the handling line responsible for defects of this character."

C. F. Straub (Reading): Before we get away from Rule 32, I would like to call attention to interpretation No. 2, which reads:

Q.—When flooring planks are cut out and can be seen from the outside of car, who is responsible?

A.—They are cardable defects where they can be seen in interchange from underneath the car.

A good many open top cars have patch boards put on them and owners do not repair them. Are they still cardable? Should not this association go on record as getting this interpretation re-written or eliminated entirely so that there will be an understanding that floor planks are only cardable when they are cut out new?

E. R. Campbell (Miss. Transfer): This is a case of defect card demanded by the owner and in checking them we find that cars are not repaired when they go home and come back again.

Mr. O'Donnell: The rule does not say that cars must be repaired when under load. If the card is taken off before the car is loaded, then they have to inspect the car.

Mr. Campbell: Nevertheless floor plank cut out is expressly mentioned as a defect and should be given necessary specific mention.

Mr. O'Donnell: Do not card unless repaired.

Mr. Fitzgerald: There is nothing in Rules 4 or 32 that provides he has to card the car owner for old floor planks cut out. Mr. O'Donnell says if he does make repairs he takes the card off and card issued is authority to bill car owners by the line that issued it. We get the car moving over our railroad and issue defect card for small defects as mentioned by this gentleman who just spoke. We card cars home to owners for repairs. We have no way of following that car up and making the owner comply with the provisions of the card, and I take it that if a card is issued for that floor plank the owner can bill as if he makes the repairs.

Mr. Straub: This is a case of car owners delivering their own cars with floor planks cut out, but patched over. We cannot always patch these when they are delivered to us, but when they go back empty it can be plainly seen, and also it can be seen that they are old defects, but a defect card can be demanded because the interpretation of Rule 32 says so. All that is necessary to clear this up is to try to get a new interpretation at this time.

F. H. Hanson (N. Y. C.): In regard to damaged tank heads, I would like to get the opinion of this association as to who is responsible. If the tank car owners must all comply with tank car specifications and put push pole pockets on the body of the tank or truck bolster, and if they place these push pole pockets on the tank head, naturally the yard or train crew who are doing the work will use the push pole pocket wherever it is located, and I think you will all agree that it will weaken the head. If we found a tank of that kind would we have the right to refuse it in interchange?

Mr. Fitzgerald: I do not know of any rule that will prohibit the interchange of that car if car is in continuous service. Rule 3 does designate certain such conditions and certain exceptions covering the interchange of tank cars, but it does not cover the general specifications and details of the car. From what I can see I do not feel that you could refuse the car, but I do feel that in the event of any distortion of head due to that push pole pocket being located on the sill of the tank it is an owners' responsibility, providing this damage is brought about by the proper use of this push pole pocket, but if the mark indicates that the switchman has applied the pole outside the push pole pocket, then it is unfair usage.

Mr. Hanson: That is the point I wanted brought out, to make it more clear to the rest of us. We recently had a tank equipped in that manner and the car was switched and struck twelve other cars standing on the track, no damage being done. Half an hour afterwards the car was found wrecked and in correspondence with the owner we called attention to the fact that the push pole pockets were riveted to the sills, and they came back and said that although they agreed that the push pole pockets were riveted to the sill of the tank they would not accept

a bill for the damage. The rule is so written that all you have to do is to make a statement of the conditions you just referred to, attach it to the billing repair card and bill the owners. Make another statement forwarding to the freight claim department and that will clear you of the responsibility.

Mr. Campbell: I would like to ask a question under Rule 32 that is not covered by the rule. That is the responsibility for damage in unloading gondola cars with the clam shell. All there is in the rule is in reference to unloading machines. This reads "material missing from cars due to handling by unloading machines." We have a great many cars in our country that are unloaded with a clam shell; they drop the clam shell in and raise the bucket from the floor, at such an angle that it breaks the side boards. Is this owners' defect or is it the handling line's responsibility?

Mr. Fitzgerald: As I interpret the rule we are supposed to go a little farther, in other words, I do not think the A.R.A. would embody in this little book of rules all the general detail of conditions under which you are supposed to use Rules 4 and 32 with reference to carding defects. They say that any damage to equipment brought about by unfair usage except under certain conditions is handling line responsibility. If you have a foreign car on your railroad and in unloading the car with a clam shell you break the car as the bucket raises or in any other manner, such as broken side stake, etc., it is a cardable defect and a handling line responsibility, the only protection you have is to repair the car at your expense and handle with the shipper through the transportation department to bring about better conditions at that plant. In a majority of cases if you talk with the shippers you can reduce the damage considerably, but it is a cardable defect.

Mr. Elliott: I consider that unloading a car with a clam shell in fair and ordinary handling will continue, and everybody is doing it. It is not cardable.

Mr. Cheadle: We do not consider a clam shell an unloading machine.

Mr. Herbster: In recent years we have contended that car construction must meet with the conditions under which it will be moved, and it is a fact that old equipment has been destroyed and owners are replacing the old equipment. I do not see why equipment cannot be put in condition to withstand ordinary handling. If the equipment does break up by reason of loading with a clam shell, I believe the owners ought to be responsible.

Mr. Cheadle: The rule says, "Material lost from cars due to handling on unloading machines." If you can get a claim charge on that I do not know how you do it. Rule 32 does not deal with the question of unloading, except in that paragraph.

Mr. Nelson: It seems to me that it would be very unfair to consider clam shell damage owners' responsibility. Some very expensive damage is done by clam shells on many of the modern cars. We have seen these hopper cars practically wrecked on the inside. I realize, however, that it is a very difficult matter to tell clam shell defect from other defects. There is no question but that many defects cards are issued today on assumed clam shell damage that should not be issued. But I agree that it is delivering line's responsibility and that it would be no more than fair to charge for all clam shell damage.

W. M. Allison (D. T. & I.): Recently we had this question up with one of our connections. We thought it a cardable defect in interchange. Meantime we wrote to Mr. Hawthorne of the Arbitration Committee and he advised that while it was not a cardable defect in interchange, it is up to the handling line where damage is done to protect car owner for such damage. Knowing we were more or less responsible for this damage, we gave card, and I believe this is in line with the Arbitration Committee's decision.

Secretary Sternberg: We in Chicago always feel that in cases of this kind we are fully taken care of by our Joint Inspection and we are satisfied.

Rule 91

The committee recommends that Section (c) of this rule be modified, a new paragraph be added as Section (d), and that present Sections (d) and (e) become new Sections (e) and (f) respectively, as follows:

Proposed Form—(c) No bills shall be returned for correction on account of other error or questionable charges unless the net amount involved is at least $1 and exceeds 10 per cent of the total amount of bill, but shall be passed for payment at once and the alleged error brought to the attention of the billing company within 60 days from date bill is passed for payment, but in no case exceeding six months after first receipt of bill. The billing road must furnish proper explanation or shall issue within 30 days countercharge authority on form shown on page 197.

(d) If objections to bill, as per Sections (b) and (c), do not amount to $1 in aggregate, no exception shall be taken, but bill shall be passed for payment as rendered. In any case, however, if entire bill is improperly rendered, it may be returned regardless of its amount.

Reason—To clarify the rule.

D. E. Bell (C. N.): There is a question I would like to have answered in connection with rendering bills. We have had at times some controversies on account of the similarity in car markings on several roads. It was our practice where the entire references were incorrect to render a bill, and I remember on some occasions that the other railroad companies objected to bills being rendered.

Mr. Jamison: I believe anyone from a billing office will bear me out in the statement that this particular rule is hard to live up to and by mutual consent the various railroads give and take on the proposition because 30 days is a short time in which to handle objections. That time goes by rapidly, particularly on railroads which have not adopted any progressive movement in their billing departments, such as centralization of billing. On the line with which I am connected, we have our own methods of centralization and all repair cards are prepared in the main office of the various divisions and we have been able to expedite greatly the handling by that method, and are trying as nearly as possible to live up to the letter of this rule. We have had very little trouble in handling that matter though, because the majority of the other railroads have to be lenient to others because they have to ask the same leniency for themselves.

Mr. Bell: Then no bill should be returned for correction, but should be passed for payment at once. We can correct car number or initials, but if entire bill is out of order, that is, if all the references are wrong, there is a question whether it would be handled under Section B or under Section D. In many cases the entire bill is improperly written. It has been the practice of the Canadian National to return bill if all the references were incorrect.

W. O. Watkins (H. V.): The Hocking Valley has much the same reference as the Lehigh Valley and we have never had them object to any card where the billing was wrong, nor do I believe any other road objects to the rendering of the bill.

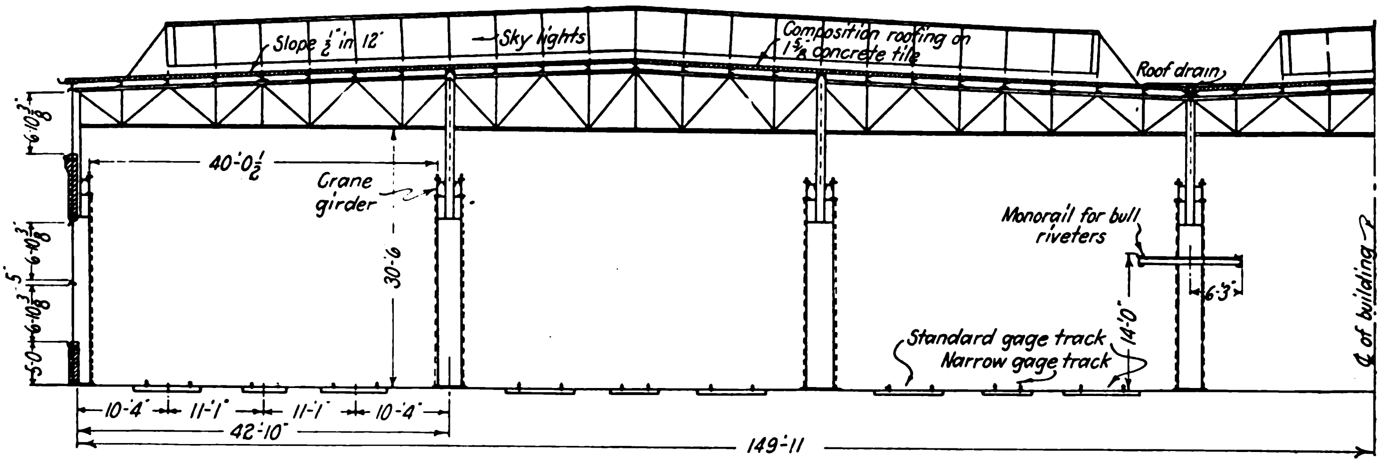
Steel underframe and trucks as received from the steel shop ready for application of wooden parts

E. J. & E. steel car shop at Joliet

Description of shop-method of organizing to rebuild twelve composite gondolas a day

FOLLOWING a fire in March, 1923, which entirely destroyed the steel car repair buildings of the Elgin, Joliet & Eastern at Joliet, Ill., this road erected a new steel car shop at Joliet featured by modern construction and equipment throughout, and with special provision for safe, sanitary and comfortable working conditions. This shop was designed primarily for the maintenance of various types of steel cars owned by the E. J. & E. but when it became necessary to re-build a series of heavy-duty drop-end composite gondolas as described in this article, arrangements were readily made, under the direction of J. Horrigan, superintendent of motive power, and C. H. Emerson, master car builder, to turn out twelve of these cars a day, the sills and other steel parts being fabricated in the steel shop and a station method developed on an outside track for handling the woodwork. Work in the steel shop was progressing on other all-steel cars simultaneously as they went through the various departments.

The new building is a brick and steel structure 300 ft. wide across the front and 500 ft. long on one side. Finding it impossible to extend the other side straight back owing to the cramped condition imposed by adjacent tracks, this wall is broken by two offsets which reduce the width of the building to 171 ft. across the extreme end. The building is 34 ft. high at the eaves. Six lines of steel columns extend lengthwise, as shown in the drawing, the columns in each line being 25 ft. apart and the lines spaced 42 ft. between centers. The effect of this arrangement is to divide the interior of the building into seven longitudinal bays with no partitions to obstruct the light or prevent ready communication throughout the floor area.



Cross-section through shop—Traveling crane and monorail runways indicated

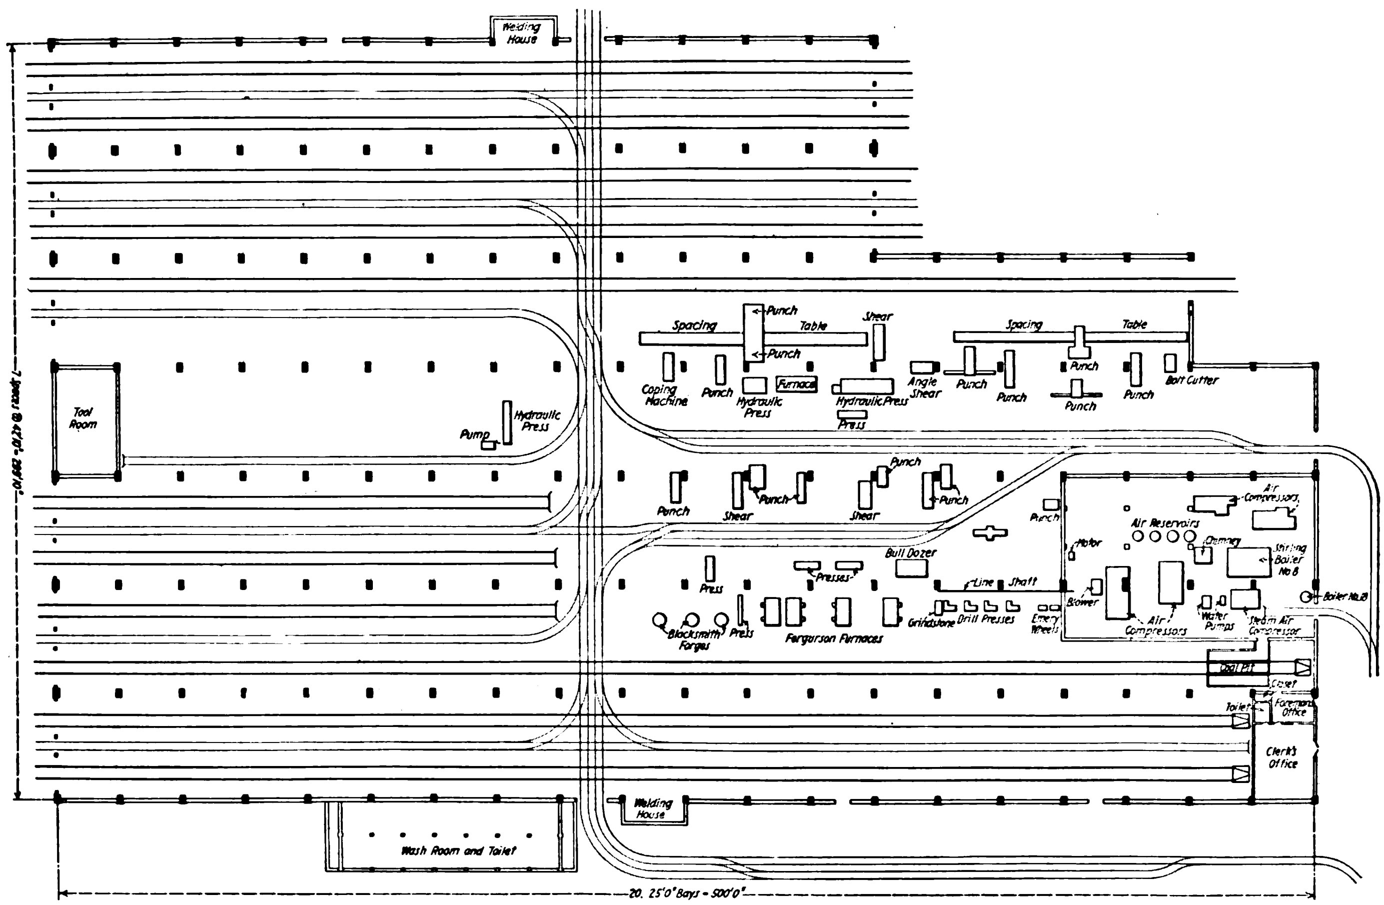
Ample light is afforded during the day by means of the large proportion of window area in the side walls and A-frame skylights which occur in three rows down the length of the building. The electric lighting system is also efficient, including 200-watt bracket lights on each side of each column, overhead lights of 300-watt in each bay, and numerous 60-watt drop lights. All wiring for

this lighting is carried in conduits and every light is equipped with a parabolic reflector.

Traveling cranes in all bays

The arrangement of these bays is such as to accommodate 11 standard gage tracks with a total capacity of 85 cars and seven narrow gage tracks. In the first two bays on the north side of the building, four tracks extend through the building to a ladder at the east end which permits ready connection with the switching and storage tracks in that vicinity. This arrangement also permits the repair of cars in successive stages which has been found to expedite production. The tracks are laid on 20-ft. centers which leaves room for a narrow gage track down the center of each bay between the standard gage tracks. Six-ton traveling cranes operate throughout the length of each bay on crane ways carried 25 ft. above the long. In the west half of the fifth and sixth bays are four standard gage tracks arranged with a narrow gage track in the center of each bay. The east half of the area, except for the boiler plant at the far end, is occupied by four oil furnaces, a number of forges and additional machinery, chiefly presses and punches. Each of the fifth and sixth bays, like the others, has two six-ton cranes. In addition, jib cranes are installed on a number of the columns to serve the big presses and punches in the vicinity. The seventh bay of the building is occupied throughout by two standard and one narrow gage track, except for the extreme east end where the shop office is located.

An important feature of the plant, aside from the large number of cranes, riveter runways and jib cranes, is the system of narrow gage track laid in the building. These tracks have already been described as extending between



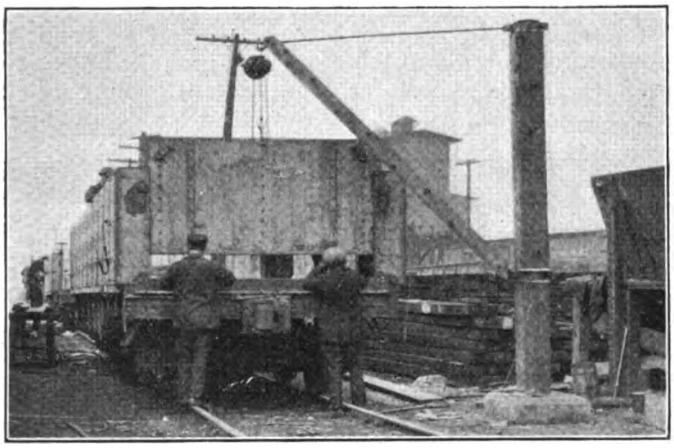
Drawing showing the location of the machine tools and track layout

top of the rail. Between the tracks at intervals of 40 ft. along the floor are two-way air cocks so arranged as to make it unnecessary to carry air hose across the track. The third and fourth bays are devoted chiefly to presses, shears, punches and other car repairing machinery, the location of which is shown in the drawing. Narrow gage tracks in this area serve a portion of the standard gage tracks and the machines. A toolroom is situated in the area in the forward end of the bays next to the west wall of the building. In addition to the six-ton crane the line of columns separating these bays carries runways for a collection of air-riveting machines. These runways are supported 6 ft. 3 in. from the columns on each side, 14 ft. above the floor, each serving five riveters, all of which are suspended from the runways by chain hoists.

The other three bays in the building are each 500 ft. all standard gage tracks and throughout the machine areas. Their main value, however, rises from the fact that they form an integral part of a system which extends all over the yards and also from the installation of two lines of this track crossing the building at the center with switches to all longitudinal tracks. This affords a connection between all tracks in the shop and facilitates communication with the areas outside the building. By means of an adequate number of electric tractors and trailers the economical handling of material throughout the plant is thus assured.

Special facilities have been provided for the workmen including principally a modern wash and locker room which is built adjacent to the south side of the building on the outside. This building is built 28 ft. wide and 100 ft. long. The first floor is equipped with individual

toilets and with washing facilities which include rows of double basins across the building in addition to basins along the wall, all of which are provided with spray faucets, while an upper floor is built for steel lockers and lunch room. There are 506 of these lockers, all installed on transverse tiers on concrete footings which serve also as seats. This building is well-lighted and ventilated and has concrete floors throughout. Two rows of drinking fountains extend through the main shop at intervals of about 120 ft. and three rows of urinals at

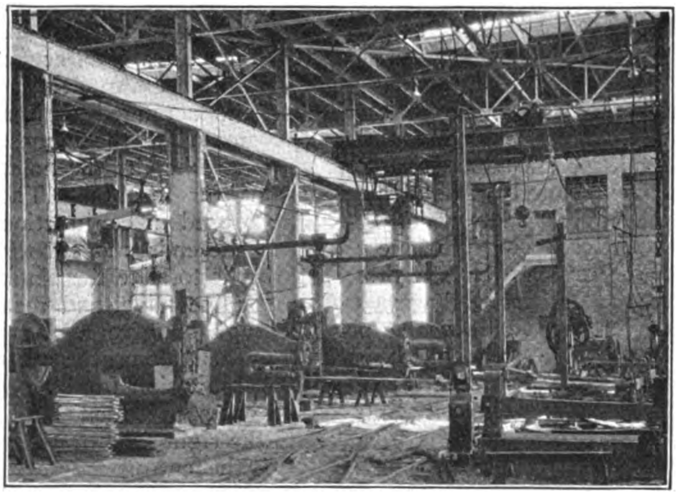


This jib crane located at a strategic point facilitates handling heavy end gates

intervals of 80 ft., the latter draining into sewer lines which also serve a collection of floor drains well distributed throughout the shop.

Another adjunct of the building is an offset 10 ft. wide and 30 ft. long added to the north and one to the south wall of the shop for electric welding work, it being the practice to move only the acetylene outfits from point to point in the shop.

No heating facilities are provided except for the office



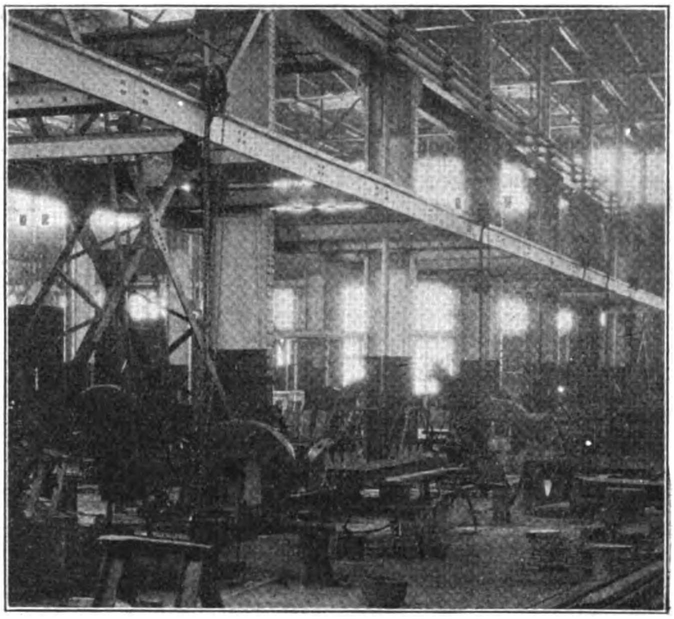
Car shop interior—View looking northeast, showing battery of punches

and for washing purposes. The boilers for this purpose, together with other power equipment, including four modern electrically-driven compound air compressors and heating boiler, are enclosed in a room in the east end of the building. This room includes an overhead platform for the electric transformers and is supplemented by a room provided above the office for repairing all electrical equipment. The machinery installed at this shop is shown in one of the drawings.

Organization for building composite gondolas

During 1924, 929 steel cars were given light repairs and 2,191 heavy repairs at the Joliet steel car shop. The men employed on this work averaged 514, the supervisory force consisting of one general foreman and nine foremen. When it became necessary to rebuild a series of 100,000 lb., drop-end, composite gondolas, arrangements were made to fabricate the new steel parts required on these cars in the steel shop and apply the decking, heavy wooden sides and reinforced end gates by the progressive system on an outside track adjacent to the steel car shop.

The location of the machinery in the steel shop is scientifically planned to provide straight movement of the long, heavy steel plates, channels, angles and other structural steel shapes through the shop with a minimum of handling and absence of back travel. The raw material comes into the third and fourth bays from the east end where it is cut to size, punched on automatic



View showing riveting yokes and runway

spacing machines and passed on to the west ends of the bays where portable pneumatic riveters, supported by chain hoists from monorails, are used by special gangs in performing the various assembling and riveting operations. The furnaces and hydraulic presses, shown in the drawing, are used for manufacturing the great quantity of pressed steel shapes used in the different types of steel cars.

In the composite gondolas under consideration, the steel work consists of built-up center, side and end sills, assembled, together with special reinforced end posts, to form a rugged steel frame for this car which must be strong enough to resist the severe service encountered in handling coal, steel billets, structural steel shapes and other heavy material from the mills. The organization for handling sill work consists of eight gangs, five gangs on center and side sills and three gangs on end sills. Each center and side sill gang, consisting of six car men, two car helpers, two rivet heaters and one car helper (supply), has a capacity to turn out nine center sills or ten side sills in an eight-hour day. Each end sill gang, consisting of three car men, one car helper and one rivet

heater, has a capacity of eight end sills in eight hours.

There are 24 assembling stations in the shop where 24 underframes are laid down. This work is divided into fitting frames and driving frames. The 12 frames which are laid down and fitted one day are driven and shipped the next. One fitting gang consists of five car men, and one driving gang consists of two car men, two car helpers and two rivet heaters. There are twelve of each of the above gangs required for the 24 stations which have an output of 12 finished underframes in eight hours.

When completed in the steel shop, the underframes with corner posts applied are loaded on flat cars and set on a track south of the shop. Here they are applied to trucks built up from new and reclaimed material which has been saved from the series of cars being rebuilt. The trucks and underframes then move to the track on which the wooden parts of the car are applied.

Station method used in applying wooden car parts

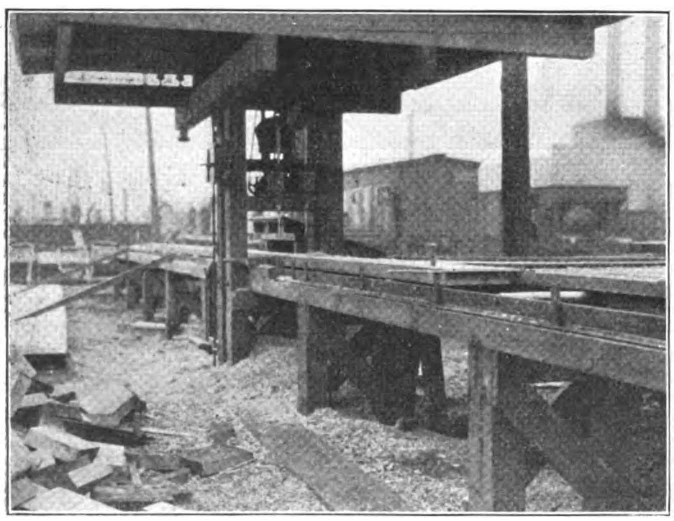
There are nine stations on a single track for the application of air brake equipment, deckings, sides, etc., and completing the car, two cars being worked on at the same time at each station. The gangs at each station are so organized and balanced that their work is completed at approximately the same time, and a move is made every 40 min., giving an output for the track of 12 cars a day.

At Station 1 the train line and air brake equipment are applied, two men working on the air cylinders and reservoirs and two other men applying the balance of this equipment. Stringers are also applied and nailed in place at this station by two gangs of four men each.

At Station 2 the riveting gang puts on all safety appliances, sill steps, grab irons, lift lever brackets and brake staff supports, the gang consisting of one car man, one helper and one rivet heater.

At Station 3 the couplers and side stakes are applied by a gang of eight car men.

At Station 4 the decking is applied by 12 car men.



Machine for boring holes in side plank and cutting them to length

At Station 5 the car sides are applied by one gang of eight car men.

At Station 6 the car sides are bolted in place by 16 car men.

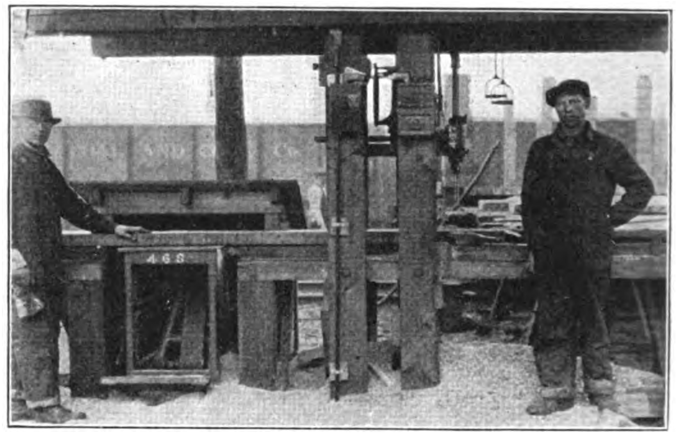
At Station 7 the end gates are made by six car men and applied by the same men who apply the car sides.

At Station 8 the decking is nailed by two men using pneumatic nailing machines.

At Station 9 the air brake is tested and the cars painted and stenciled.

The organization for handling the application of air brake equipment and wooden parts to these composite cars is notable for the smoothness with which it functions. Every effort is made to save unnecessary handling of material, and minimize the manual labor involved in that handling which is actually necessary. As a means to this end, woodworking machines, including cut-off saws, rip saws and boring machines, have been located as required at various points along the track with protection afforded against rainy and stormy weather.

For example, at Station 2 a special gang of five men handles and cuts off the 3-in. yellow pine decking; two men operate the rip saw for such pieces of decking as are not the right width; and two operate a boring machine,



Close-up view of machine for cutting off side planks

all of which are protected from the weather by means of a small shed. Several grooves must be cut the entire length of nine pieces of decking for each car to accommodate the nine tie rods which extend crosswise of the car. An ingenious arrangement, known as a "wabble" saw, enables this groove to be cut 1-in. wide by 7/8 in. deep, quickly and with only one pass over the machines.

The arrangement for machining and applying the 3-in. No. 1 Douglas fir side planks is exceptionally effective and clearly shown in two of the illustrations. An electric-driven, two-spindle boring machine is arranged with a table and rolls long enough to accommodate the longest plank and an automatic spacing device whereby the holes can be bored without measurement for location. The illustrations show a cut-off saw also used in conjunction with this boring machine to square the ends and cut the planks to length. The first operation is to slide the plank up the two inclined ways to the machine table, and then cut off one end of the plank enough to give a clean, square cut. The plank is then pushed along the rolls against a stop which gives the proper position for boring the first two holes. Subsequent holes are then bored rapidly as the plank is advanced to the right from position to position. At the final position, the cut-off saw cuts the plank to length, the plank then being slid on greased ways to a platform about three feet high between the machine and cars at Station 5.

An ingenious jib crane which assists in applying end gates is also shown in one of the illustrations. These gates are made by a gang of six men on a platform shown at the right in the illustration. The planks, cut to the right length, are shipped to this platform and the work consists of boring them with pneumatic drilling machines in accordance with holes in the steel sheets with which they are reinforced. The planks are then bolted in place and by means of the jib crane and differential chain

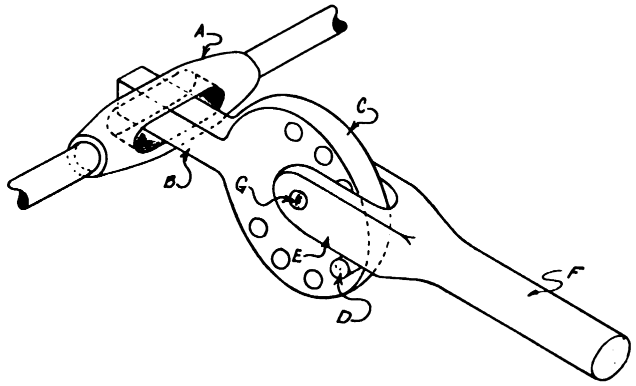
hoist illustrated, they are readily swung into place on the car. This gang of six men turns out 24 end gates in eight hours.

Aside from the new shop facilities at Joliet, careful attention to details in handling material and proper balancing of the gangs have been mostly responsible for the effective manner in which these E. J. & E. 100,000-lb. composite gondolas are being rebuilt.

Wrench for tightening turnbuckles

THE wrench shown in the drawing is used at the Waycross, Ga., shops of the Atlantic Coast Line for tightening turnbuckles on the truss rods of passenger cars, where equipment boxes, water tanks and other apparatus interfere with the free use of a straight bar.

The tongue, *B* is 1½ in. square and 7 in. long, forged in one piece with the 9-in. disc, *C*. The yoke *E* has sides ¾ in. by 3 in., with a depth of 6 in. The handle *F* is 1¾ in. in diameter and 10 in. long, forged in one piece



Wrench for tightening truss rods on passenger cars

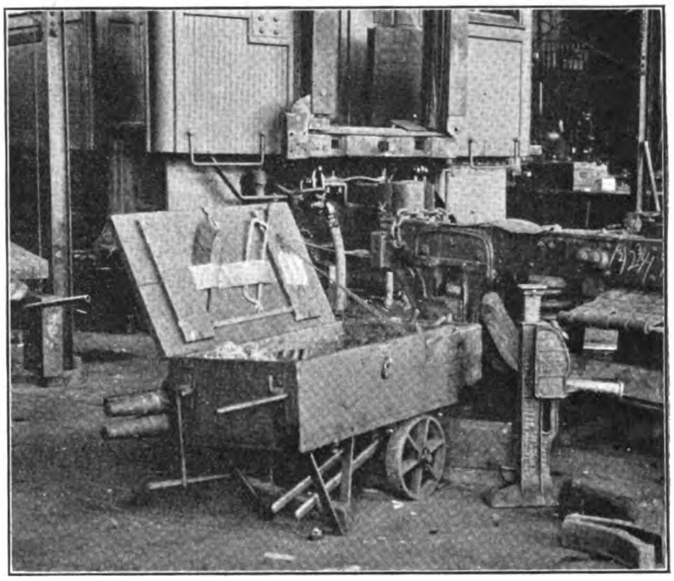
with the yoke. A piece of 2-in. pipe may be used for an extension to this handle when desired.

The disc is drilled at the center and fastened to the yoke with a 1-in. pin, *G*. Eight 1 1/16-in. holes are drilled in the disc as shown. A 1-in. pin, *D*, is inserted in a hole either above or below the yoke according to the direction the turnbuckle is to be turned. This provides a rigid wrench with the handle at a convenient angle so that a man may operate it to the best advantage. The description of this wrench was obtained through the courtesy of the Atlantic Coast Line News.

Car repairmen's portable tool box

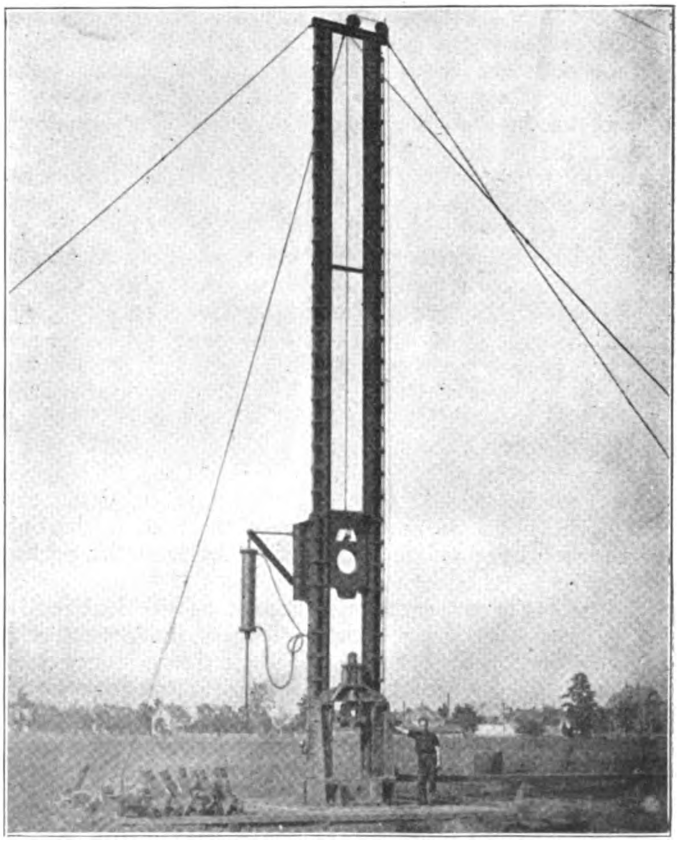
IN some car shops it is the practice for the workmen to keep their tools in a bench drawer or locker. This means that every morning the workmen have to get their tools out and carry them to the job and in the evening gather them up and put them away for the night. Thus, considerable time is lost before the men are ready to start work, to say nothing of tools becoming lost or stolen, owing to the fact that the tools are scattered all around the car on which they are working.

This condition is particularly true where the work is specialized and one gang goes all over the shop, i.e., a truck gang. The tool wagon shown in the illustration is used by a truck gang in a passenger car repair shop. The wagon is fully equipped to repair trucks. The main box contains the larger and most valuable tools. At the front end is attached a small box in which are kept drifts, chisels and other odds and ends used on the job. Two large wooden jack handles are carried on the side of the box in two leather straps. Beneath the box are carried large single end wrenches. Two Duff jacks are carried in the box. The handles of the wagon are so constructed that when they are not in use, they hang out of the way

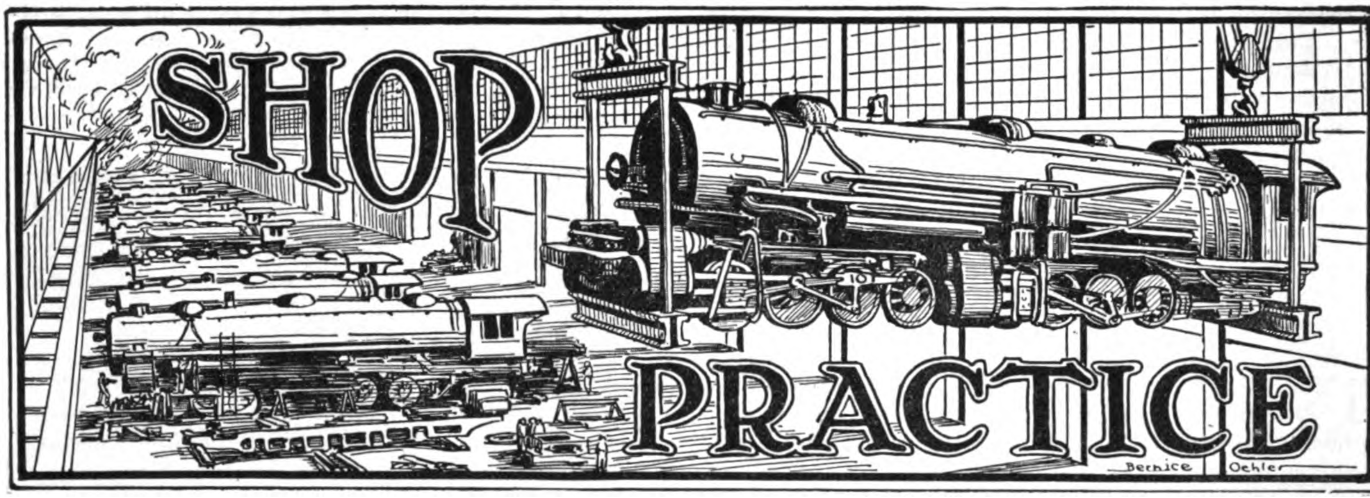


Portable tool box used by a car truck repair gang

perpendicular to the floor. At the end of the day, the tools can be quickly gathered up and placed in the box which is locked and left standing by the job until the next morning.



Drop test machine presented in 1900 to Purdue University by the Master Car Builders' Association



Inspection of flexible staybolts*

By E. S. Fitz Simmons
Sales Manager, Flannery Bolt Company, Pittsburgh, Pa.

THE development of the flexible staybolt, in this country, dates back to about 1890 and early experimentation was stimulated by the enormous number of breakages which occurred in the rigid type of staybolt. Probably the first type of flexible staybolt which could be readily inspected without removal was one of the round headed design, using a sleeve and removable cap, which was designed by John B. Tate of the Pennsylvania Railroad and introduced by the Flannery Bolt Company about 1904. This design gave promise of eliminating many of the weaknesses of former types and provided a means, though an expensive one, of ascertaining the condition of the bolt without removing it from the boiler. For these reasons it was quite generally tried out by many railroads and the results obtained were so satisfactory that its adoption and general use almost immediately followed.

In 1905 a Committee of the American Railway Asociation reporting on flexible staybolts said of it: "Though of comparatively recent date, it has been received with great favor, indicating the rapidity with which a new bolt of promising design is given a practical trial in the effort to cure the staybolt trouble." Further in this same report the committee stated the following: "A simple means of positively detecting cracked and broken bolts is an improvement needed by all flexible bolts that are in service at the present time. The removable of the cap, which will allow an examination of the bolt, is the only absolute means possible with flexible bolts of the present design."

In 1911 the act commonly known as the Locomotive Boiler Inspection Law became effective, under authority of which, rules requiring among other things the removal of caps from flexible staybolts for inspection purposes at special stated intervals, were promulgated and enforced.

The generally satisfactory service rendered and the very small percentage of breakage to total number in service (this type having become practically standard) created a doubt in the minds of many railroad mechanical officers of the justification of such a rule or requirement and it was quite generally, and for a time quite strenuously, opposed. However, the Locomotive Inspection Bureau, through its corps of inspectors, had indisputable evidence of the necessity for thorough and regular inspection, for while it was admitted that the percentage of breakage to the total number in service was small, it was shown beyond question of doubt that in certain instances breakage did occur to such an extent as to become a menace to life and property.

Investigations were begun to determine the cause of breakage in an endeavor to apply a remedy. A number of investigations confirmed the absolute necessity for careful and frequent inspections and also clearly demonstrated the need of a more accurate and positive method of test than the mere removal of the caps and an examination of the bolt heads.

Instances were found where, under bad water conditions, accumulations of scale between the body of the bolt and the inner wall of the sleeve were such as to solidly lock the bolt in the sleeve. The result was to render ineffectual the flexible feature and to cause the bolt to break at the fire box sheet.

During the past ten years, and more diligently during the past five years, after these abnormal conditions had been prominently developed, constant effort has been made to perfect a method of inspection that would provide greater safety and insure against loss of life, injury to persons, and damage to property.

The first actual service test of such a method was made in August 1920 on large Mallet type locomotives where abnormal conditions existed and where breakage of flexible bolts was excessive. This method consisted of the installation of flexible bolts with telltale holes extending from the firebox end entirely through the body section and terminating within the bolt head, and the testing of these bolts at regular intervals with a specially constructed instrument to determine definitely that the telltale holes were open and, therefore, operative throughout their entire length. This was accomplished by so constructing the instrument that an electrical circuit would be established when contact was made at the end of telltale hole.

During this service test, two distinct features were developed:

*Abstract of a paper presented at a meeting of the Southern Railway Club, Atlanta, Ga., September 17, 1925.

First—that moisture, due to temperature changes, condensed in the telltale hole and formed rust or iron oxide which gradually increased to such an extent as to interfere with the insertion of the testing instrument. In seeking a remedy for this condition, various methods were tried, the most satisfactory and the one at present in use being the electro-plating of the walls of the telltale hole with copper. Four years experimental work and service tests have demonstrated the complete success of eliminating the difficulty by this method.

Second—that cinder and other foreign matter accumulated in the telltale holes to such an extent as to require excessive labor to dislodge and remove it in order to permit the insertion of the testing instrument. The cost and time required for this made the method impractical. After numerous experiments it was found that a closure of fire-proof porous material applied in the end of the telltal hole prevented the accumulation and at the same time permitted leakage of steam or water in case of fracture, and that it was also readily and cheaply removable to allow insertion of the testing instrument.

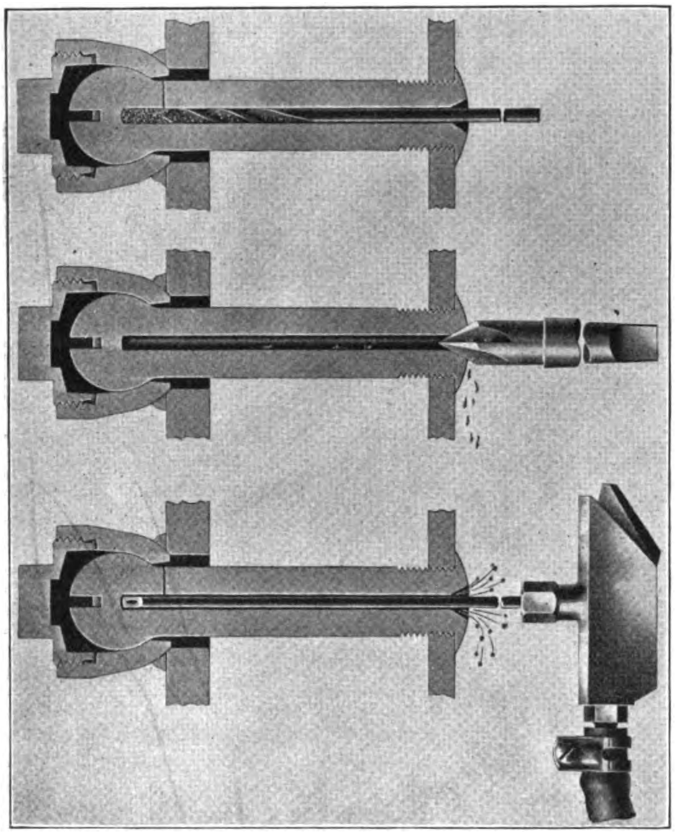


Fig. 1—Cleaning out the telltale hole by means of special air tool

Application of telltale flexible staybolts

The telltale flexible bolt is identically the same as the Tate bolt with the addition of a telltale hole extending through the entire length of the body section and terminating within the head of the bolt. The walls of the telltale hole are copper plated to prevent rust or corrosion within the hole and to prevent them from becoming closed from this cause.

They are applied exactly the same as the ordinary flexible bolt. If the method of riveting closes the end of the hole, it may easily and quickly be re-opened, after which a porous fireproof closure is applied that will prevent the accumulation of foreign matter from entering the telltale hole and that will permit leakage of steam or water in case of a break or fracture, which serves as a daily indicator of the condition of the bolt.

Inspection of telltale flexible staybolts

In addition to depending on the leakage through the telltale hole, an inexpensive method of periodically checking up the condition of the telltale hole is provided as follows:

The fireproof porous closure is first removed, after which the specially constructed testing instrument is inserted. Upon reaching the extreme end of the telltale hole and making contact therewith, a light flashes in the handle of the tester indicating that the hole is open and therefore operative throughout its entire length.

The method of testing has been built upon the fact that a broken bolt having a telltale hole will show leakage of water or steam, providing the telltale hole is open and operative and that it extends to every breakable part of the bolt.

The tester is so designed and constructed that it will positively indicate whether or not the telltale holes are open throughout their entire length. After inserting the tester in each telltale hole and securing light in the handle (which indicates that contact has been made with the extreme inner end of the hole) if the bolt is broken, or fractured into the hole, leakage will positively occur when water pressure is applied to the boiler.

Use of the tester

First, with a sharp pointed pin or punch and a light hammer, break through the porous closure; then blow all of the remaining particles out of the telltale hole with the air tool—shown in Fig. 1. Attach the ground connection in any convenient telltale hole, then insert the tester rod into each telltale hole until contact with the end of each hole is secured. Such contact is indicated by the lighting of the bulb in the tester handle, as shown in Fig. 2. After contact has been secured in every bolt, apply water pressure to the boiler and every defective bolt will be indicated by leakage through the telltale hole. If no defective bolts are found, or after replacing any that are found, again close the telltale hole with the fireproof porous material and the locomotive is ready for service.

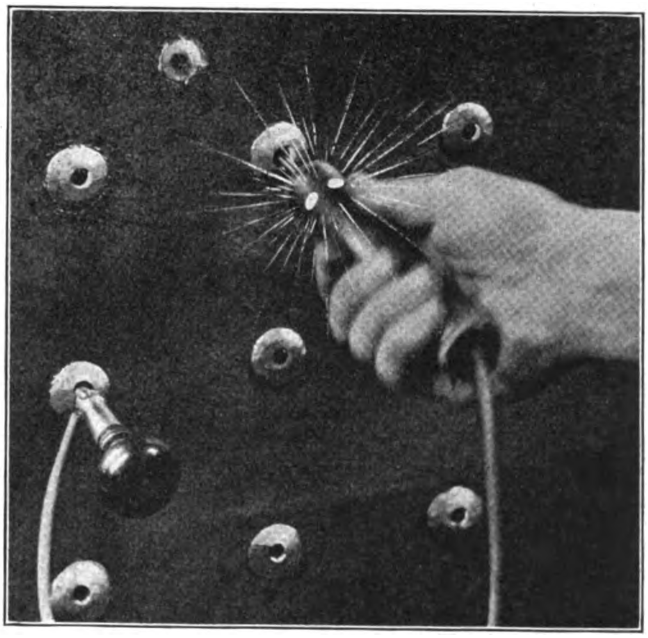

Fig. 2—A light in the tester handle indicates that the telltale hole is open the full length

Cases may occur where breakage or fracture will be

indicated by leakage and will not be observed or detected at the time they develop, as for instance bolts in locomotives in pusher service at isolated points or bolts located behind brick arches, grate bars, etc, and in which the telltale hole will gradually become filled by accumulation of scale from the boiler water. Therefore, whenever the tester is inserted, it strikes an obstruction and fails to show a light in the handle, as is shown in Fig. 3. In such cases the tester should be removed and a special cleaning drill applied to remove the obstruction. After drilling, blow clean with the air tool such as was shown in Fig. 1, re-insert the tester, and if the hole has been thoroughly cleaned, contact will be secured and indicated by the lighting of the bulb as before described and when water pressure is applied, leakage will occur.

Bear in mind that securing contact in the telltale hole does not indicate that the bolt is in good condition, but only that the telltale hole is open and operative throughout its entire length. It is the failure of the bolt to leak under pressure after contact has been obtained which indicates that it is not broken.

The present method of inspection requires from three to four or more days, the principal part of the work being the removal and replacement of parts, rather than the actual time required by the inspector to examine the bolts.

By the new method herein described, it is not necessary to touch or remove anything on the outside of the boiler and the entire test on a modern locomotive boiler containing a full installation of flexible bolts can be completed within an eight-hour day—and at a labor cost of from $10 to $20, depending on the size of each respective installation.

The cost to strip, remove caps, inspect, and replace runs

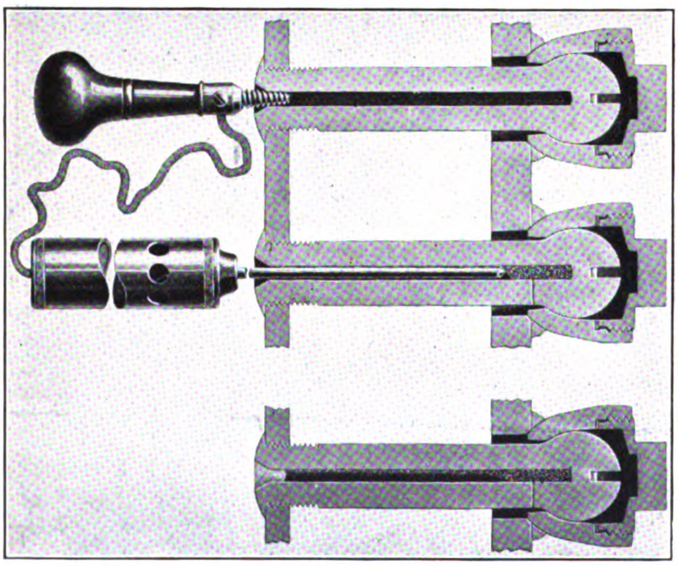

Fig. 3—An obstruction in the telltale hole prevents the tester rod from making contact. This condition is indicated by the failure of test lamp to light

from $100 to $250, depending upon the size of the locomotive and upon the facilities at hand, and in addition, results in two, three, and sometimes more, days loss of engine service.

The principal advantages of the new method of inspection are: Greater safety by constant daily indication of bolt conditions; material reduction in maintenance costs by reason of eliminating a vast amount of labor now required under the older method of inspection, and a substantial saving in locomotive service by reason of being able to make inspection by the new method at the time of the regular annual hydrostatic test and without additional loss of locomotive service.

A number of railroads have been using the new method of inspection just described for some time, irrespective of the fact that the Government had not yet approved it, because they were convinced that it added such an immeasurably increased factor of safety that it would more than compensate for the additional cost of this method of testing in addition to complying with the Interstate Commerce Commission rules that require the removal of caps every two years. The Locomotion Inspection Bureau, however, has been fully aware of the use of this new method for the last four or five years, has been checking

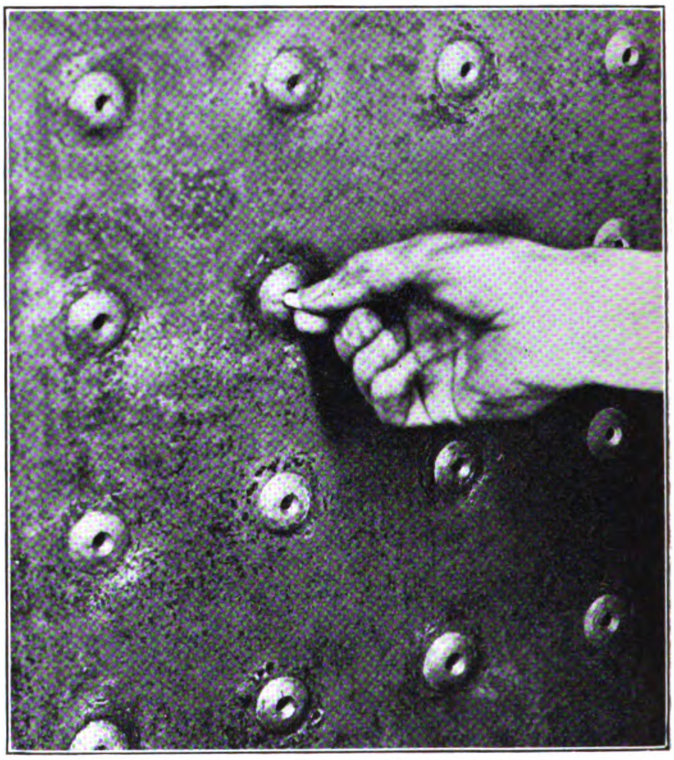

Fig. 4—Applying the porous closure to telltale hole after inspection

up the results carefully, and when a number of the railroads that have been using this method of inspection for some time made an application for a modification of Rule 23, careful consideration was given with the result that, at a general session of the Interstate Commerce Commission held at its office in Washington on July 26, 1925, it was ordered that Rule 23, as approved in the order of the Commission entered April 7, 1919, be, and the same is hereby amended to read as follows:

23. *Method of testing flexible staybolts with caps.*

Except as provided in paragraph (b), all staybolts having caps over the outer ends shall have the caps removed at least once every two years and the bolts and sleeves examined for breakage. Each time the hydrostatic test is applied, the hammer test required by rules 21 and 22 shall be made while the boiler is under hydrostatic pressure not less than the allowed working pressure.

(b) When all flexible staybolts with which any boiler is equipped are provided with a telltale hole not less than 3/16 in. nor more than 7/32 in. in diameter, extending the entire length of the bolt and into the head not less than one-third of its diameter and these holes are protected from becoming closed by rust and corrosion by copper plating or other approved method, and are opened and tested, each time the hydrostatic test is applied, with an electrical or other instrument approved by the Bureau of Locomotive Inspection, that will positively indicate when the telltale holes are open their entire length, the caps will not be required to be removed. When this test is completed, the hydrostatic test must be applied and all staybolts removed which show leakage through the telltale holes.

The inner ends of the telltale holes must be kept closed with a fireproof porous material that will exclude foreign matter and permit leakage of steam or water, if the bolt is broken or fractured, into the telltale hole. When this test is completed, the ends of the telltale holes shall be closed with material of different color than that removed and a record kept of colors used.

(c) The removal of flexible staybolt caps and other tests shall be reported on the report of inspection Form No. 3, and a proper record kept in the office of the railroad company of the inspections and tests made.

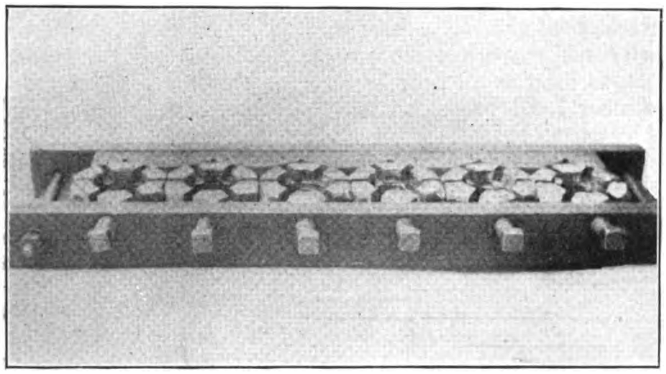
(d) Fire box sheets must be carefully examined at least once every month for mud burn, bulging, and broken staybolts.

(e) Staybolt caps shall be removed or any of the above tests made whenever the United States inspector or the railroad company's inspector considers it desirable in order to thoroughly determine the condition of staybolts or staybolt sleeves.

Effective shop jigs and devices

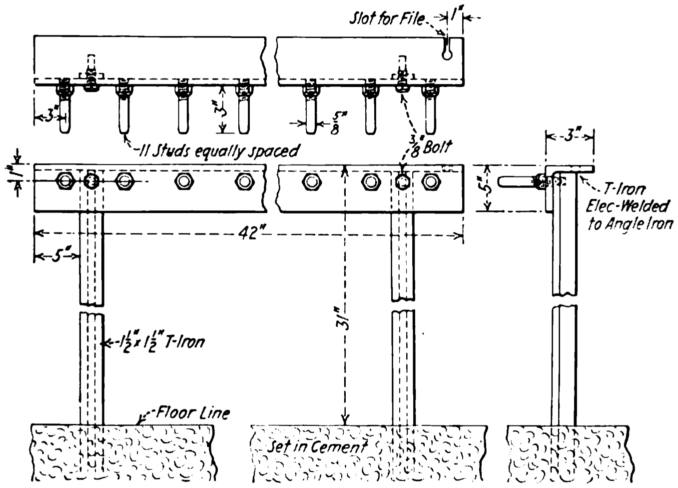
American Railway Tool Foremen's committee report on the subject calls attention to many shop devices of value

One of the features of the American Railway Tool Foremen's convention, held at Chicago, September 2 to 4, was the report on jigs and devices for locomotive and car shops, read by Chairman Henry Otto,



Jig used in cutting slots for castle nuts

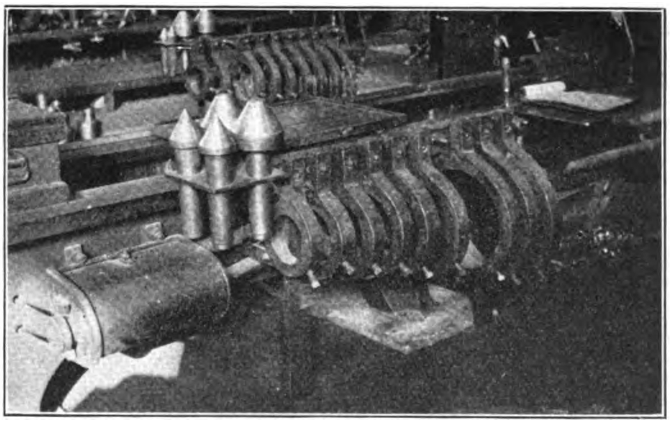
tool foreman of the Atchison, Topeka & Santa Fe at Topeka, Kan. An imposing aggregation of photographs and blue prints of labor-saving shop devices were dis-



Rack for holding lathe dogs or drivers at crank pin and axle lathe

tributed for the examination of members of the association and posted around the walls of the convention hall. Some of these have already been described in previous issues of the *Railway Mechanical Engineer* and a selected list of eight others are illustrated in the following article. As mentioned on the floor of the convention the committee expressed its appreciation for help in collecting data and photographs of many of the shop kinks to J. R. Phelps, shop apprentice instructor of the Atchison, Topeka & Santa Fe at San Bernardino, Cal.

Cutting slots in castle nuts—The illustration shows a device for cutting slots in castle nuts of sizes that are not carried in regular stock. The device is easily made of a scrap driving box shoe in which a strip is placed on one side, machined to fit the corners of six or more nuts and provided with a corresponding number of set screws on the other side to hold the nuts tightly in the jig while slots



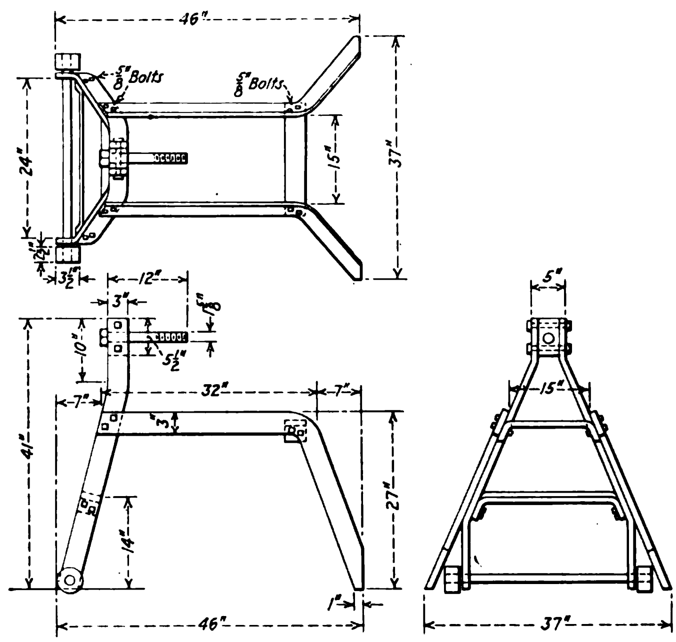
Rack for lathe dogs and centers

are being cut. The set screws are pointed downward at an angle of 5 deg. to offset any tendency of the nuts to work up under the action of the milling cutter. By having the machine operator turn the nuts as fast as they pass under the cutter, when one complete cut has been finished everything is in readiness for the next cut and there is no lost time in setting up. It will be noted that the sides of the shoe are tied together by two ⅝-in. bolts to give the jig added rigidity and prevent either side of the shoe breaking off, as might happen particularly if made of cast iron.

Rack for holding lathe dogs—Two racks for holding lathe dogs and lathe centers are illustrated. It will be readily seen that by the use of these racks the lathe dogs or drivers are kept off the floor and out of the way, at the same time being within convenient reach of the lathe operator when needed. There is less liability of the dogs being lost or damaged and, moreover, this arrangement favors the sweeper who does not have to move them about

from one place to another in attempting to sweep the floor.

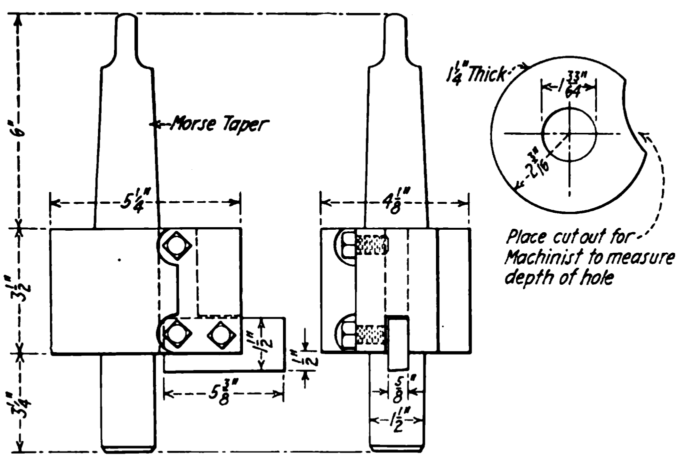
These racks are also used for holding lathe centers. One of the most important things about a lathe is its centers and by keeping the extra centers out in plain view, as illustrated, they are not so likely to be damaged as would be the case if thrown in a drawer with other tools or possibly left on the floor. Moreover, the machinist or foreman can at all times see the condition of the lathe



Rack for holding back chamber head while being worked on

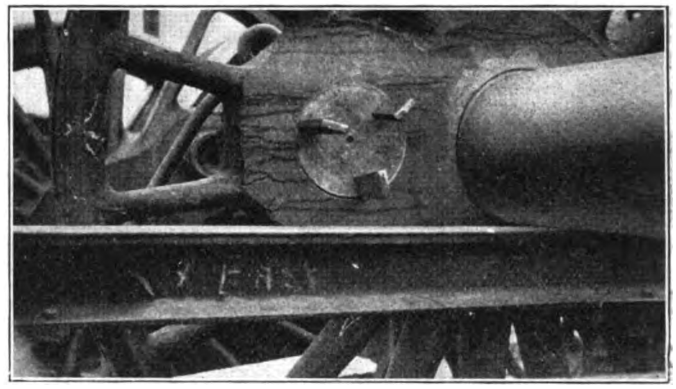
centers and this arrangement eliminates any possibility of the last extra lathe center being damaged and causing delay to an important job while it is being annealed and re-trued.

Valve chamber head rack—The back valve chamber head with its integral guides for the valve crosshead is a



Tool for facing the stuffing box of back valve chamber heads

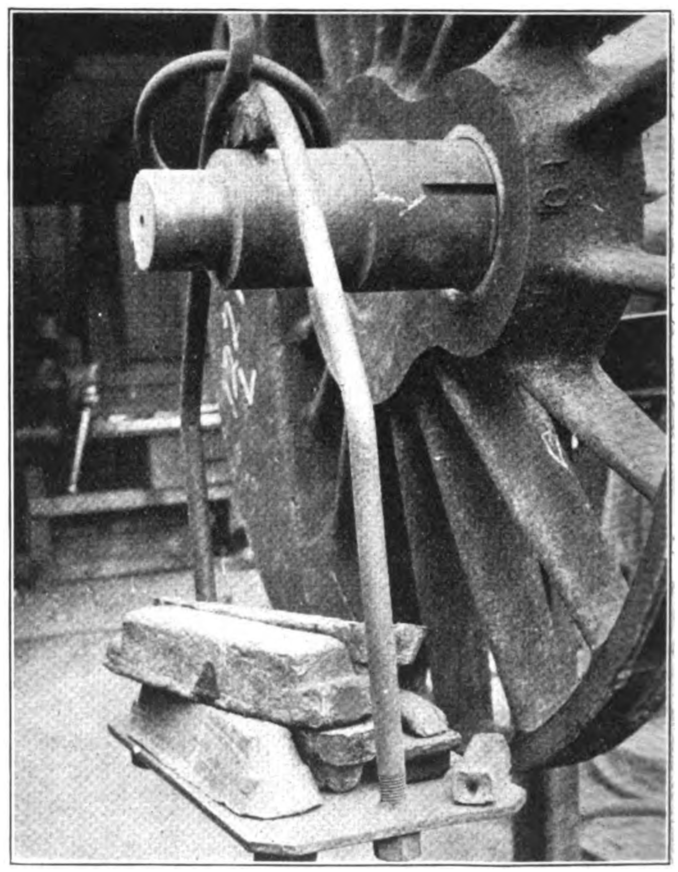
complicated casting of considerable weight which is extremely awkward to handle at the bench. A simple but convenient rack for holding any size of back valve chamber head while being worked on, is illustrated. This rack consists of a built-up framework of 1-in. by 3-in. bar iron bolted together and supporting at the top a horizontal holding bolt, 1⅝ in. by 10 in., to be inserted in the stuffing box hole in the valve chamber head. By means of suitable washers and a nut the head can be drawn up against the framework and held firmly at any angle required for the most convenient performance of the particular job at hand. The distance of the horizontal holding bolt above the floor is such as to bring the back head at approximately bench height. It will be noted that two legs of the rack are provided with small wheels so that by



Three taper keys hold temporary crank pin in place

lifting the other two legs one man can readily move the rack across the shop floor and yet it will not move too easily while work is in progress on the valve chamber head as long as all four legs are on the floor. Back valve chamber head work can be performed better, easier, and in less time by the use of this rack.

Facing stuffing box holes—A tool for facing the stuf-

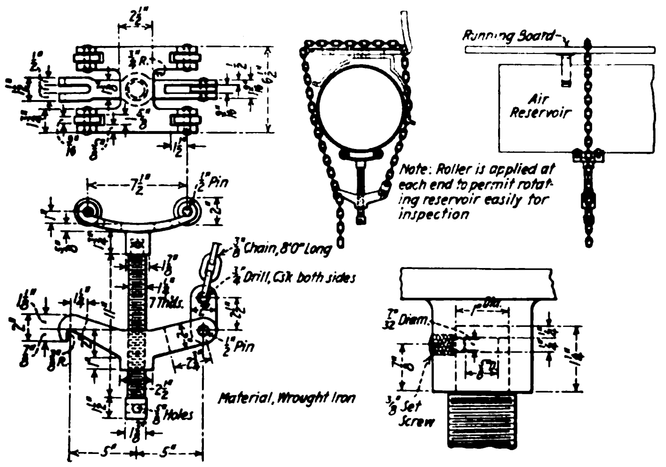


Temporary crank pin for use in quartering driving wheels

fing box holes in back valve chamber heads is shown in one of the drawings. Formerly this job had to be done on a horizontal boring bar often over-crowded with other work. With the tools shown, the facing operation can be performed complete on any heavy duty drill press, the

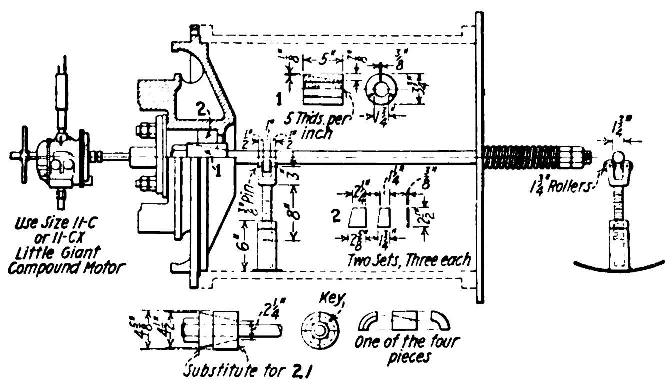
drilling, boring and facing operations all being done at one set-up of the back valve chamber head. The amount of metal to be removed and the width of the cut make it necessary that the pilot of the tool be guided by the block shown. The pilot is turned to 4⅜ in. in diameter so that it just fits in the bore of the stuffing box. The segment cut out is to enable the machinist to measure to the bottom of the hole and face off the stuffing box enough to secure the proper depth.

Temporary crank pins—A good start is often gained in fitting up a pair of new main driving wheels if the wheels can be weighed and counterbalanced and this work fin-



Rollers for testing main air reservoirs on locomotives

ished before the crank pins are made and pressed in. The illustrations show an arrangement whereby temporary crank pins with crank arms (if any) can be quickly applied and used in counterbalancing. Three tapered keyways are milled or planed in each of a pair of scrap crank pins taken from the same class of locomotive as the one for which the new wheels are being made. These keyways are ⅝ in. wide and take tapered keys 19/32 in. thick by 9 in. long and having a taper corresponding to



Cylinder head supporter

that in the crank pin. A taper of 1⅛ in. in 12-in. has been found to give good results.

The temporary crank pins are an advantage in practice when a pair of driving wheels is due to be weighed and for some reason the main pins are not ready; or possibly the tires must be put on and then after the crank pins are finally applied and the wheels put on the weighing rack with the proper weights hung on the pins, it develops that the tires must be taken off again to get the necessary lead into or out of the counterweight pocket. This is very likely to happen on an engine that has not been previously weighed and brought up to standard. With the temporary crank pin arrangement the wheels can be weighed and the tires put on to stay, whether the main crank pins are ready or not. Key-ways should be cut in two old scrap pins for each class of engine on which much weighing is done. The eccentric crank should be in position when the weighing is done; it being left off in the illustration in order to give a clearer picture.

Main reservoir rollers—A convenient arrangement for use when testing main air reservoirs on locomotives is shown in one of the drawings. The particular advantage of this device is that it enables the reservoir to be thoroughly tested without taking it down from the locomotive. The principle of operation is evident from the drawing, a chain and bracket with four rollers, rolls simply being applied around the running board and under each end of the reservoir. All pipe connections are broken and the reservoir clamps loosened. By tightening the screw underneath the rollers the weight of the reservoir is taken off the clamps and is supported on the rollers. The reservoir can then be revolved slowly for the hammer test with the assurance that every part of it will be thoroughly examined and tested.

Cylinder head supporter—The necessity of grinding back cylinder heads to a joint on the cylinders is generally admitted and as these heads carry the guide blocks and are heavy, the supporter shown in the illustration will be found useful in taking the weight off the cylinder counterbore and permitting the cylinder head to turn more easily. The supporter consists simply of a pair of 1¾-in. rollers set one at each end of a forked rod threaded into a sleeve and provided with a lock nut. The tension of the cylinder head against the cylinder is adjusted by means of the spiral spring and nut on the end of the center rod. A compound pneumatic motor is used to revolve the cylinder head during the grinding operation.

Drawbars and pins*

By James T. McSweeney,
Master blacksmith, Baltimore & Ohio, Garrett, Ind.

ON the Baltimore & Ohio drawbars and pins are made of steel billets or rolled steel bar at a workable heat. The holes are drilled in the ends. By this method we get a better bearing on the pins. If there is to be an oblong hole in the drawbar ends, such holes are slotted and not cut out with torch. The purpose of having an oblong hole in the drawbar is to relieve the shock on the pin when coupling on to a train.

No holes in the drawbars are required. When the holes are found to be worn to ¼ in. diameter larger than the original size, the bar is scrapped and the material is used for some other purpose. Drawbars and pins are removed and carefully examined every three months for possible defects. When the locomotives are undergoing classified repairs, the drawbars are removed and heated to a cherry red, given a thorough examination for defects while hot and are then allowed to cool slowly in a dry place, free from dampness or drafts. The welding of drawbars either in the blacksmith shop or by the autogenous method is not permitted.

Drawbar pins are made from rolled steel bar stock and used without turning. In my experience I find that pins made from bar stock and not turned, give the best wear. If the pins are turned, they should be annealed before being placed in service. This makes the pin tougher and it will withstand wear longer.

*Abstract of paper presented at the twenty-ninth annual convention of the International Railroad Master Blacksmith's Association, Cleveland, Ohio, August 18-20, 1925.

The importance of the toolroom to the railroads*

Some ways in which it can be operated to help reduce shop and enginehouse costs

By E. L. Woodward
Western Editor, Railway Mechanical Engineer

The importance and necessity of an efficiently organized toolroom in any railroad shop or enginehouse where a real attempt is being made to cut costs is self evident. The toolroom began to be an important factor in transportation with the first locomotive which was built. It is said that in 1829, before going ahead with his plans for the construction of the Rocket, George Stephenson was compelled to make a small, hand-operated engine lathe with which to fashion some of the locomotive parts. Presumably he also made the tools used in connection with the engine lathe and therefore fulfilled all three functions of locomotive designer, builder, and toolmaker. Since 1829 the toolroom has developed and now plays its full part as one of the vital departments of every railroad shop and enginehouse of consequence in the country. It may well be likened to the heart of the locomotive or car repair shop for from it flow the tools without which no other shop department can operate efficiently.

The motto of the American Railway Tool Foremen's Association, "For Greater Efficiency in the Railway Tool Service," is most happily selected, particularly the word service. It is not only the function of the tool foreman and his organization to provide necessary tools required for the various operations in repairing cars and locomotives, but it is doubly important that these tools be provided *when* needed, *where* needed, and in good working condition. In other words, the main object of the toolroom should be to provide real tool service to help eliminate as far as possible every lost moment, unnecessary step, and ineffective movement of the mechanics, repair men, helpers, and other employees in railroad shops and enginehouses.

There never was a time when this improved quality of tool service was more needed than at present. In June, 1925, 518,003 men were employed on maintenance of equipment work and receiving a compensation of $66,-228,792. The money which can be saved or wasted depending upon the kind of tools furnished these men can be readily appreciated. This is the opportunity, as well as the responsibility, of railway tool foremen.

There are many essentials to the provision of adequate tool service but these can probably almost all be summed up under one of the three heads (1) effective personnel organization, (2) up-to-date methods of handling the work and (3) toolroom equipment to meet modern needs.

System tool organization needed

As in all shop departments, the most important problem connected with toolrooms is one of supervision. Unquestionably those roads which have created the position of general supervisor of tools, and appointed a competent tool foreman to perform the duties of this position for the entire system have found the investment profitable. A railroad makes or saves money as a unit. Locomotives and cars are standardized for the system as are also shop practices to a considerable extent. Railway tools and toolroom practices must also be standardized for the system, for maximum economy, and practically the only way the managements can be sure of accomplishing this is by appointing an experienced man to devote his whole time to the work of general supervision. If some roads are too small to warrant the appointment of a general supervisor of tools some method must be devolved of co-ordinating the ideas of the respective tool foremen at individual points, otherwise there will be as many different types of special and commercial tools ordered and used as there are foremen. Some of these tools will be less efficient than others and an excessive number of repair parts must be carried in stock to keep them in operation.

Next to a general tool supervisor who can develop system standards of railway tools and toolroom methods, experienced local foremen and toolroom employees are required, for upon the accuracy and skill of their work depends in large measure the efficiency of the shop or enginehouse at which they are located. It is hardly necessary to point out to the members of this association the advisability of attracting to the toolroom as capable men as possible, training and developing them, and making their working conditions as attractive as possible in order that they may stay on the job and not necessitate the frequent breaking in of new men. The question of wages and general working conditions is not for the tool foreman to decide but it is in his power to make his men like their jobs or, on the other hand, begrudge every hour they have to spend in the toolroom.

The tool foreman has a wonderful opportunity to increase the efficiency of tool service by studying his men, taking a tactful interest in their personal problems, and in common with all other railway supervisory officers combating the campaign of criticism against the railroads and the tendency (probably less common now than it was three years ago) of doing as little work as possible for a day's pay. It may not always be easy for a foreman to meet the arguments of a glib-tongued fellow who spreads insidious propaganda with little regard for the truth. It is up to the foreman, however, to look up the facts and refute the man's arguments, otherwise he will lose standing with his own men and be negligent in duty to the railroad which employs him and on whose success and prosperity his own livelihood depends.

The tool foreman should help his men increase their knowledge of tools and tool making and in particular lend encouragement and assistance to any apprentice boys who may show special aptitude for tool room work. In connection with educational work the tool foreman should not neglect the opportunity to attend conventions like the present one of the American Railway Tool Foremen's Association. He should begin his campaign for permis-

*Address before American Railway Tool Foremen's Association at Chicago, September 4, 1925.

sion to attend these conventions early enough in the preceding year to insure success and wherever possible bring one or two or more of his leading workmen with him. They will all be benefited in direct proportion as they help in the preparation of papers, participate in discussion and above all take home and put into practice some of the ideas here developed. The advisability of reading all possible books and literature on tool making subjects need hardly be emphasized and the next best thing to attending the conventions is to read the record of the proceedings published in the *Railway Mechanical Engineer* and other technical papers which report the meetings.

Method of organizing the work

Space and time limitations prevent more than a mere outline in this paper of toolroom methods which have proved effective on various roads. As may be inferred from previous paragraphs, one of the greatest possibilities of economy on a railroad system as a whole is by the adoption of standard tools best suited to the needs of the individual roads. These tools should be limited to as few kinds and sizes as consistent, in order to minimize the number of repair parts which must be carried in stock and reduce the possibility of delay due to specific repair parts not being in stock. Standard instructions covering the kind of commercial tools to be ordered and the methods recommended for making those of special design in railroad toolrooms, have been compiled in the form of tool folios by several roads and promise to be real cost reducers through reduction of initial tool cost, cost of tool maintenance and by providing more efficient tools to the various shop departments.

Standardization is the keynote of economy in the toolroom. With system standardization, many of the special tools which railroads must make for themselves are used in such quantities as to justify the organization of a central manufacturing tool department, equipped with modern machines to turn out those tools at greatly reduced cost. The saving in cost of making the tools, however, is insignificant compared to the reduced cost of performing shop and enginehouse work with tools which are properly designed, made of the right kind of material and turned out with the proper inspection and supervision over each operation.

The question of how large a road must be to make a centralized manufacturing toolroom profitable is not easy to decide. Doubtless there should be many more toolrooms of this type than now exist.

What toolroom equipment is required

An able discussion of the types of machines needed in the large manufacturing toolroom, medium size maintenance toolroom and smaller toolrooms at outlying points has been presented at this convention by C. A. Shaffer, supervisor of shop machinery and tools of the Illinois Central. It may be well, however, to emphasize the importance of the screw machine or turret lathe for working up bar stock in the manufacturing toolroom, the punch press for stamping out gages in a fraction of the time required by hand, an automatic gear cutting machine where gears are cut in the toolroom, adequate milling machines of the plain and universal types and a full complement of grinding machines of ample size to handle the work and equipped where necessary with magnetic chucks.

The amount and kind of heat treating equipment will bear close investigation. An instance happened not many months ago in which a milling cutter worth upwards of $200 was absolutely ruined through the attempt to heat treat it in a furnace of insufficient capacity. It wouldn't take the loss of many such milling cutters to equal the price of a new furnace.

In conclusion, it may not be amiss to suggest that the tool supervisor or foreman, having perfected his organization, trained his men and standardized tool requirements, make an intensive study of his present toolroom machinery and equipment with a view to determining what could be accomplished with machines of more modern type. If savings can be effected show the "old man" the actual figures. If he has a grouch the first day you submit the figures, try him the next day from a new angle. He will think more of a man who, after forming his opinion, sticks to it. Whatever you do, never let him forget that the toolroom, as supervised by the efficient tool foreman, is the heart center of his entire shop and an important factor in railroad operation.

Portable cylinder saddle milling machine

By L. V. Mallory

Machine shop foreman, Missouri Pacific, Kansas City, Mo.

REALIZING the time and labor expended in most locomotive repair shops in fitting locomotive cylinder saddles to the boiler, the author has designed a simple, portable, milling machine which can be built at small cost, compared with the saving derived from its use in fitting saddles.

The vertical supports *A*, Fig. 2, which may be made either of 3¼-in. steel shafting or 2¼-in. by 3¼-in. steel tubing, are secured firmly at each end of the cylinder saddle by brackets *B*, Fig. 2, in such a manner that they can be adjusted by sliding them up or down to suit any required radius. The fulcrum shaft *C* is carried by the

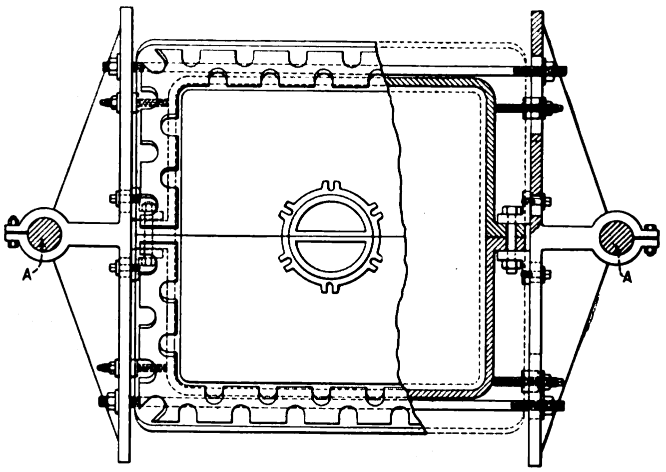


Fig. 1—Method of applying the fulcrum shaft support bracket to the cylinders

bearing located at the top of the vertical supports *A*. An ordinary cylinder boring bar can be used for this purpose without any alterations. The milling machine assembly is suspended from it.

The radius arm hanger, through which the fulcrum shaft passes, is made in two parts. The upper part *D* is secured to the fulcrum shaft *C* and contains a half-nut which engages with the fulcrum shaft lead screw. This nut can be disengaged at the will of the operator by means of a release spring and an eccentric mechanism. The fulcrum shaft lead screw is equipped on one end with a hand wheel *E*, which facilitates moving the miller head horizontally. The lower part of the radius arm hanger *F* is secured to the upper part *D* by bolts the heads of which slide in an annular tee slot which is concentric with the

central recess of the upper hanger *D*. This arrangement permits the miller cutter to traverse its work either radially or horizontally, which requires a difference in position of 90 deg. The lower part of radius hanger *F* contains two sockets which receive the radius arms *G* which are adjustable in the sockets and can be clamped rigidly at any desired point by means of cap screws. The lower part of *F* also contains a radius nut which engages the radius adjustment screw *H*. For convenience, this screw is operated by a hand wheel through bevel gears which are carried on a bracket.

The lower ends of the radius arms *G* are fixed in the miller frame which carries the worm gear and the miller cutter assembly, the feed screw yoke, the feed screw bevel gears, the feed screw counter shaft and the feed gears all of which are clearly shown in Fig. 4.

The worm shaft of the driving gear assembly terminates in a shank of suitable size and shape to fit the air motor socket which allows the motor to be mounted as shown at *I* Fig. 3. The driven worm gear is mounted within the housing which is on the cutter shaft. This shaft extends through the housing and through the miller frame bearings. It carries on one end the driving feed gear and

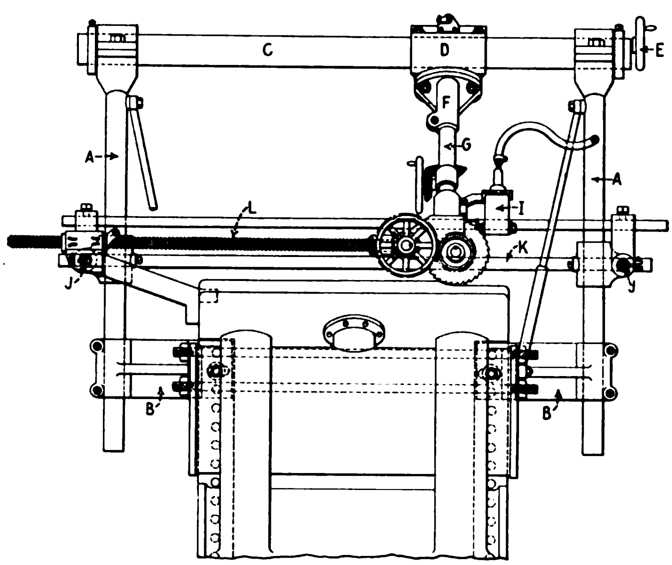

Fig. 2—Side view of the cylinder saddle milling machine

terminates on the other end in a tapered fit with a collar and nut for the purpose of securing the milling cutter when it is desired to mill in close places.

The main milling cutter is mounted on a shaft between the worm gear housing and the miller frame. When it is necessary to have the auxiliary cutter on the end of the shaft one should be used that is slightly larger than the main cutter between the frames. This will eliminate the removal of the regular cutter as it provides ample clearance for idling. The feed counter shaft carries on its outer end the feed gear which passes through the bearings in the frame as well as through the bearings in the yoke. The bevel gears are carried in this yoke with the driving gear mounted on the counter shaft and the driven gear on the feed screw.

The adjustable brackets are secured on each vertical support *A*, which, in turn, secure the transverse anchor rods *J*, Fig. 3. These rods terminate in eyes, through which passes the longitudinal anchor rod *K*, Fig. 2. The removable feed screw nut-assembly is hinged to the anchor rod *K*. The feed screw split nut assembly consists of two saddle nuts that engage the feed screw *L*, Fig. 2. These nuts are contained in a cage in such a manner that they can be engaged or disengaged from the feed screw at the will of the operator, by means of the operating rod *M*, Fig. 2, and engaging the split nut operating slides. The lower part of the split nut housing forms a hook which hinges on the anchor rod *K* which is closed by filler blocks in such a manner that the whole assembly is free to swing on the anchor rod.

From the manner in which the feed screw split nut

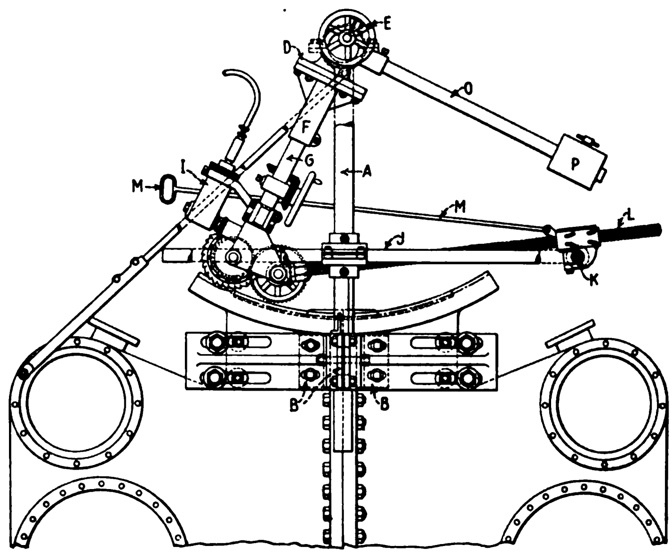

Fig. 3—Front view showing the method of mounting the cylinder saddle miller

hinges on the anchor rod *K* and the feed screw yoke hinges on the shaft connecting it with the miller frame, it is obvious that the miller head will be drawn toward the anchor rod *K* and that the feed screw *L* will always be in perfect alinement at all positions of the miller-head.

When milling the side flanges, the feed screw split nut

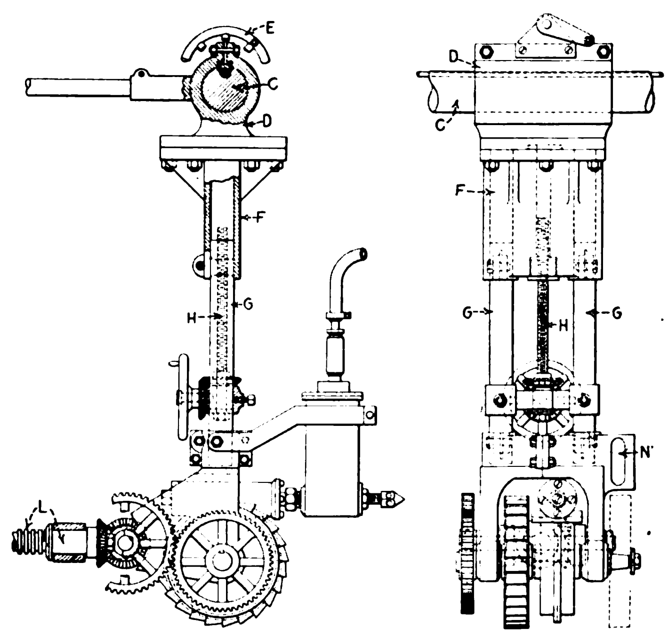

Fig. 4—Miller head and radius arm for the cylinder saddle radial miller

is removed from the rod *K* and placed on the transverse anchor rod *J*. The Miller-head is turned 90 deg. from its former position. A guide rod is then passed through the slot *N*, Fig. 4, which is secured at each end to the anchor rods *J* by suitable brackets. It can be slid along the rods *J* and fastened at any desired point but they must be set

at a different point each time a longitudinal cut is taken in order to move the cutter over in position for a new cut. When making these longitudinal cuts, the saddle nut is disengaged from the lead screw, allowing the radius arm hanger to slide along the fulcrum shaft *C* as the cutter advances. A spacer bracket attached to the rod *J* and heels against the cylinder saddle serves to stiffen the anchor rod *J* when making the longitudinal cuts. The upper part of the radius arm hanger *D* has a socket in which the counter weight lever *O*, Fig. 3, is fixed, which carries the counter weight *P*. The vertical supports *A* are diagonally braced by adjustable braces whose lower ends connect with the valve chamber or cylinder head studs. Referring to Fig. 1, the fulcrum, shaft support brackets have two horizontal slots in each end through which pass the tie rods or studs. Spacer screws also are set in these slots. These slots make it possible to fit the brackets to different widths and styles of cylinder saddles, allowing the tie rods to lie up close to the neck of the cylinder saddle, thus insuring a more rigid anchorage of the brackets. The spacer screws serve to stiffen the support brackets at the points where the tie rods exert their pressure. They also engage with specially designed nuts that have projecting lugs which fit in the tie rod slots. These nuts have shoulders or flanges that lap over the edges of the slots on the inner face of the support brackets. The spacer screws are of sufficient length to pass through the nuts and to the end surfaces of the neck of the saddle.

Near the center of the support brackets are four smaller slots through which pass the cap screws which screw in the angle brackets located on the inner surface of the support brackets in such a manner that the splice flanges of the cylinder saddles come vertically between them. The part of the angle brackets that meet the splice ranges are slotted so that an alinement can be made with one of the bolt holes already in the splice flanges. A clamp bolt nut is put through the angle brackets and splice-flanges when the clamp bolt is tightened. The support brackets *B* are adjusted laterally in such a manner that the center of the receiving sockets for the vertical supports *A* line up vertically with the center of the cylinder saddle. When this adjustment is made the cap screws are tightened, thus insuring a rigid central support that holds the fulcrum shaft accurately in position. The spacer screws are then adjusted until they press firmly against the neck of the cylinder saddle after which the tie rods may be drawn tight. There are milling cutters on the market having inserted teeth that can be used to advantage in this machine. The machine can be driven by either an air or an electric motor.

Pointers on forging machine dies*

Die design and construction not a one-man job—Co-operation between forge shop and tool room desirable

THE success of forging machine dies in railroad shops depends on their correct design, the use of proper materials in their construction and accurate die alinement in the forging machines. Experience has shown that where greater heat resisting properties than possessed by carbon steel are required, chrome, or tungsten alloy steel should be used, the application being in the form of inserts wherever possible in order to reduce the first cost.

The principal causes of die deterioration are generally recognized as abrasion, heat and pressure. Excessive pressure is the least of forging die problems as the gripping dies and heading tools are generally heavy enough to withstand the forging pressure. Abrasion, that ever present factor which causes ultimate deterioration of dies but not necessarily their early failure, cannot wholly be prevented. The skill of the designer plays an important part in designing dies in which excessive abrasion takes the longest time to develop. The constant jets of water which should play on the dies while in operation are depended upon to minimize abrasion by working the scale out of the impressions as well as keeping the dies cool.

Observation has shown that heat is the greatest enemy of satisfactory die life. This fact may be readily observed where the die impression or header is surrounded with hot stock in its operation, such as is the case with bushing dies, pin slot punches, or castellated nut dies. Dies subject to a great amount of heat, or used for the production of a large amount of forgings in rapid succession, held to certain close limits, should be made of alloy or other steel with high heat resisting qualities. Dies constructed of steel for this class of work give more service, better forgings and are less expensive to maintain.

An example of a case of this kind may be mentioned as follows: A set of bushing dies was sunk in cast iron blocks with die block steel headers and punches, 500 to 600 bushings being about the limit of production of these dies without re-working. The cast iron dies were replaced with steel dies (45 to 50 point carbon) and the production increased to 1,500 bushings before repairs were needed. Even then it was simply necessary to straighten up the edges where they had turned in from heat and pressure.

It must be understood that cast iron dies should not be entirely dispensed with, for in certain forging operations such as welding, cast iron gives better results than steel. Again, where a number of forgings are needed which will never be duplicated, cast iron is the logical material to use as it represents a much smaller investment than steel and does the work just as well. Die service depends to a certain extent upon the skill of the operator in making sure that the material worked with is properly heated and gaged so that when the dies close it will be upon the proper amount of material to make the forging. All this means longer life of the dies and less up-keep expense on the machines.

Co-operation between the forge shop and the toolroom go a long way toward reducing the cost of maintenance, and the construction of new dies. It is no one-man's job. Exchanging ideas brings the best results.

In preparing a paper on this subject your committee

*Abstract of a regular report of the Committee on Forging Machine Dies presented at the thirteenth annual convention of the American Railway Tool Foremen's Association held in Chicago September 2, 3 and 5, as reported on page 639 of the October *Railway Mechanical Engineer*. The report was read by Chairman E. A. Hildebrandt, tool foreman of the Cleveland, Cincinnati, Chicago & St. Louis at Beech Grove shops, Ind., who is the new president-elect of the association. Other members of the forging machine die committee included C. B. Heingarten, Chicago & North Western, Chicago; C. C. Burke, Chesapeake & Ohio, Peru, Ind.; A. C. Roepke, Union Pacific, Los Angeles, Cal., and C. Petran, Chicago, Milwaukee & St. Paul, Milwaukee, Wis.

is aware of the fact that there is perhaps little information we could offer that is entirely new, but we are pleased to be able to furnish information regarding dies which we feel have been a real factor in reducing the cost of shopping locomotives and cars.

Following are several drawings and explanations of practices on the Cleveland, Cincinnati, Chicago & St. Louis at Beech Grove shops, Ind.

S-Wrenches—These are made on a 4-in. forging machine and a Bradley hammer. The dies are made of die block steel (55 to 60 point carbon). The Bradley hammer dies are hardened and tempered, the forming and punching die and headers not being hardened. The first operation in forging S-wrenches is cutting to proper length a piece of machine steel 1/4 in. smaller

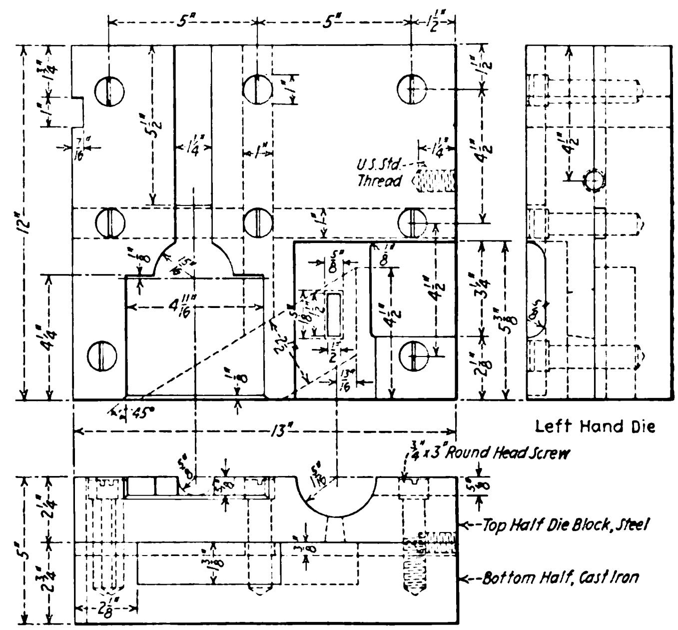
S-wrench made on Bradley hammer and 4-in. forging machine

than two times the dimension *D* in the wrench drawing. Next a ball is formed on each end and the handle of the wrench is drawn out; the ball on each end is flattened to approximately the finished side of the outside diameter of the jaws of the wrench, these operations all being done on Bradley hammer balling dies. The next operation is done in the forging dies with the first operation header, which punches and forms the jaw; the wrench is then passed to the next impression and the header, which is 1/16 in. larger than the punching header, forms the outside dimensions, leaving enough stock in the jaw for machining the wrench to standard size. The fourth operation consists of bending the wrench to the proper shape on a small bending machine which is near the forging machine. The second, third and fourth operations are all made with one heat.

All wrenches are forged smaller in the jaws than the nut size and are milled to size with a pair of straddle cutters. The wrenches are held in an air clamp while

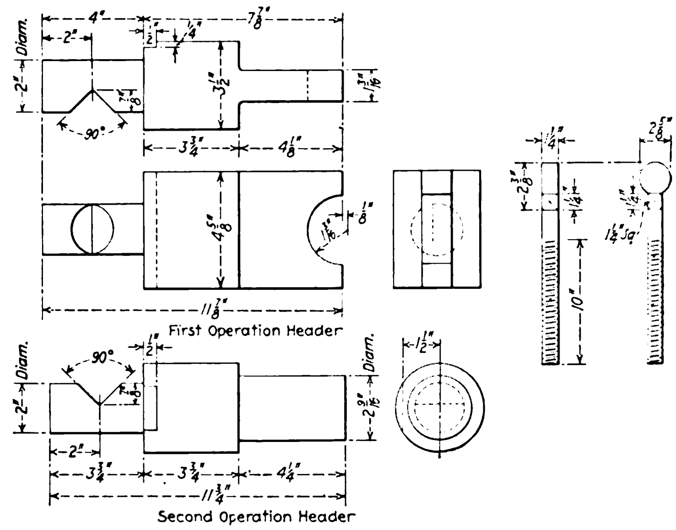


Forging die for 1 1/4-in. wedge bolt

milling, the burrs being ground off and the wrenches then case hardened.

The production of 1 3/4-in. wrenches on the Bradley hammer is three an hour; the production on the forging machine is ten an hour, this production increasing on the smaller size wrenches.

Wedge bolts—The dies for wedge bolts, made of die block

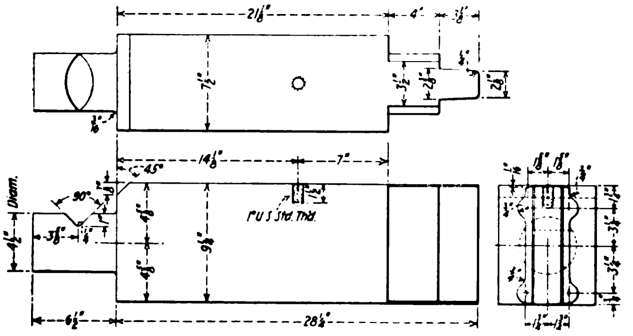


Header dies for 1 1/4-in. wedge bolt—Dimensions of bolt

steel backed with cast iron, are used on a 2 1/2-in. forging machine. The diameter of the wedge bolt head for the 1 1/4-in. bolt is 2 5/8 in., the thickness being 1 1/4 in. and it takes approximately 5 in. of stock to make this bolt. The work is done in one operation by allowing the header to enter the die before it strikes the material. The header upon entering the die begins to form a pocket in which the stock is carried forward until it forms the head of the bolt. The surplus stock or flash flows into the 1/4 in.

clearance space between the header and the dies when the header is at the end of its stroke. This flash is trimmd off in the next pass of the dies and the slugs drop out at the back of the die through the 1⅜-in. by 2½-in. slot shown on the forging die drawing.

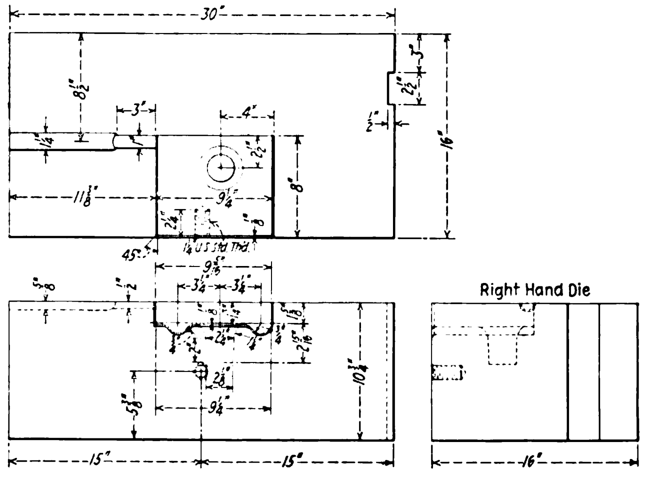
The bolts are taken to the punch press and in two operations the head is sheared to a limit of .002 in. in diameter by being punched through a shearing die. The bolts are then threaded, sent to the storehouse and ordered out as needed. A tolerance of .007 in. between the size of the bolt head and the hole in the wedge is maintained. There is no unnecessary filing or grinding to do; the wedges and the bolts are ready for application when ordered from stock.



Header die for radius bar lifter

The idea of making the die in two parts was mainly to simplify machining operations. Thirty wedge bolts is the average production for an hour on the forging machine; bolts are trimmed to size at the rate of 50 an hour.

When a header of this kind breaks, the broken end is cut off and a slot is cut in the body of the header which then answers the purpose of an adapter for a new header blade. The blades are held in place by bolts of suitable size, which the snugly fitted in both the blade and adapter.



Forging die for radius bar lifter

This method of repairing saves considerale time and material as the blades for various kinds of headers are kept in stock and when one breaks all that is necessary is to change blades. Otherwise, it would mean a complete new header. Die block steel costs money as well as time to machine it. Here is a chance to save several dollars on each header if you are not already repairing them this way.

Radius bar lifter boxes—These boxes are forged in one operation. The dies are sunk in 11-in. by 16-in. by 30-in. cast iron blocks with a die block steel header and are used on a 7-in. forging machine.

As it would be difficult to make steel flow in one operation to make a forging of this kind, iron is used which is cut into 2⅝-in. by 5-in. by 8-in. blocks which are heated up to a white heat and a porter bar welded on. They are then passed into the dies from the top of the machine. It is more of a squeezing than an upsetting operation and it is very essential that the metal be thoroughly heated so that the bearing ends of the box will fill out with the least resistance and minimum strain on the dies and machine. An everage of four boxes an hour can be produced with these dies. The trimming is all done by the machine operator.

Small spring bands.—The first operation in forging small spring bands is to cut material of the proper thickness and width and bend it on an air machine to form a rectangle approximately the size of the band, allowing enough stock in length to make a scarf weld. The second operation is performed in the dies, the partly finished band being heated to a welding heat at the scarf and placed in the pocket of the dies; the header passes through the band and forms and welds it, the surplus stock, if any, flashing out either at the front or back end of the die. This flash is trimmed off by the machine operator and the band is ready for application to the spring leaves.

Small spring band dies and header

Large spring bands—The first operation in forging large bands is to shape and bend the stock on the bulldozer as shown in the insert sketch. Enough stock is allowed when cutting to length to assure proper thickness of the spring band on the heavy end. In this set of dies it will be noticed that the header does not pass through the spring band, but that the inside dimensions of the band are formed by the bosses on each half of the dies. The header strikes the long end of the partly shaped band, and welds and forges it to thickness in one operation. The ⅞-in. groove cut in the dies is an outlet for surplus stock.

It is not necessary to heat the band all over, but to a good welding heat on the ends that are to be upset and welded. A back stop must be used to hold the band in the dies. These dies, used in a 4-in. machine, are sunk in cast iron which we find is much better than steel for this kind of work. Steel checks much quicker than cast iron and forgings are more apt to stick in the dies. The headers are made of die block steel. An average production of 10 bands an hour is secured with these dies.

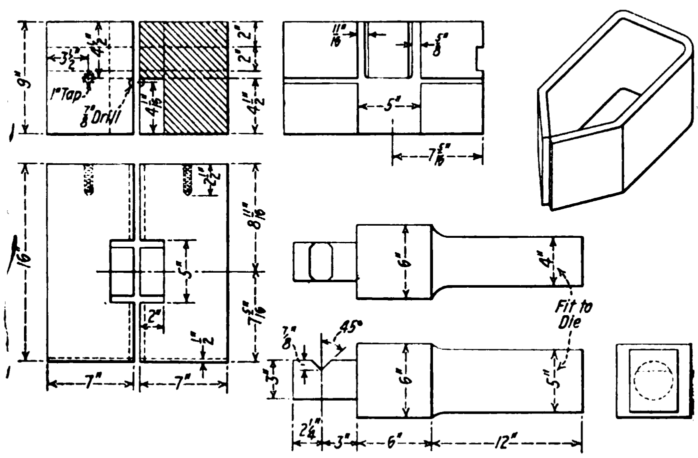
Brake beam safety straps—These straps are made of 2-in. by 2-in. by ⅜-in. angle iron in one operation on the

bulldozer. The header is mounted on a wrought iron plate bolted to the head of the machine. This header has a die block steel insert which contains the three 13/16-in. punches and is removable. Should it be necessary to change punches, the insert is removed by taking out two fillister head set screws; standard boiler punches (made of 90 point carbon steel) which are kept in stock are applied. The change can be made with very little delay to production, as it is not necessary to remove the header from the machine.

The die portion of the former is made of machine steel and is mounted on a cast-iron sub-plate bolted to the bed of the machine. The punching die is made of tool steel and is held in position by two dowel pins and two screws.

The old way of making the straps required the bending, laying out and drilling operations as well as extra trucking. The laying out, drilling and a part of the trucking expense has been eliminated as the work is all done (with the exception of shearing to length) in one machine. The straps are heated in an oil-burning furnace and a production of 40 finished straps an hour is realized.

Brake staffs—A set of sliding block dies is used in a 7-in. machine for upsetting the square part of a brake staff. The bodies of the dies are made of cast iron and



Large spring band dies and header—Insert shows band after first operation of bending on bulldozer

the sliding block and header are of die block steel. The cast iron section of the die holds the work and is milled with a 1/32-in grip.

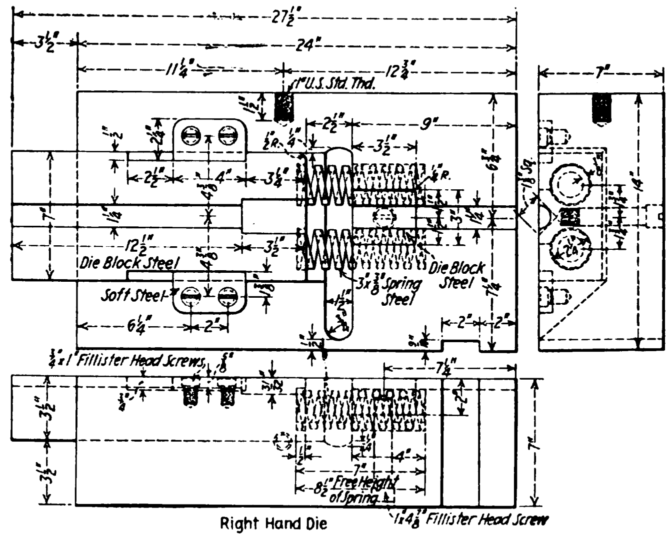
The sliding block is bored to the size of the stock and contains the impression of the square. As the square part on the brake staff is 2 ft. 10⅛ in. from the end it is necessary to drill a hole ⅛ in. larger than the size of the stock through the header through which the stock is passed. It is essential that the bars for the brake staff all be the same length to avoid buckling in the header and crosshead on account of too much stock.

A 1½-in. steel bar is placed in the hole in the crosshead, cut to the proper length so that when the crosshead comes forward the bar strikes the end of the brake staff at the same time the header strikes the sliding block which carries the stock forward and forms the square. The brake staffs are all gaged from the back stop on the machine.

The scale from the work drops out through the 1½-in. channel shown on the drawing. On the return stroke of the machine the springs push the sliding block back to its starting position.

Fourteen brake staffs an hour can be squared with these dies. It is very important that the heats be gaged the proper distance from the end of the bars, to avoid the possibility of damage to the dies if allowed to close on improperly heated stock. The length of the heats must be gaged in proportion to the amount of material to be upset. Too long a heat will cause the stock to buckle.

A die house is provided at Beech Grove where all dies and templates used in the forge shop are kept. There are over 850 sets of dies and special punch press tools which are looked after by one man, who keeps the dies and headers in relative order, cleans them and wipes them with oily waste to prevent rusting, checks them in and

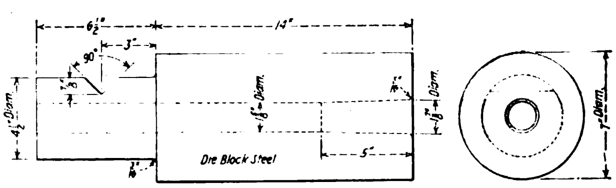


Sliding block forging dies for 1¼-in. brake staff

out and sends them to the toolroom whenever repairs are needed.

The dies are all numbered, blocks with two sets of dies in them having two numbers. The machine operator is furnished with a set of checks which are used only for checking out sets of dies as needed. The check is hung on a board together with the number of the die. When the job is completed the dies are returned, inspected, and if in need of repairs are sent to the toolroom. This system eliminates the practice, sometimes followed where there are duplicate sets of dies, of obtaining another set of dies without reporting that the set which was in use failed or needed repairs. It also assures one good set of dies while another is being repaired.

Before the die house was built, dies were left around



Header die for 1¼-in. and 1⅜-in. brake staff

the machines in the shops, taking up valuable space, and it often happened that they were covered up with heavy material. Sometimes they were set outside and exposed to the elements and in winter they had to be dug out of the snow. All this caused unnecessary die deterioration. Cast iron or steel such as is used for dies will oxidize to a depth of .010 in. to .015 in. over a period of 90 days when kept exposed to the elements. This means that a die which had .020 in. grip has rusted to the extent that it has no grip at all. The remedy is to take it to the toolroom, grind or plane some off so the dies will hold—all an unnecessary waste of time and material. Dies are invested capital and must be taken care of in order to

give the best results and yield the greatest returns from the investment with the least possible amount of maintenance cost.

Maintaining the precision reverse gear

By A. T. E.

In order properly to maintain the Franklin Precision reverse gear, it is necessary to grind the seats of the slide valve occasionally and to renew the cylinder packing leathers. It is impossible to remove the valve operating arm without taking out the back cylinder head. The two cast iron face plates shown in the sketch were made for the purpose of regrinding the joint between the slide valve and its seat. The work of grinding in a slide valve has often been a bigger job than the enginehouse foreman likes to admit, especially when locomotives are being

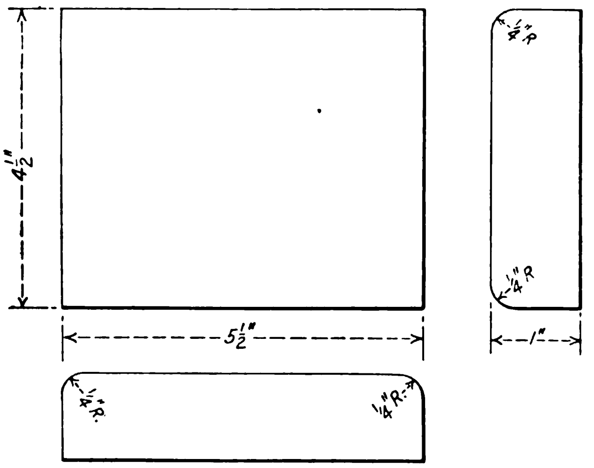


FIG. 1

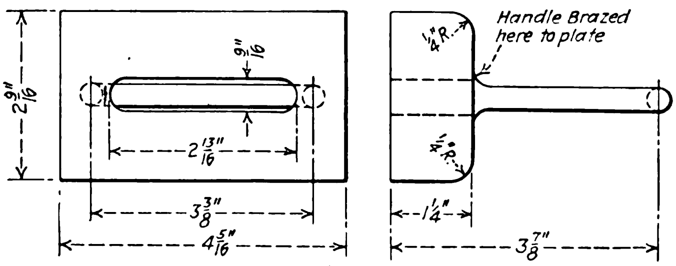

FIG. 2

The face plate shown in Fig. 1 is used to grind the slide valve—Fig. 2 is for the valve seats

turned on short time. However, by the use of these face plates, a mechanic has only to remove the slide valve chest cover and the slide valve in order to grind the seat with the face plate shown in Fig. 2 of the sketch. The valve is ground with the face plate shown in Fig. 1 and the reverse gear is then assembled for service.

In order to keep the face plates true, they should be machined occasionally and frequently lapped and ground together. By using these plates reverse gears can be kept in good condition with little loss of time and there will be few occasions where a locomotive will be held for repairs to the reverse gear only.

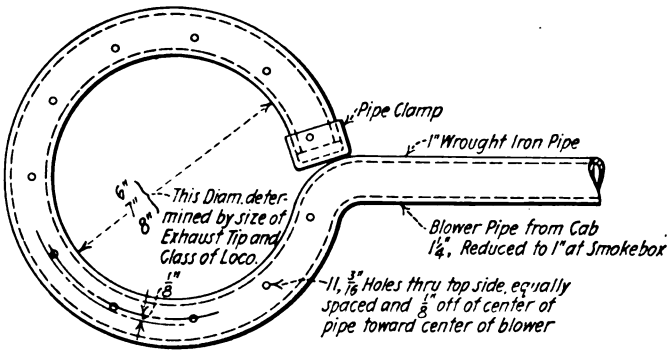
In order to renew the reverse cylinder cup leathers, it is necessary to remove both the front and back cylinder heads. There being no counterbores in either end of the cylinder it is a difficult job to slip a piston through with new cup leathers. However, by assembling the piston at the bench, the back cup leathers can be guided into place by the use of thin tin strips. One objection to this method is that it is usually quite difficult to get the back leather into the cylinder and the triple screw into the piston trunk at the same time.

A better way of doing this job is to slip the back cup leather and the piston follower from the front into the back end of the cylinder at the beginning, and then place the indicator block in the cab in the extreme forward position. As the mechanic starts the screw into the piston trunk, he pulls the balance of the piston parts as far into the cylinder as possible by rotating the hand wheel in the cab as if reversing the engine. Usually the follower stud holes in the piston head will not line up with the follower studs when reassembling the piston. When this occurs, run the piston ahead a few revolutions of the hand wheel and clamp a wrench on the flat end of the piston trunk, turning it a little to the left, and at the same time hold the screw from turning. Then run the piston to the back of the cylinder until the studs are inserted in the follower stud holes in the piston head. Screw a couple of nuts on the studs by hand and move the piston to the front cylinder where all the nuts on the studs can be tightened more conveniently.

Locomotive blower pipe

The Minneapolis & St. Louis has experimented recently with a blower of the design indicated in the drawing which apparently has important advantages over some of the other types commonly used.

This blower is circular in shape and made from common wrought iron pipe in the shop. The blower lies flat on the table plate, fitting snugly around the outside of the nozzle tip. The end of the blower is closed with a pipe cap and is attached to the blower line in the usual manner. Holes 3/16 in. in diameter, equally spaced and usually about 1½ in. apart are bored in the top of the blower

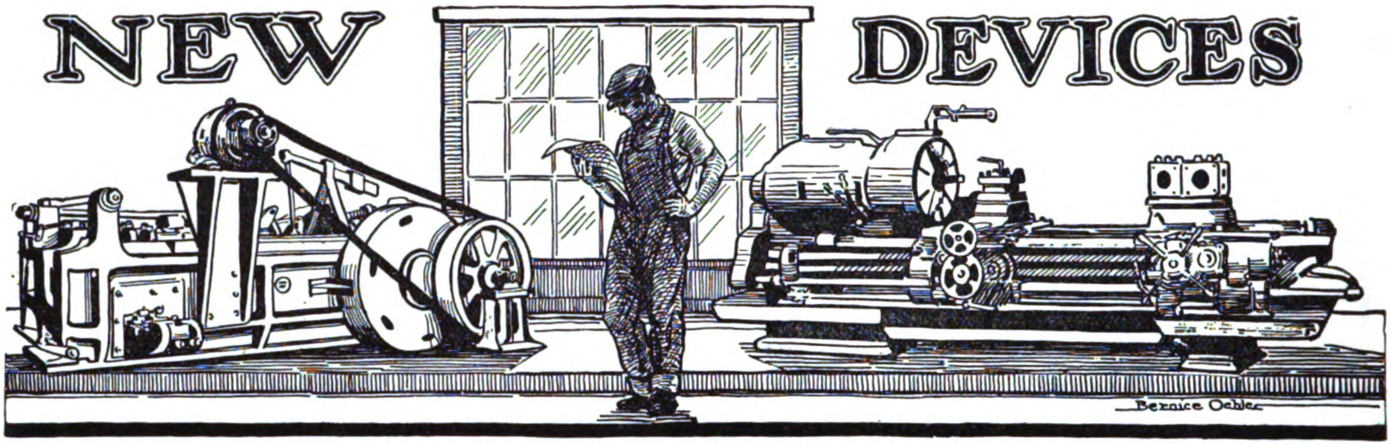


Locomotive blower which has given good results on the Minneapolis & St. Paul

⅛ in. off center and pitched so that the several jets of steam converge at the choke of the stack.

The diameter and size of the blower and number of holes is determined by the size of the nozzle opening. On engines having a 4-in. tip, ¾-in. pipe is used and on engines having a 6-in. nozzle tip, 1-in. pipe is used.

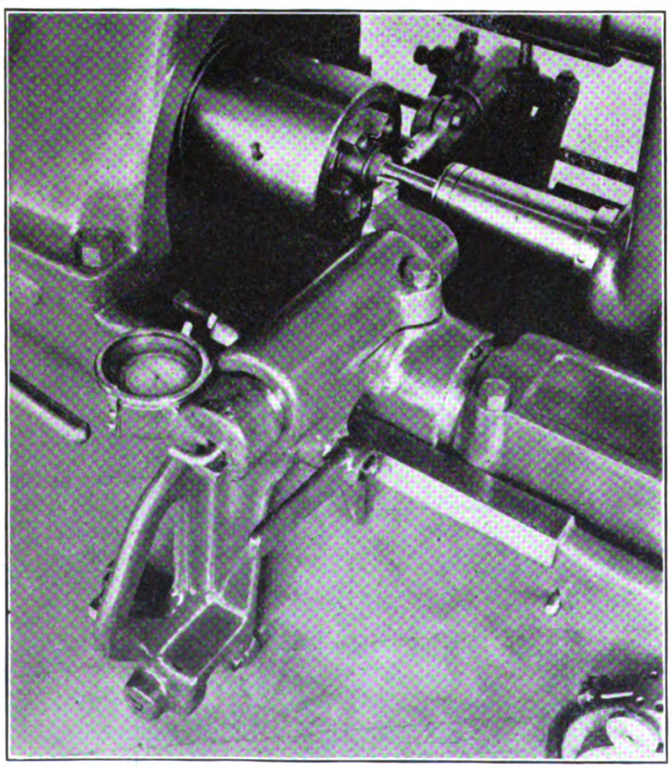
Actual tests have shown that this type of blower uses only one-fourth the usual amount of steam required for blowing up a boiler. It is far more efficient and in addition is practically noiseless, a desirable feature particularly around passenger stations and in enginehouses. Some of these blowers have been in service for more than a year, and require practically no maintenance.



Improvements in Bryant internal grinders

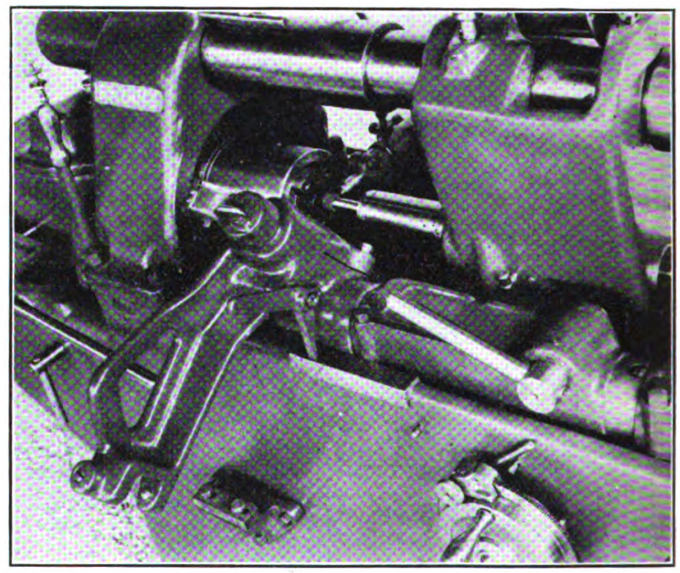
FOUR major improvements have been made by the Bryant Chucking Grinder Company, Springfield, Vt., which can be applied to any standard Bryant hole grinder. All of these improvements are found on the No. 6 semi-automatic hole grinder which is particularly adaptable to railway shops.

The first of these improvements is an automatic size indicating attachment, the use of which enables the operator to know when the desired diameter of a hole has been reached without the necessity of constant measuring with a plug gage. When in position, it does not interfere with the movements of the operator. It consists



Automatic size indicating attachment applied to a No. 6 Bryant internal grinder

primarily of a diamond gaging point in contact with the bore of the hole being ground, a dial indicator and means for communicating the movement of the gaging point to the dial of the indicator. All working parts, including the indicator, are enclosed to protect them from water and grit. A glass cover is fitted over the dial. The gaging point is a diamond carried by a small arm that projects into the hole. The diamond is smoothly finished on the contact surface to the radius of the smallest hole to be ground. The whole device is movable endwise by means



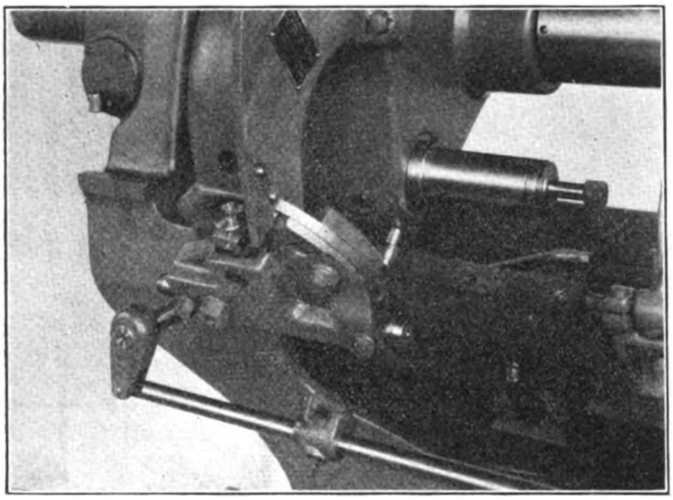
Adjustable wheel truing device in position

of a lever so that the gaging point may be instantly withdrawn from the hole and swung out of the way when changing the work.

It is a simple matter to set up the indicator. The first piece ground is finished to the desired size, being checked with a master gage. The gaging point is then brought in contact with this finished surface of the hole and the dial indicator is set at zero. All subsequent holes ground will be to the correct size when the dial indicator registers zero. After the grinding wheel has been started in a piece of work, the gaging point is brought into the hole, the diamond resting against the wall of the hole opposite the grinding wheel. The dial, previously set to the size of the hole required, immediately registers the amount that the hole is smaller than the normal size. This dial is graduated to indicate tenths of thousandths of an inch.

In order to prevent the wear of the diamond gaging point, especially when grinding holes with a rough surface, means are provided for relieving the diamond a few

thousandths from contact with the surface. When the rough surface or scale in the hole has been ground out, the diamond is brought back into contact with the surface of the hole. If desired, the diamond may remain in contact with the wall of the hold throughout the grinding. As the diameter of the hole approaches the normal size, the point of the indicator moves toward zero. When the pointer is at the zero mark, the operator knows that the hole is finished to the required size. He then withdraws



Control bar adjustment for grinding tapers

the grinding wheel and takes out the work. No plug gaging is necessary.

The success which has been obtained with this attachment is attributed chiefly to the control, which is on the same general principle as used for the Bryant wheel slide. The indicator head is attached to a heavy bar with bearings far enough apart to give control. The bearings are wholly enclosed and protected against grit. The bar moves longitudinally and swings in the same bearings, thus eliminating the need of gibbed cross slides. For holding the contact point in position, an arm is provided which is located by the control plate. This arm also serves as a handle for operating. At the same time, maintenance of accuracy has been made possible without sacrificing ease of operation.

An adjustable wheel truing device, shown in one of the illustrations, has been developed for use in connection with the Bryant sizing indicator. A micrometer adjustment is provided for moving the diamond in or out. With this arrangement it is an easy matter to set the diamond exactly in line with the diameter of the finished hole. If desired, the diamond can be set so that the wheel is dressed every time it is withdrawn from the finished hole, the diamond being set so that only a fraction of a thousandth of an inch of the wheel is removed, just enough to clean the surface and straighten the wheel. One pass of the wheel in front of the diamond as it is withdrawn from the hole is all that is necessary and this is automatically taken care of without any extra motion.

The chief advantage of this method is that the wheel is always straight and in perfect cutting condition, thus insuring better work both with regard to size and finish. It has also been found in many tests that the loss of wheel from dressing is less with this method than when the wheel is trued only when the operator happens to think of it. This diamond holder is operated by a lever conveniently placed so that it can be swung up out of the way when chucking or removing the work.

To facilitate the setting up of the machine for grinding taper holes, a micrometer adjustment, shown in one of the illustrations, has been provided for the control bar on the wheel slide. The swinging plate is accurately graduated up to a 45-deg. included angle. By the use of a special plate, an included angle of 60 deg. can be ground.

The flat control plate has been replaced with a round bar held in a swivel plate. This control bar is located in alinement with the slide bar when grinding straight holes. It engages a roll in the cross feed screw which minimizes wear. If wear does occur after considerable use the control bar can be turned in its seat slightly without losing its alinement. The control bar is clamped by two screws. The swivel plate, which carries the bar, is also clamped in place by two screws.

A hand lever has replaced the hand wheel as standard equipment for operating the chuck on Bryant grinders. The chuck operating lever is conveniently placed and helps increase the production with less exertion.

Solutions to prevent corrosion

ACIDS, alkalies, and moisture are the three main factors which cause the corrosion of steel railway rolling stock. Tests have proved that it is important that a protective coating should penetrate the exposed pores of the metal or surface to be protected. It should adhere firmly and fill every hole and crevice to seal the surface against the destructive action of water, acids or alkali.

The Quigley Furnace Specialties Company, Inc., 26 Cortland street, New York, have placed on the market a corrosive preventative solution, known as Triple A. These solutions are compounded from coal tar derivatives, carefully heat treated and are claimed not to crack, chip or peel. They contain no vegetable or animal oils, grease or turpentine and are said to form a lasting union with the surface covered which does not allow moisture or gases to creep through to the metal. This prevents oxidation and the pitting action of electrolysis.

These solutions have been put to severe tests. Small crucibles about 3 in. high and ½ in. in diameter at the top, made from a porous clay were lined with the Triple A solution. In these crucibles, the following chemicals were placed: saturated solution of caustic ammonium fluoride; concentrated prussic acid; arsenious acid, and mercuric chloride. The crucibles were allowed to stand for two weeks after which the chemicals were removed. The acids and alkalies had not affected the Triple A solutions. There was no leakage through the porous clay which would have indicated at once that the solution had been eaten through by the chemicals.

A piece of 1/32-in. sheet steel was painted on both sides with the solution and after it had dried, was bent back and forth without showing signs of cracking or peeling.

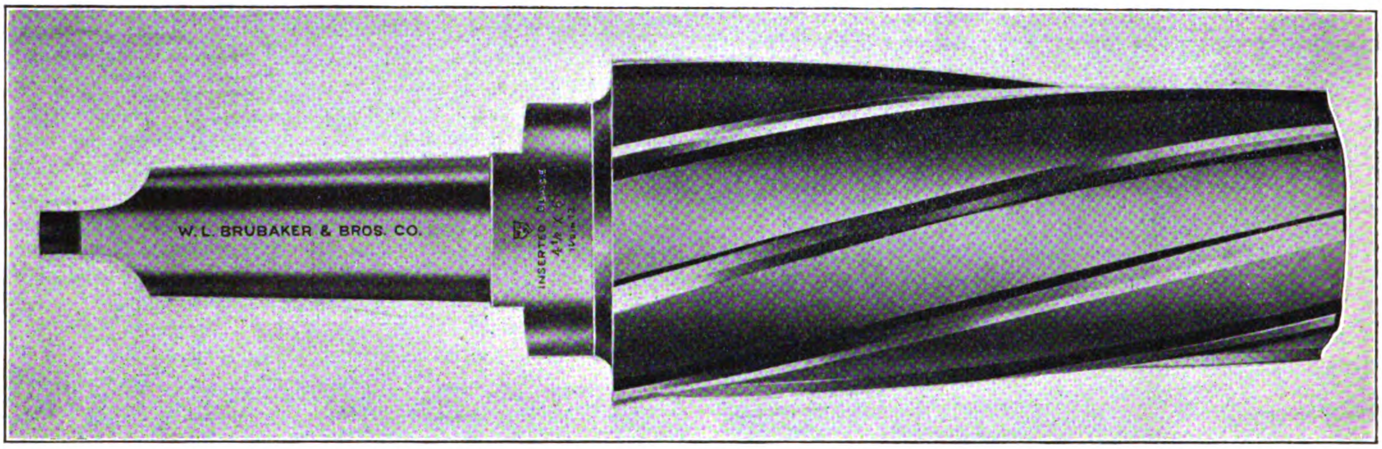
These solutions are applied with a brush on a clean metal surface, free from grease, dust or oil. They spread easily, leaving a firm, smooth and elastic surface. Triple A solutions are furnished in several colors, the usual standard base coat being black. Over this black may be applied additional Triple A colors, such as maroon, olive-green, deep-green, yellow, etc. The black solution will cover 300 to 400 sq. ft. of surface per gallon on iron or steel.

Spiral inserted blade reamer

WHEN the cutting edges of solid reamers are worn down to the point where they can not be reground, it is necessary to scrap the tool. This is a loss that can be reduced to a minimum by inserted tooth reamers. Such a reamer has been designed and placed on the market by the W. L. Brubaker & Brothers Company, 50 Church street, New York. The body of this reamer is made of a steel which can be subjected to abuse without any possibility of breaking or twisting.

The blades are made of high-speed steel and are heat treated so as to stand great strain without breakage. New blades can be furnished but as they are inserted by a special process, the reamer body should be sent to the factory for this work in order to obtain the best results.

The reamer can be obtained in any taper and size above 3 in. in diameter.



Brubaker spiral inserted tooth reamer

Atkins Silver Steel hacksaw blade

IT has been generally recognized among the users of power hacksaw machines that it has been impossible to obtain the maximum production from these machines as the average hacksaw blade will not stand up under high speed cutting. The E. C. Atkins & Company, Indianapolis, Ind., now manufactures a hacksaw blade which it is claimed will withstand the hardest service to which it can be put.

The success of the Silver Steel blades is attributed to the quality of the steel from which they are made. Another important quality of these blades is the heat treatment which they receive. As a result, each blade will give the same amount of service with a very small variation and with very little variation in the speed of the cut from the first to the last. The teeth are carefully milled with round gullets and properly pitched and are set even on each side of the blade. The performance of these blades is shown in the table.

Silver steel blade (new)			First Tungsten alloy blade (new)		
	Time			Time

Atkins steel blade cutting 4⅝-in. steel gear blanks

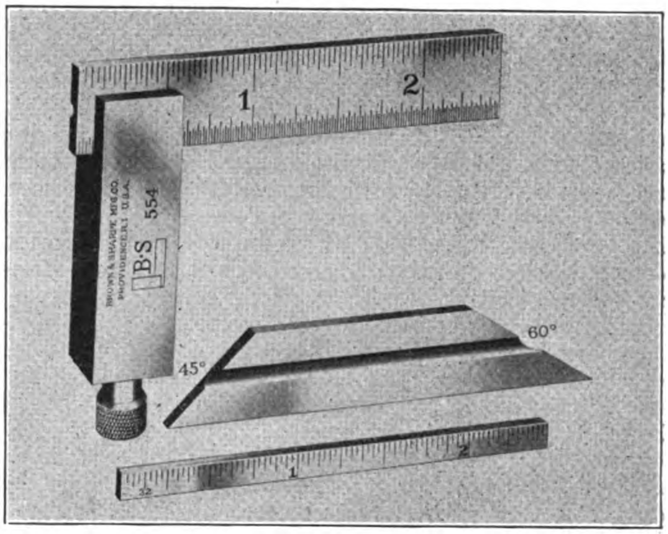
One Silver Steel blade made 400 cuts in the same time that the six blades of tungsten alloy steel made 298 cuts. The six tungsten blades averaged 49 cuts apiece.

Adjustable square with many uses

An adjustable square which can be used as a graduated square, as a depth and height gage, for laying out work, for grinding tools, particularly drills, for checking a mitre, for squaring up small slots, for testing a 60 deg. angle and for measuring the depth of counterbores or holes has recently been made by the Brown & Sharpe Manufacturing Company, Providence, R. I.

It is furnished with three blades. Referring to the illustration, with the wide blade, the tool becomes a graduated square or depth gage. This blade and the bevel blade are 24/64 in. wide. The bevel blade is suitable for grinding thread tools and laying out angles and mitres. It has both 60 and 45 deg. angles and is reversible. The narrow graduated blade which is 1/8 in. wide enables the mechanic to reach inaccessible spots. The clamping device holds the blade in the body firmly and accurately. The square is easy to use; simply insert the blade to the position desired and tighten the knurled nut.

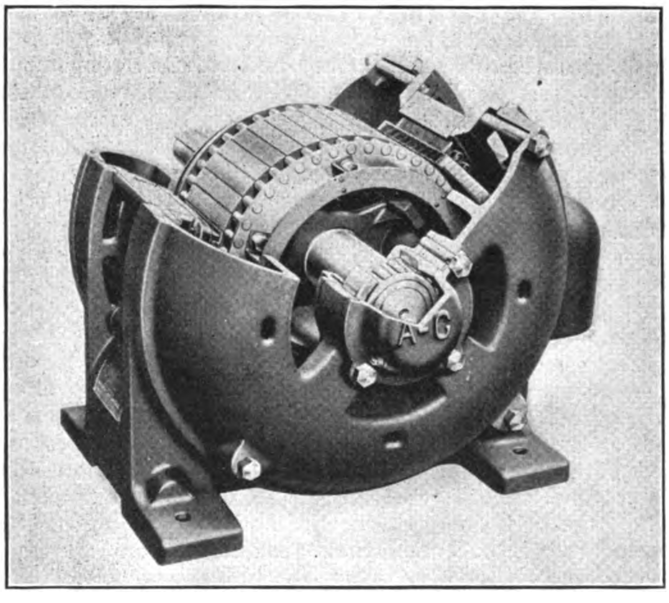
The blades are tempered and carefully ground and the graduations are clean cut and easily read. The body is hardened and ground.



Brown & Sharpe adjustable square with reversible blades

Roller bearing type motor

After two years of experimental and development work, the Allis-Chalmers Manufacturing Company, Milwaukee, Wis., has placed on the market a complete line of 25 and 60 cycle squirrel cage and slip ring induction motors equipped with Timkin tapered roller bearings. The Timkin bearing was selected only after very careful consideration of the many questions of design and operation. After designs of bearings and mountings had been made, a number of motors of various sizes were built and tested under actual operating conditions of belt, gear, chain and coupled drives, a sufficient length of time to insure satisfactory service. The Timkin bearing has been used because of its ability to withstand continued heavy radial and thrust loads without undue heating or appreciable wear. It is particularly suited to heavy service and will operate satisfactorily at the high speeds found in the general purpose induction motor. Because of the rolling action of the bearing, there is practically no wear so that the factory adjusted air gap is maintained indefinitely, eliminating any possibility of the rotor striking the stator.



Sectional view of Type AR roller bearing motor

The important question of lubrication is greatly simplified, as grease is used requiring very infrequent attention on the part of the operator. The bearings have grease tight enclosures effectively excluding dirt or abrasive matter that might cause undue wear of the bearings. The mounting of the bearings is very simple, being only a light press fit for both the cone and cup, and not requiring the use of a lock nut or other means of holding the races in place. This also facilitates the removal of the bearings whenever necessary.

In addition to the bearings, special attention has been given to many other features of design of this line of motors. The frame is made of steel with feet cast integral, to withstand shocks. The coils are thoroughly insulated and baked in a water-proof varnish. The openings in the housings and frames for ventilation are so placed in vertical planes, that falling objects cannot enter the motor.

This motor can now be obtained in all ratings, 25 and 60 cycle, 200 hp. and smaller.

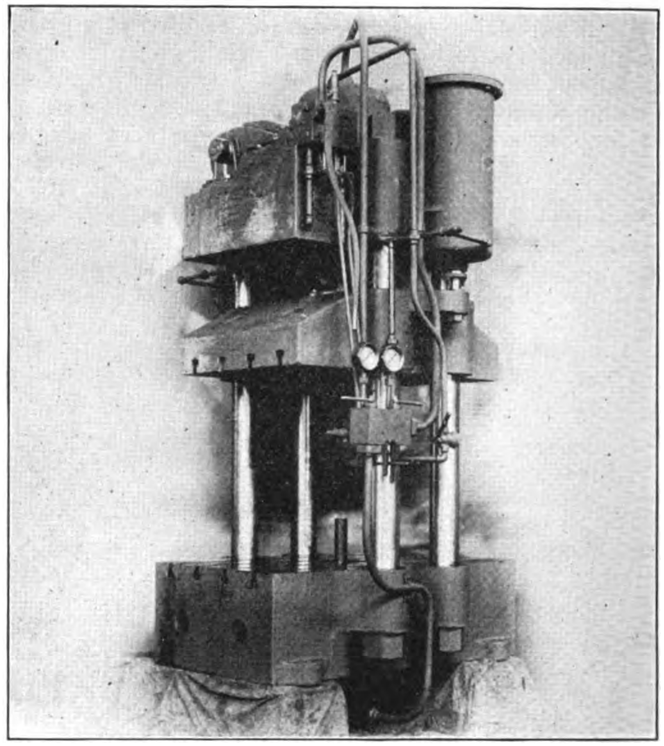
Testing a flanged tee.—Bulletin No. 2, recently issued by the Walworth Manufacturing Company, Boston, Mass., contains a complete description of a distortion test to a 4-in., 400-lb. working steam pressure, Walworth Sigma steel flanged tee made according to the American Engineering Standards Committee tentative standard dimensions. The tee was first submitted to an hydrostatic pressure test of 2,500 lb., after which the tee was fitted up with a 10-ft. length of 4-in. double extra-heavy pipe with a screwed steel flange on end, all of which was supported on 18-ft. centers. A total weight of 7,428 lb. was placed on the branch flange of the tee, which caused it to bend to the floor, or a total deflection of 27 1/16 in. The weight was removed permitting the pipe to spring back 4 3/16 in., leaving a permanent deflection of 22⅞ in. Finally the tee was again subjected to an hydrostatic pressure of 2,500 lb., which it withstood without any trouble.

Hydro-pneumatic press for railway shops

A SERIES of hydro-pneumatic presses designated as Model B, designed for railway shop use, have been placed on the market by the Chambersburg Engineering Company, Chambersburg, Pa. Exceptionally fast operation, complete accessibility of parts and ease of control enable these machines to meet the demands of the railway shop. The lighter presses are used for inserting and removing locomotive driving rod boxes and brasses, bushings, link hangers, bending and straightening levers and connecting rods, etc. The heavier capacity presses, one of which is illustrated herewith, are used for forming and pressing work in the steel car repair shop.

Fast operation is obtained by means of the hydro-pneumatic feature. The ram is brought down to the work by air pressure and the actual work is accomplished hydraulically under any pressure within the capacity of the machine. A large weighted pullback assures the fast return of the ram. The simplicity of the presses is achieved by mounting the motor, pump and crane on the top plates, thus giving free access to the press from all sides. The top plate also forms the water reservoir. The controlling valves are mounted on the side of the machines and so placed as to give the operator an unrestricted view of the work and the gages without changing his position.

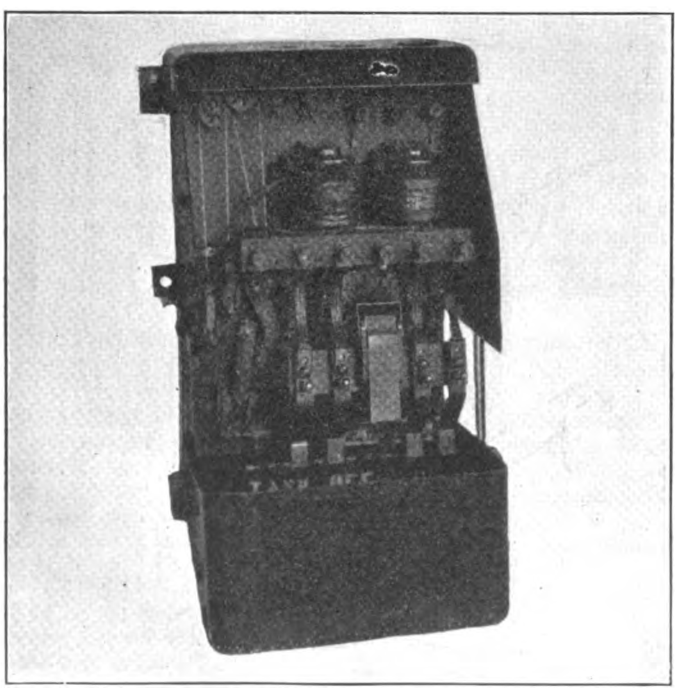
The machine shown in the illustration is a 300-ton, four-column press, provided with pneumatic pullbacks. Both the pressure ram and stripping ram advance rapidly to the work by pneumatic pressure, the actual work being completed by hydraulic pressure.



Chambersburg 300-ton hydro-pneumatic press

A push button starting switch

A PUSH button operated oil switch for starting squirrel cage induction motors directly across the line has recently been placed on the market by the Electric Controller & Manufacturing Company, Cleveland, Ohio. The device is known as the Type ZO starting switch and is controlled from one or more push button stations which may be located at convenient points. It is provided with four pairs of heavy contact fingers, three of which handle the main line in the case of three-phase or two-phase, three-wire motors, and the fourth pair handles the control circuit to the push button when the switch is arranged for no voltage protection. In the case of two-phase, four-wire switches all four lines are disconnected in the off position when the switch is wired for no-voltage release. When wired for no-voltage protection one line runs direct to the motor.



Push button operated oil switch for starting squirrel cage induction motors directly across the line

This switch uses an accurate inverse time element temperature overload device which consists of two alloy wires, each attached at one end to an adjusting screw and at the other end to a multiple lever which operates a quick make-and-break contact. The wire is connected across the secondary of a small current transformer. The gage of the expansion wire and the winding of the secondary of the transformer remain the same regardless of the horsepower ratings or voltage of the switch. The size of the wire and the number of turns of the primary is proportioned to suit the rating of the motor. An increase in current or an overload on the motor produces an increase in the current flowing in the secondary circuit, which causes the expansion wires to lengthen and, if the overload is severe enough or is of sufficient duration, the wires lengthen sufficiently to trip the overload relay contacts causing the starting switch to open and disconnect the motor from the line. The wires then cool and the overload relay contact automatically resets if a switch is wired for no-voltage protection. A

hand reset of the overload device by means of a small button projecting through the case is provided on switches arranged for no-voltage release.

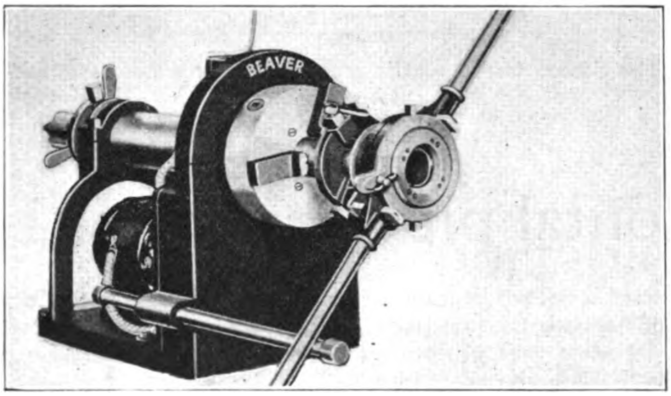
The overload device protects the motor against injury due to phase failure. If an attempt is made to start the motor with one phase open, the switch will open in less than five seconds, thus protecting the motor.

The oil tank will not leak as it is drawn from a single piece of sheet steel. The tank latches are arranged so that the tank can be lowered and left suspended to catch oil dripping from the contacts while the switch is being inspected. On account of the seepage of oil due to capillary attraction and from a slight splashing when the magnet surfaces engage, all moving parts of the switch are kept lubricated which protects the switch from corrosion when installed in corrosive atmospheres.

The switch is arranged for conduit connection and is of compact dimensions—13 in. high by 9 in. wide.

Portable power driven pipe threader

NO. 44 is the designation of a new portable electric machine recently placed on the market by the Borden Company, Warren, Ohio, for cutting and threading ¼-in. to 2-in. pipe, using any type or kind of hand operated die stocks or pipe cutters. A universal sliding extension shaft is furnished, however, to cut and thread up to 6-in. pipe, inclusive, using geared die stocks or cutters.



Borden portable power driven pipe threader with a capacity up to 6 in. inclusive

The operation of the machine is simple. The pipe is inserted and is rigidly held by a universal chuck. The die stock or pipe cutter is placed on the pipe as when cutting or threading by hand. The handle of the tool rests on a sliding bar at the side of the machine. When the current on, the pipe revolves while the tools stand still.

By using any type or kind of die stock or pipe cutter, this power drive virtually makes power machines of hand operated tools. It is also used to make up fittings in the machine, instead of by hand, thus performing a complete job of cutting, threading and fitting without removing the pipe from the machine.

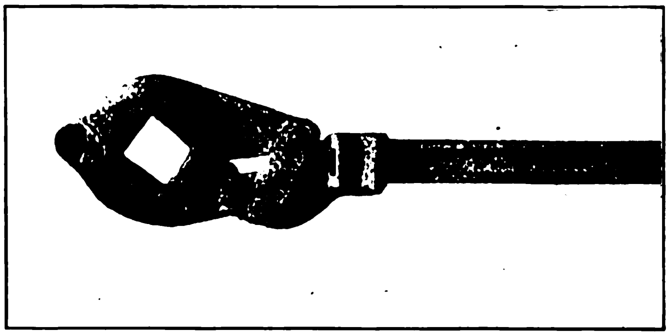
The machine is portable and weighs 230 lb. It is regularly equipped with a ½-hp. heavy duty, 110-220-volt, a.c., 60-cycle, single-phase motor and is operated from an ordinary light socket. Special motor equipment is available for localities where standard equipment is not suited.

Drop-bottom car door safety friction wrench

THE doors of hopper and drop-bottom cars are usually difficult to operate owing to the fact that they are subjected to considerable abuse in service. Consequently, much effort and time is required when dumping or winding up these doors. The Barrett Machine Company, Pittsburgh, Pa., has developed a wrench especially designed for this work, which it is claimed will function under all conditions with a minimum amount of effort and time.

The action of the wrench is secured through an arrangement of a toggle which gives a powerful tightening force in one direction only. The socket, which fits over the end of the car door shaft, is held between two straps which form the head of the wrench. These straps grip the socket when pressure is applied to the wrench handle. The toggle action insures instantaneous release so that the possible chance of the wrench injuring the operator by catching is reduced to a minimum. By the use of the toggle, there are no complicated parts to get out of order and no ball bearings, ratchet heads, pawls or triggers to catch.

No bolts are used in the wrench.



No bolts are used in the Barrett safety friction car door wrench

"Lanco" thread cutting die head

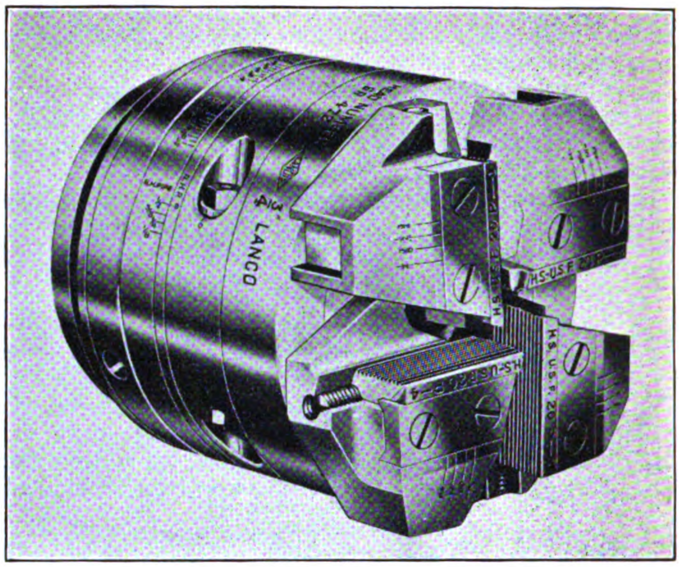
THE Landis Machine Company, Waynesboro, Pa., has placed on the market under the trade name of "Lanco" a new series of thread cutting die heads. The chasers are supported on the front face of the head, which permits easy access when it is necessary to remove them for grinding and when changing from one pitch to another.

The head is made of high carbon steel and is heat

treated throughout, and ground. This construction, together with the compact design of the head, reduces the wear to a minimum and prolongs the life. The head is adjusted to size by means of an adjusting worm. The adjusting worm is under the proper turning tension at all times, thereby eliminating the necessity of locking it for each adjustment of the die head for size. The graduated dial at the end of the adjusting worm gives a variation in adjustment of approximately .005 in. for each graduation. The head, when threading, is locked within itself by the engagement of two closing pins in hardened bushings. It is opened and closed automatically, which is always a desirable feature.

The head is graduated for all sizes of bolts, both right and left hand, and right hand pipe within its range. All passages and openings into the interior of the head are entirely covered under service conditions, making it impossible for dirt and chips to enter, thus prolonging the life of the head.

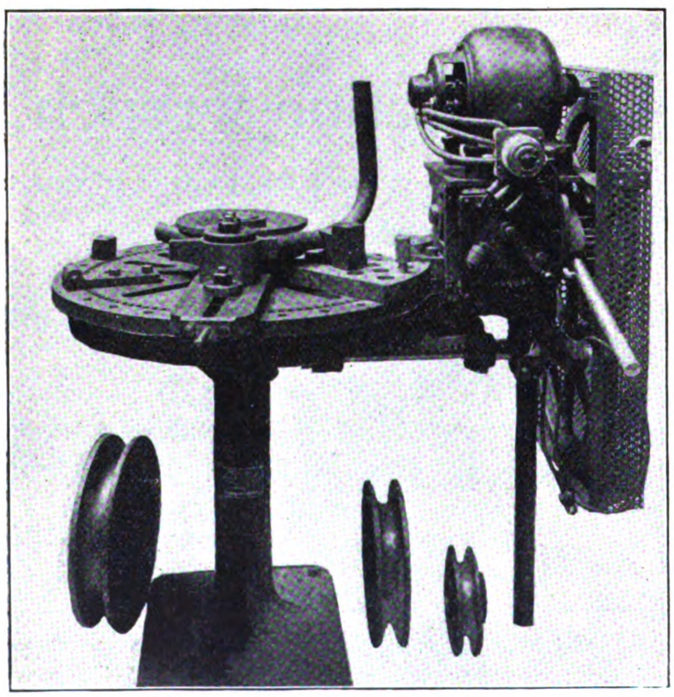
The head is made in the ⅜-in., 9/16-in., ¾-in., 1-in. and 1½-in. sizes. It is applicable to all makes of automatic, semi-automatic and hand operated threading machines.



The chasers can be readily removed from the Landis thread cutting die head

Motor driven horizontal pipe bender

HERETOFORE, the pipe benders manufactured by Pedrick Tool & Machine Company, Philadelphia, Pa., have been hand operated but since modern practice looks with more favor on power instead of hand work, this company is now building a pipe bender up to 2 in. in capacity which is especially designed for electric motor drive. A machine of this type is particularly adapted to railway work.



Power driven pipe bending machine with a capacity up to 2 in. inclusive

The face plate is geared to revolve within the cavity of the horizontal table so that the gear teeth are entirely covered and guarded. The bending roll, on the central stud, is bolted stationary and the bending arm, which moves with the face plate, bends the pipe around the roll. The other end of the pipe rests against a small saddle located on the resistance arm. This latter piece has a free radial movement which is held, wherever desired by a dowel pin in holes located in a circle around the face of the table.

This provides an important application because the bending arm and the resistance arm may be brought close together for the purpose of bending short pieces of pipe that have been cut off and, perhaps, threaded. A stop, which is bolted to the face plate, is provided so that any quantity of the same shape may be bent with the assurance that each piece is subjected to a uniform bending movement and consequently will register with the preceding bend when the stop makes contact with a pin suitably located in the holes spaced around the edge of the table.

From this it will be seen that from one size roll almost any shape may be obtained. The roll is grooved for the diameter of the pipe to be bent and governs the radius of the bend. The arc through which the face plate is turned, controls the degree or angle of bend. Hence, a right angle bend is made by revolving the face plate 90 deg., a larger or smaller angle is as easily made accordingly.

In the power driven machine the motor is allowed to run while the machine is in operation and the hand lever affords start, neutral and reverse positions instantly at the wish of the operator. The power drive serves a very useful purpose when quantities of the same shape are to be bent. It works at a uniform speed and without decreased production or the efficiency of the operator at the end of the day.

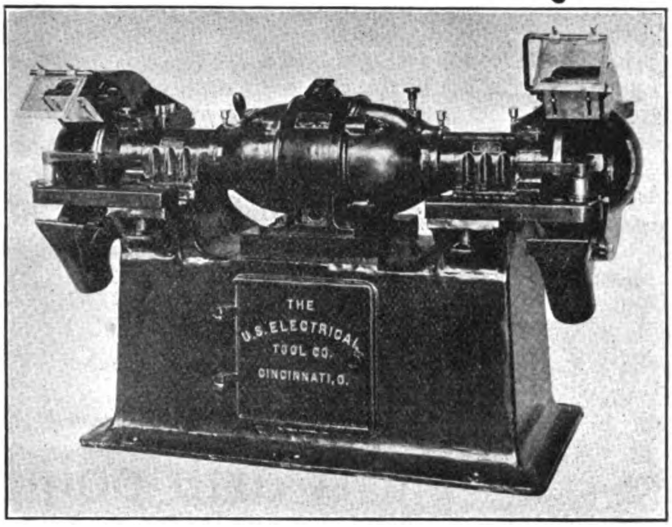
The horizontal table is convenient on which to handle, lay out and measure the work and also permits the bending of long pieces at the middle of the length which is often necessary in hand-rail work, running pipe lines, etc.

Besides the 2-in. power driven machine the manufacturer makes also a hand machine of the same capacity and smaller.

Heavy duty constant speed grinder

A HEAVY duty adjustable speed grinder, suitable for either alternating or direct current, has recently been placed on the market by the United States Electrical Tool Company, Cincinnati, Ohio. These grinders are so designed that the adjustment of the guards of the wheel will automatically regulate the speed of the motor so that the peripheral speed of the wheels is constant regardless of the wheel diameter. When used on direct current, constant peripheral speed can be obtained regardless of the wheel size.

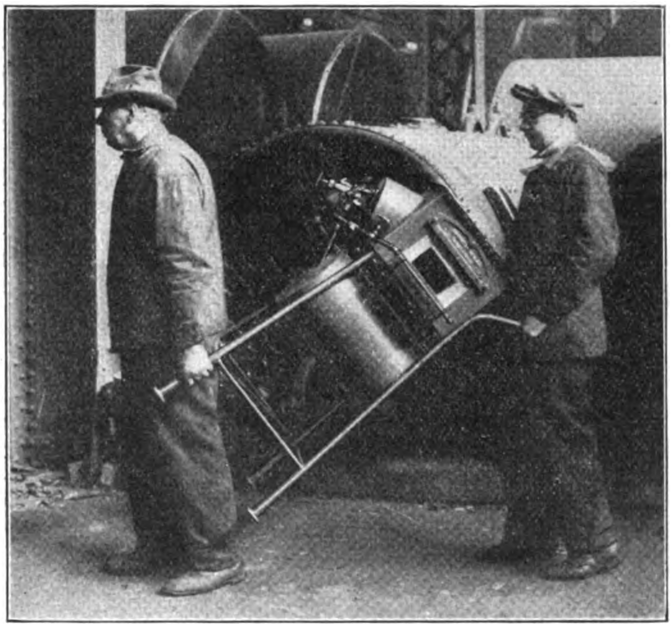
On alternating current, starting with a 24-in. wheel at 900 r.p.m., a periphery of approximately 5,500 ft. is obtained. The wheel can be used until it is worn to 18 in. at which time the next speed of 1,200 r.p.m. will automatically cut in by moving a hand lever which will then bring the periphery up to approximately 5,500 ft. Another change in speed occurs when the wheel is worn to 12 in. which increases the speed of the motor to 1,800 r.p.m. which will then again bring the speed up to approximately 5,500 ft. The alternating current motor on these machines is a three speed motor namely: 900, 1,200 and 1,800 r.p.m.



Constant speed grinder for use with alternating or direct current motors

Light portable oil rivet furnace

AN oil burning, hand portable rivet forge for shops and yards where a forge can be carried most conveniently, has been placed on the market by the Johnston Manufacturing Company, Minneapolis, Minn. It is equipped with the Johnston non-clogging vacuum oil burner, a description of which appeared on page 501 in the August, 1924, issue of the *Railway Mechanical Engineer*.



The Johnston oil rivet furnace can be carried by two men

The hearth of this forge is 40 in. above the floor so that the operator can see the rivets without stooping. The gases from the heating chamber are vented high enough so that they can not be blown by the wind against the workmen. The closed top chamber provides good combustion as the vent gases leave the bottom or coolest part of the heating chamber. The heating chamber is designed to give a rapid motion to the gases which come in contact with the rivets. This chamber is lined with standard sizes of fire brick and is made thicker at the points of maximum temperature. The frame is made of pipe and welded together which gives a minimum weight in proportion to the strength. It is also designed so that it can be readily carried from one job to another by two workmen.

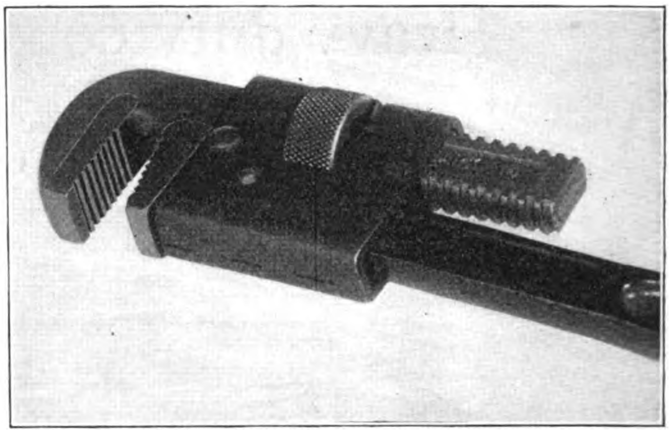
The furnace operates on compressed air between 60 to 125 lb. and burns either kerosene, distillate or fuel oil. It uses six cubic feet of air per minute and burns one gallon of fuel per hour. The fuel tank capacity is 7½ gal. per hour. The heating chamber is 8½ in. by 10 in. and its charging opening 5½ in. by 3½ in. It requires a floor space of 20 in. by 36 in. and weighs 240 lb.

All-steel pipe and monkey wrench

AN all-steel pipe and monkey wrench which has been introduced recently for use in railroad shops and enginehouses is illustrated. Features of this wrench are its construction of accurately machined drop forgings and the application of a removable lower wrench jaw held in place by a thumb screw. The construction is such that the lower jaw pivots slightly on the screw and this movement in conjunction with that of the hook jaw, gives a double action which assures an unusually rigid grip on round pipe or other similar material being turned against resistance. There is a noticeable tendency for the jaws to grip harder the harder the pull, and yet they re-

lease readily as soon as pressure is removed from the handle. Owing to the fact that in operation the jaws adjust themselves so as to be practically parallel, the tendency to crush the pipe is minimized. Another feature of this wrench is the absence of any handle or bridge springs to become lost or broken. The material and rugged construction of the frame are designed to give the wrench long life in the severe service to which wrenches are subjected in railroad shops and enginehouses.

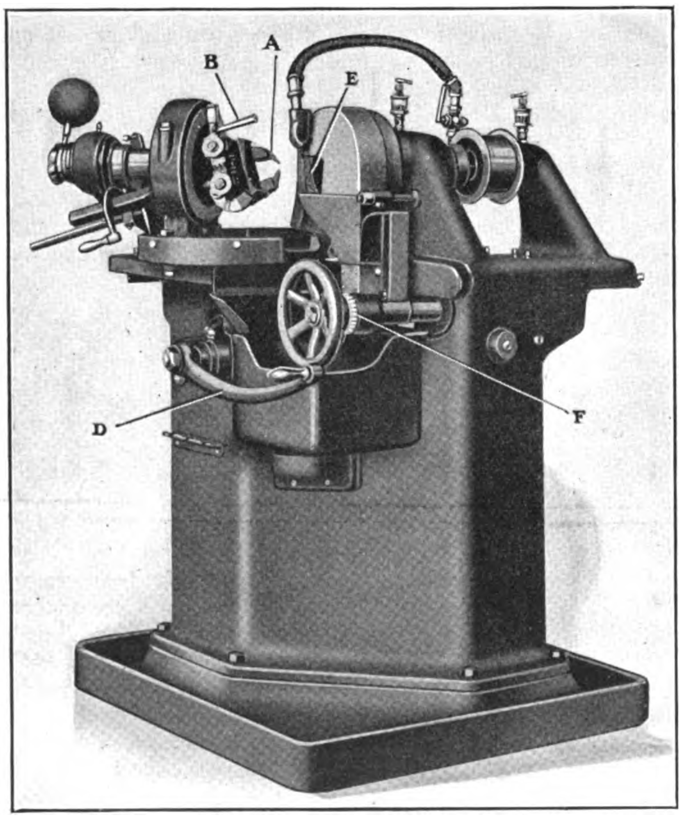
When used as a monkey wrench, the hook jaw is furnished without teeth and a plain inserted main jaw is also applied. For use on pipes, this wrench is provided in 8, 10, 14, 18, 24 and 36-in. sizes, the largest taking 3½-in. pipe. The monkey wrench sizes are 8, 10, 14 and 18-in. All parts of the monkey wrench are interchangeable with the pipe wrench. This wrench is made by the Larco Wrench & Manufacturing Corporation, Chicago.



Larco all-steel wrench with double-acting jaws

Twist drill point grinding machine

A TWIST drill point grinding machine built in two sizes, No. 2 taking drills ¼ in. to 7/4 in. in diameter, and No. 3 taking drills ⅝ in. to 2 in. in diameter, is now manufactured by the Union Twist Drill Company, Athol, Mass. It will sharpen points of twist drills having right-hand spiral flutes and two lips, and will grind them so that the cutting point will have lips that are the same length, with the chisel point coming at the center of drill.



Union twist drill point grinder which will sharpen all types of drills up to 2 in. in diameter

The drill is held by a two-jaw chuck *A*, operated by the lever handle *B*, which gives a rapid movement of the chuck jaws, thus taking a minimum amount of time in chucking the work. The chuck jaws are adjustable laterally so as to give them a clearance angle for different diameters of drills. A graduated plate on the upper jaw gives the setting for different diameters. The jaws can be adjusted vertically to obtain different clearance angles as required. The machine is adjusted, when assembled, to give a clearance angle of 12 deg.

The work spindle is carried in a housing that is adjustable to give various included angles of drill points ranging from 90 deg. to 118 deg. The machine is set to give a 118 deg. included angle of point which has been found to be most efficient for general work.

The work spindle housing is carried by a slide operated by the hand lever *D* so that the point of the drill is moved across the face of the grinding wheel. This slide travels on hardened and ground roller bearings, which permits rapid traverse with a minimum amount of effort on the part of the operator.

The chuck spindle front bearing is carried on hardened and ground steel rollers, and the rear bearing is carried in a bronze box adjustable for wear and adjustable longitudinally so that chuck and spindle can be kept in a correct position relative to the spindle boxes. The chuck spindle has a rotary movement of about 110 deg. and can be varied by setting adjustable screws.

The grinding wheel *E* is of the ring type, 8 in. in diameter, and is held by a flange clamped to the end of the wheel spindle. The wheel head has an adjustment of 4-in. to compensate for the wear of the wheel and allow for moving the wheel to the correct position in relation to the drill. A graduated collar *F* on an adjusting screw provides means for moving the wheel to the same position for grinding both lips of a drill.

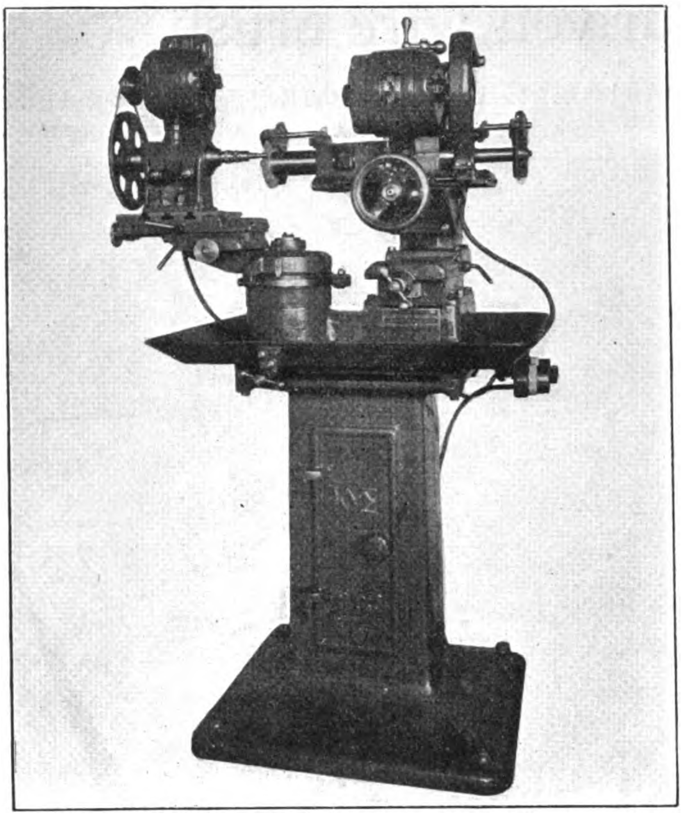
All drills, both high speed and carbon, should be ground wet with an ample supply of water on the work. A pump and tank with suitable piping is provided and supplies a sufficient flow of water to the wheel. The machine is equipped with suitable water or splash guards to protect the workmen.

A diamond holder is clamped in the chuck jaws in the same manner as a drill is clamped, and is traversed across the face of the wheel. This insures that the cutting face of the wheel is parallel with the travel of the drills when they are held in the chuck.

The countershaft has tight and loose pulleys 10 in. in diameter for a 3-in. belt and should run 550 r.p.m. The floor space required for the machine is 45 in. by 40 in. The net weight of No. 2 is 1,580 lb. and No. 3 1,850 lb.

Universal cutter and radius grinder

THE cutter and radius grinder illustrated has been placed on the market by the Keller Mechanical Engineering Corporation, Brooklyn, N. Y. The machine is intended for grinding milling cutters, reamers and similar tools, and is suited for spherical and radius, cylindrical, taper, face, angular form, flute and blade, clearance and back-off, internal and various surface operations.



Universal grinder especially adapted for shaping milling cutters

There are six separate movements on the machine, giving a wide range of adjustments and adaptability to many classes of work. It is possible to grind a desired radius on an end mill or on the corner of a face mill, at the same setting used for the rest of the grinding of the cutter.

The machine is self-contained, driven by two motors, one for the wheel drive and one for the work drive, and it has a spindle speed of 5,100 r.p.m. The ball-bearing wheel spindle is mounted on three slides, giving movement longitudinally, vertically and transversely of 4¾ in. each. The work-holding stretcher is mounted on a turntable so that it can be swung with relation to the wheel in order to grind the radius of the work. A cutter-grinding fixture is furnished for holding mills of all types, and for grinding the tracer points and similar work the cylindrical and face-grinding fixture, equipped with a motor, is provided. Five work speeds are adjusted to suit the work, by means of cone pulleys. The work table travel is 210 deg. angular, 3¾ in. radially and 1⅞ in. cross-slide. The size of the table is 6⅜ in. by 8½ in., and it is provided with three ½-in. tee-slots.

The cutter head can be tilted 45 deg. in either direction and the spindle of the work-holding attachment can be swiveled in a vertical plane and locked in any desired position. The wheels used are ⅜ in. by 4 in. and ⅛ in. by 4 in., either cup or saucer.

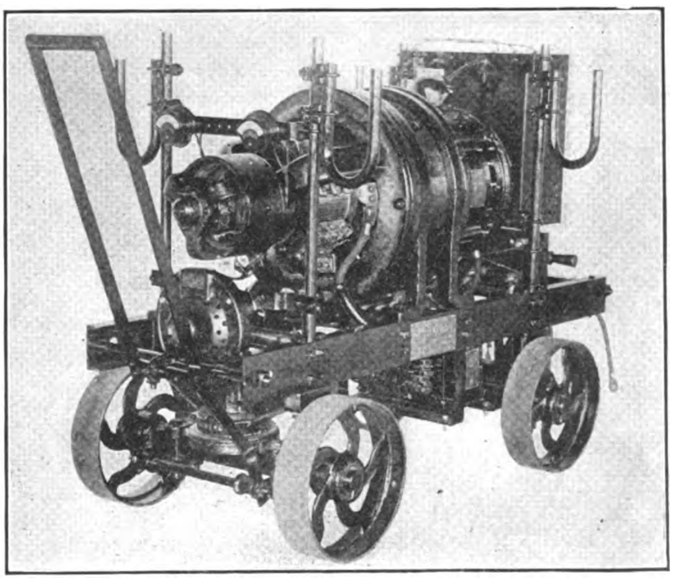
The overall height of the machine is 60 in., and the floor space required is 44 in. by 40 in., the net weight is 800 lb. and, crated for shipment, 875 lb.

Interpoles added to welding generator

THE USL welding generator, manufactured by the U. S. Light & Heat Corporation, Niagara Falls, N. Y., in 200 and 300 ampere capacities is a four-pole self- and separately-excited shunt machine with an all laminated magnetic structure. This type of construction permits a rapid change of magnetism so that the arc will respond quickly to the varying conditions and adjust itself to any demand. Each main pole is provided with two shunt field windings. One set of field coils receives current from a small exciter generator, while the other set is connected to the brushes of the welding generator. The effective flux is produced by the combined action of the self- and separately-excited fields.

In order to provide perfect commutation under severe service conditions the USL 300 ampere arc welder is equipped with four commutating poles. With the addition of these commutating poles perfectly black commutation at any load up to 350 amperes is assured. Maintenance cost and brush wear are therefore a minimum.

The feature of good commutation on machines with variable and fluctuating loads is of utmost importance in view of the fact that instantaneous inherent regulation is most effective on machines with smooth commutators. Another advantage gained through interpoles is the slight compounding action of the interpole flux which results in a steadier and more tenacious arc. This feature will be appreciated by all engineers experienced in the art and application of arc welding. The last advantage is the inherent arc current stabilizing action of the interpole



U. S. L. portable welding outfit

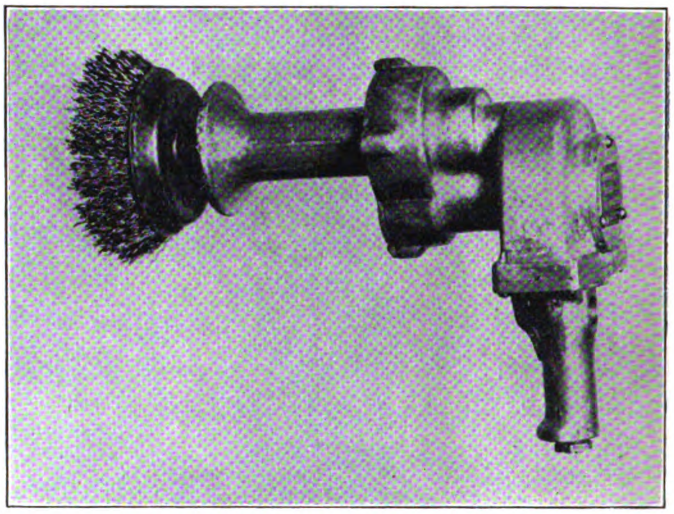
windings. As the interpole windings, being connected in series, always carry the full welding current, a very pronounced internal reactance is set up and to such an extent that under certain conditions the usual external stabilizer may be eliminated. This latter advantage is of decided importance in so far as a reduction in size or the entire elimination of the external reactance results in a higher over-all efficiency of the welding equipment.

Pneumatic turbine-driven wire brush

A PNEUMATIC turbine-driven cable brush for use in cleaning rust preparatory to painting tank and steel freight cars has been placed on the market by the Standard Turbine Corporation, Scio, N. Y. The turbine consists of a wheel operating at a speed of 12,000 r.p.m. mounted on ball bearings and geared to the low speed shaft driving the wire brush.

The low speed shaft is laid in a long sleeve bearing and arranged also with a ball thrust bearing to take up any thrust imposed in applying the brush. The air is admitted to the turbine wheel by means of a valve operated by a trigger. The turbine wheel itself consists of a small steel forging tested to a maximum speed of 100,000 r.p.m. The bearings are grease lubricated, the grease connections being arranged for the alemite system. The exhaust is through the center of the low speed shaft, which assists in keeping the brush clean.

The standing torque of the motor is claimed to be greater for equivalent air consumption than any reciprocating motor used for this kind of work. The no-load speed of the motor is always such as to be less than one-third of the tested safe speed of the wheel. The motor has an all aluminum casing and its total weight is 9¼ lb. without the brush and about 11 lb. with the brush. The motor is free from vibration.



Turbine driven wire brush for cleaning steel cars and tanks

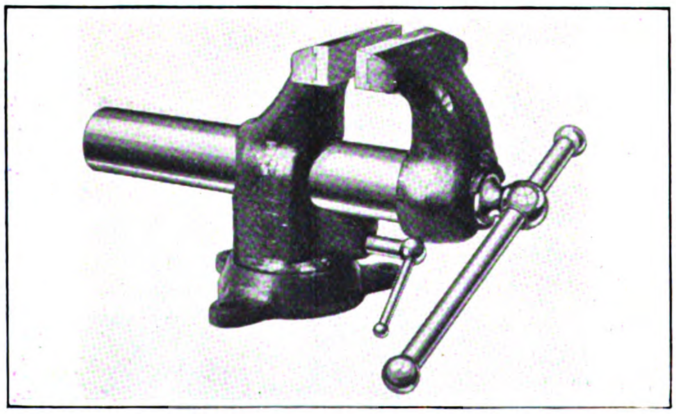
Steel drop forged bench vise

UNDER the trade name of "Dropfo," a vise that is made entirely of drop forgings, has recently been developed by the Fulton Drop Forge Company, Canal Fulton, Ohio. It contains no cast iron parts.

Each part is machined to be interchangeable with the same part on any other vise of the same size. The jaw plates are knurled and forged under the hammer and doweled onto the jaw. Thus, it is possible to replace the jaw plates, which are naturally subject to wear.

The vise is lighter in weight than the cast iron type. It is made with a swivel base and wedge lock that is quick to set and automatic in tightening up, and has a grip that is hard to shake or break loose.

It is made in four sizes: 3 in. with jaws opening 5½ in.; 4 in. with jaws opening 6 in.; 5 in. with jaws opening 8 in., and 5 in. heavy duty with jaws opening 8 in.



A bench vise made of steel drop forgings

Steel and its heat treatment.—The first of a series of articles on steel and its heat treatment, by H. M. Boylston, has been issued by the Republic Flow Meters Company, Chicago. This article gives the reasons for heat treatment; heating and cooling curves of pure iron showing the solidification temperature of iron and the critical temperatures, and inverse rate curves showing the critical temperatures of pure iron.

Portable electric twist drill grinder

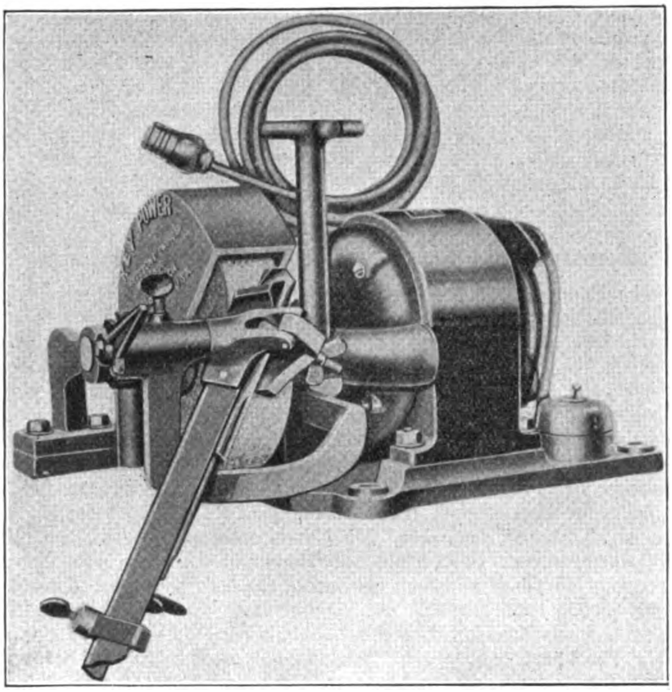
A NEW portable electric twist drill grinder has been designed to produce efficient work at a rapid rate with unskilled workmen. This device, called the "Key-power," is manufactured by the Keystone Grinder & Manufacturing Company, Pittsburgh, Pa.

The grinding action is produced by a light pressure of the drill against the face of the grinding wheel which permits rapid work and prevents burning of the steel or drawing the temper of the tool. The tool or drill is held firmly in place by means of a wedge-shaped toolholder that assures uniform results and eliminates the uncertainty of hand application. No water is necessary during the

grinding process since there is a continuous air circulation on the face of the wheel which contsantly keeps the tool cool.

Railroad repair shops and yards should find this device particularly useful due to its portability; the machine weighing only 60 lb. With it the tools can be ground on the job. A heavy hood over the grinding wheel gives ample protection to the operator.

This electric grinding device is driven by a Westinghouse ¼-hp. motor. An attachment cord enables the machine to be plugged into any ordinary socket. It is capable of redressing all shapes and kinds of edged tools and is fitted for grinding ¼-in. to 1½-in. drills.



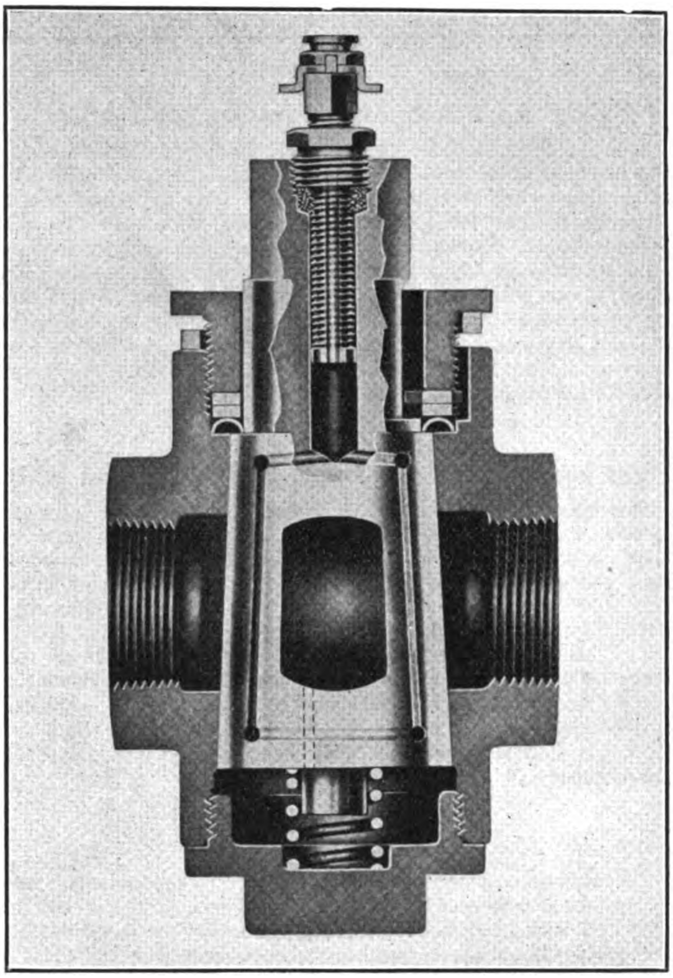
Portable electric twist drill grinder which can be operated by an unskilled workman

Lubricated plug valve

MODIFICATION of a plug valve which was first described on page 1415, in the June 11, 1924, Daily Railway Age, specially designed for steam, air, water, gasoline, kerosene and fuel oil lines in coach yards, general repair shops, enginehouses and terminals, has recently been placed on the market by the Barco Manufacturing Company, Chicago. One-quarter of a turn gives a full pipe area opening through the valve. Since no valve stem is used packing maintenance and sprung or bent stems are eliminated.

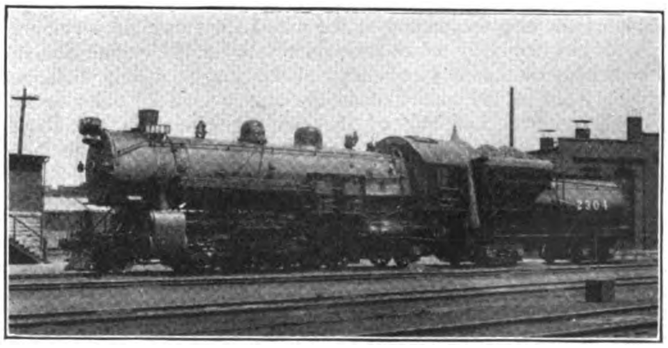
The valve is provided with a grease reservoir and lubricating passage ways, as indicated in the accompanying illustration. A lubricator is provided in the plug which prevents the escape of the grease and provides the feeding of the grease to the surfaces of the valve as required. Owing to this feature, the plug and plug seat hold the pressure tight, and the valve operates with ease. The fact that the valve and seat are lubricated at all times greatly reduces wear and replacement. The lubricant may be purchased in tubes ready for use which is usually applied by means of a Barco lubricating gun. If, however, a gun is not available, the grease may be rolled in candle form and applied by hand, after first removing the lubricator.

The valves are ordinarily furnished with handles or wrenches, or they may be operated with an ordinary monkey wrench. If wrenches are desired, they may be obtained in either the standard wrench or the cross wrench. The latter is furnished for valves that are placed in overhead lines, so that they may be operated from below by a slight pull on the opening or closing chains attached to the ends of the handle.



Barco Type AC1 lubricated plug valve which opens fully with one quarter turn

The Type AC1, which is illustrated, will carry the following pressures: Steam, 150 lb.; water, 300 lb.; air, 150 lb. The temperature must not exceed 400 deg. F.



Union Pacific locomotive No. 2304 ready to leave the enginehouse, Cheyenne, Wyo.

General News

Safety Appliance Act—defective hand brake

A brakeman took hold of the wheel of a hand brake to help him to climb to the top of the car to release the brake, when the brake, due to a defect, became loose and spun the wheel round, throwing him to the ground. The Circuit Court of Appeals, Second Circuit, holds that if the brake was incidentally used in going to the point where it was to be released by turning the hana wheel, it was within section 2 of the Safety Appliance Act requiring efficient hand brakes on cars, and the fact that the brakeman was not then using the brake for the purpose for which it was intended did not defeat his right to recover.—Lehigh Valley v. Howell, 6 Fed. *2d*) 784.

Large equipment orders placed by N. Y. C. and M. P.

The New York Central has ordered 4,500 freight cars as follows: 2,000 box from the American Car & Foundry Company; 1,000 gondola from the Pullman Car & Manufacturing Corporation; 500 gondola from the Illinois Car & Manufacturing Company; 500 gondola from the General American Car Company; and 500 gondola from the Standard Tank Car Company.

The Missouri Pacific has ordered 3,000 freight cars as follows: 1,000 box, 250 hopper and 250 furniture from the American Car & Foundry Company; 500 box from the General American Car Company; 500 box and 250 automobile from the Standard Tank Car Company; and 250 stock from the Pennsylvania Tank Car Company.

Cost of locomotive fuel

The average cost of coal used as fuel for road locomotives and charged to operating expenses in August was $2.66 per ton, as compared with $2.95 in August, 1924, according to the Interstate Commerce Commission's monthly statement, covering 159 Class 1 railways, excluding switching and terminal companies and switching locomotives. Fuel oil, however, cost 3.23 cents per gallon as against 2.86 cents last August and the total cost of coal and fuel oil for the month was $26,305,785 as compared with $26,375,435 last August. For the eight months ended with August 31 the total cost of coal and fuel oil was $214,736,375, as against $237,750,593 last year, a saving of approximately $28,000,000 in coal being offset in part by an increase of approximately $5,000,000 in fuel oil.

Record run by oil-electric rail car

On November 4 one of the new oil electric cars of the Canadian National completed a run from Montreal, Que., to Vancouver, B. C., a distance of 2,937 miles in 67 hours. This is the fastest time on record for the run between these points and during the whole of the trip the engine of the car did not once stop running.

Arranged primarily as an endurance test for the engine, the run proved also the speed possibilities of the car over long distances. At one point in Western Canada the car covered 22 miles in less than 22 minutes and one of the steepest grades in the Rocky mountains was climbed at an average speed of 40 miles an hour. The average speed for the entire trip was slightly under 44 miles per hour. This car was described in the November *Railway Mechanical Engineer*.

Wage statistics for August

A summary of the reports of Class I railroads to the Interstate Commerce Commission indicates that the number of railroad employees and the total compensation were greater in August, 1925, than in any month since October, 1924. The total number of employees was 1,800,219, an increase of 4,550 or 0.3 per cent over the returns for the previous month. The total compensation increased $1,371,967 or 0.6 per cent. Compared with August last year there was an increase of 0.6 per cent, while the total compensation increased 3.2 per cent. The percentage difference between the employment and compensation is due to an increase in the number of hours worked per employee coupled with an increase of 0.6 cents in the straight time hourly earnings and 1.5 cents in the overtime earnings.

Pennsylvania announces fuel contest winners

The Pennsylvania has just announced the winners of the highly successful contest for the best paper on fuel conservation which closed last month. There were 75 entrants in the contest, which was open to locomotive enginemen and firemen employed in any one of the three regions of the Pennsylvania. The contest was close in all regions and the committee which had charge of selecting the winners reported that it was difficult to make their decision because all of the papers were interesting, well-written and gave evidence of study and interest in the subject. There were three winners in each region, those in the Eastern region being first, R. H. Thomson, engineer, Maryland division; second, H. P. McLane, fireman, Philadelphia division; and third, J. W. West, fireman, Maryland division. In the Central region the winners were first, John Bruce, Sr., engineman, Panhandle division; second, F. L. Lievig, engineman, Pittsburgh division, and third, C. F. Lockhart, engineman, Pittsburgh division. The winners in the Western region were first, R. W. Karns, engineman, Cincinnati division; second, G. R. Cooper, fireman, Cincinnati division, and third, N. A. Gibson, engineman, Indianapolis division.

American built locomotives popular in South Africa

Record crops this year have found the South African Railways so inadequately equipped with rolling stock and motive power that some of the expresses running between Johannesburg and the coast have had to be temporarily suspended, and the big Baldwin engines recently making new records for the 1,000 miles run have been transferred to the fast freight service, says the Johannesburg correspondent of the Times (London) Trade Supplement. In the effort to relieve the shortage 15 additional locomotives have been ordered from the Baldwin Locomotive Works. Of these 15 new locomotives ten are to be of the Mountain type and five of the Pacific type.

Two of each of these types have been running on the South African Railways for over a month. They were ordered by the Administration on December 15 last. As far as is consistent with South African conditions these locomotives embody the latest American practice.

With the order for the 15 additional locomotives in course of construction at Philadelphia, the Baldwin Locomotive Works will have supplied 79 locomotives to the South African Railways. The first order was placed in 1892. The railways have now 1,862 locomotives and 34,362 cars, an increase since 1909 of 451 locomotives and 11,795 wagons. A total of 54 locomotives are on order, and every month will witness a substantial increase in the capacity of the system for handling the huge traffic with which it now has to cope.

Meetings and Conventions

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs.

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—C. Borcherdt, 202 North Hamlin Ave., Chicago.

AMERICAN RAILWAY ASSOCIATION, DIVISION V.—MECHANICAL—V. R. Hawthorne, 431 South Dearborn St., Chicago. Next meeting June 9-16, inclusive, Young's Million Dollar Pier, Atlantic City, N. J.

DIVISION V.—EQUIPMENT PAINTING SECTION.—V. R. Hawthorne, Chicago.

DIVISION VI.—PURCHASES AND STORES.—W. J. Farrell, 30 Vesey St., New York. Next meeting, June 9, 10 and 11, Atlantic City.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—G. G. Macina, 11402 Calumet Ave., Chicago.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Calvin W. Rice, 29 W. Thirty-ninth St., New York. Railroad Division, Marion B. Richardson, 30 Church St., New York.

AMERICAN SOCIETY FOR STEEL TREATING.—W. H. Eiseman, 4600 Prospect Ave., Cleveland, Ohio.

AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago, Ill.

CANADIAN RAILWAY CLUB.—C. R. Crook, 129 Charron St., Montreal, Que. Regular meetings second Tuesday in each month, except June, July and August, at Windsor Hotel, Montreal, Que. Next meeting, December 8. Paper on inspection of material for railway purposes will be presented by R. Job, vice-president, Milton Husey Co., Montreal.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 N. Pine Ave., Chicago, Ill. Meeting second Monday in month, except June, July and August, Great Northern Hotel, Chicago, Ill.

CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—R. E. Giger, 721 North 23rd St., E. St. Louis, Ill. Meetings, first Tuesday in month, except June, July and August, at the American Hotel Annex, St. Louis.

CAR FOREMEN'S CLUB OF LOS ANGELES.—J. W. Krause, 514 East Eighth St., Los Angeles, Cal. Meeting second Friday of each month in the Pacific Electric Club Building, Los Angeles, Cal.

CENTRAL RAILWAY CLUB.—H. D. Vought, 26 Courtlandt St., New York, N. Y. Regular meetings, second Thursday each month, except June, July and August. Hotel Statler, Buffalo, N. Y. Next meeting December 3. Paper on best means of promoting friendly relations between the public and railroads will be presented by Harry F. Burber, plant manager, National Aniline Company, Buffalo. G. C. Woodruff, assistant freight manager, New York Central, Buffalo, will handle the subject from the viewpoint of a railroad traffic officer and R. E. Woodruff, superintendent, Erie, Buffalo, from that of a railroad operating officer.

CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—A. S. Sternberg, Belt Railway, Clearing Station, Chicago.

CINCINNATI RAILWAY CLUB.—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meetings, second Tuesday, February, May, September and November.

CLEVELAND STEAM RAILWAY CLUB.—F. L. Frericks, 14416 Adler Ave., Cleveland, Ohio. Meetings first Monday each month except July, August and September, at Hotel Cleveland, Public Square, Cleveland. Next meeting December 7. Paper on the value of man power will be presented by S. F. Fannon, Sherman Service, Inc.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—W. J. Mayer, Michigan Central, 2347 Clark Ave., Detroit, Mich.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. B. Hutchison, 1809 Capitol Ave., Omaha, Neb. Next meeting May 11-14, 1926, Hotel Sherman, Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabash Ave., Winona, Minn.

MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 26 Courtlandt St., New York. Next meeting May 25-28, 1926, Hotel Statler, Buffalo, N. Y.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meeting second Tuesday in month, except June, July, August and September. Copley-Plaza Hotel, Boston, Mass. Next meeting December 8. Paper on comparative merit of steam and electricity in railroad operation will be presented by L. K. Sillcox, general superintendent of motive power, Chicago, Milwaukee & St. Paul.

NEW YORK RAILROAD CLUB.—H. D. Vought, 26 Courtlandt St., New York. Meeting third Friday in each month, except June, July and August, at 29 West Thirty-ninth St., New York.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgreb, 625 Brisbane Building, Buffalo, N. Y. Regular meetings, January, March, May, September and October.

PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Regular meetings, second Thursday of each month in San Francisco and Oakland, Cal., alternately.

RAILWAY CLUB OF GREENVILLE.—F. D. Castor, castor, maintenance of way department, Bessemer & Lake Erie, Greenville, Pa. Meeting last Friday of each month, except June, July and August.

RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Regular meeting fourth Thursday in month, except June, July and August. Fort Pitt Hotel, Pittsburgh, Pa.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, second Friday in each month, except June, July and August. Next meeting December 11. Papers on the general subject of railroads will be presented by James C. Davis, director general of railroads, and by C. C. Cook, chairman of the Committee on Economics of Railway Labor of the A. R. E. A. Christmas entertainment.

SOUTHEASTERN CARMEN'S INTERCHANGE ASSOCIATION.—J. E. Rubley, Southern Railway shops, Atlanta, Ga.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, 1177 East Ninety-eighth St., Cleveland, Ohio.

WESTERN RAILWAY CLUB.—Bruce V. Crandall, 226 W. Jackson Blvd., Chicago. Regular meetings, third Monday in each month, except June, July and August.

Purchases and Stores meeting

The 1926 annual meeting of Division VI—Purchases and Stores, American Railway Association, will be held at Atlantic City, N. J., on June 9, 10 and 11, coinciding with the first three days of the meeting of Division V—Mechanical. The headquarters of the Purchases and Stores Division will be announced later.

Supply Trade Notes

William Jarvis Wickes, president of the United States Graphite Company, Saginaw, Mich., died on November 1, from heart trouble.

F. S. Hartwell has been appointed representative of the Davis Boring Tool Company, St. Louis, Mo., with headquarters at Rochester, N. Y.

Charles B. Ashmead has been appointed sales representative of S. F. Bowser & Co., Inc., Ft. Wayne, Ind., with headquarters at Cleveland, O.

Edward E. Roberts will in future represent, in the western part of New York state, the Firth-Sterling Steel Company, McKeesport, Pa.

Homer D. Williams, president of the Carnegie Steel Company, Pittsburgh, Pa., has resigned to become president of the Pittsburgh Steel Company.

E. K. Conneely, vice-president of the New York Air Brake Company, at New York, has resigned to become vice-president of the Pullman Company.

The Goodell Pratt Company, Greenfield, Mass., has purchased the portable electric drill business of the A. F. Way Company, Inc., East Hartford, Conn.

The Link-Belt Company, Chicago, has awarded a contract to the H. K. Ferguson Company, Cleveland, O., for a one-story, 120 by 260 ft. addition to its plant.

The Sullivan Machinery Company has moved its Sydney, New South Wales, office from Australasia Chambers, 3 Martin Place, to the Kembla building, Margaret street.

Stewart A. Davis, vice-president of the American Sheet & Tin Plate Company, Pittsburgh, Pa., died unexpectedly on November 5, in his home at Pittsburgh, at the age of 58.

Page & Ludwick, Chicago, have been appointed representatives in Illinois for the Magnetic Manufacturing Company, Milwaukee, Wis., and the Thomas Flexible Coupling Company, Warren, Ohio.

James A. Galligan has joined the sales department of the Union Railway Equipment Company, Chicago. Mr. Galligan was formerly vice-president of the Mortimer B. Flynn Coal Company of Chicago.

F. W. Stubbs, formerly mechanical engineer of the Chicago Great Western, has been appointed railroad representative of the A. M. Byers Company, Pittsburgh, Pa. Mr. Stubbs will be located in Chicago.

Browning has been elected vice-president in charge of sales activities and J. A. Rafferty, vice-president in charge of engineering, manufacturing and research.

M. J. Carney, president of the Prest-O-Lite Co. Inc., New York, has been elected chairman of the board; William F. Barrett, vice-president, has been elected president; Ralph R. Browning has been elected vice-president in charge of acetylene sales activities and R. J. Hoffman, has been re-elected vice-president in charge of storage battery and automotive divisions.

Ward G. Day, for the past seven years in charge of the service department of Fairmont Railway Motors, Inc., at Fairmont, Minn., has been promoted to special agent, with headquarters at New Orleans, La. Mr. Day's jurisdiction will cover the states of Texas, Louisiana, Mississippi, Alabama, Arkansas, Georgia and Florida. Carl Brhel has succeeded Mr. Day at Fairmont.

Henry J. Barnes has been elected vice-president of the Alumino-Thermic Corporation, Roselle Park, N. J. Mr. Barnes has been connected with the Alumino-Thermic Corporation for the past three years. Previous to that time he was for many years in the sales department of the Metal & Thermit Corporation, at the time of his resignation being district manager in charge of Canada.

William G. Clyde, senior vice-president and general manager of sales of the Carnegie Steel Company, Pittsburgh, Pa., has been elected president. Mr. Clyde was born in Chester, Pa., he attended the public schools of Chester and later entered the Pennsylvania Military College graduating with the class of 1888. He began work as civil engineer with Ryan & McDonald, constructors, of Baltimore, Md., and later became associated with Robert Wetherill & Co., machinists and founders of Chester. Mr. Clyde began his mill training with the Wellman Steel & Iron Company at Thurlow, Pa., as superintendent of the plate mills. subsequently going to the Illinois Steel Company, at South Chicago, where he remained for six years. He was then appointed sales manager for the American Steel Hoop Company at Philadelphia, remaining in that position until this firm was taken over by the Carnegie Steel Company. After serving three years in sales work at the Cleveland office Mr. Clyde was appointed assistant general sales manager of the Carnegie Steel Company, with headquarters at Pittsburgh, and in March, 1918, he was made vice-president and general manager of sales of this company.

W. G. Clyde

Four General Electric Company men were killed and two were injured in the train wreck which occurred on the Pennsylvania Railroad near Plainsboro, N. J., on November 12. The dead include R. D. Reed, a member of the General Electric industrial department and in charge of the sale of electric arc welding equipment; Mark A. Atuesta and Arthur W. Gross, members of the manufacturing department, and John C. Horstman of the manager's staff at the Schenectady plant. Among the injured were D. H. Deyoe of the industrial engineering department of the

company and Thomas Wry of the Lynn River works. All the men had met in Baltimore in connection with the Inter-works welding committee of the General Electric Company and were en route to the Bloomfield plant when the accident occurred.

J. H. Whiting, president and treasurer of the Whiting Corporation, Harvey, Ill., has been elected chairman of the board. Col. T. S. Hammond, who for many years has been vice-president and secretary, succeeds Mr. Whiting as president and treasurer. R. A. Pascoe succeeds Col. Hammond as secretary. R. H. Bourne succeeds Col. T. S. Hammond as president of the Grindle Fuel Equipment Company, a subsidiary of the Whiting Corporation, continuing also as vice-president and sales manager of the Whiting Corporation. N. S. Lawrence, vice-president and assistant sales manager of the Whiting Corporation, is also president of the Swenson Evaporator Company, another subsidiary of the Whiting Corporation. J. H. Whiting will remain actively engaged in the business, and no change of policy is involved on the part of the Whiting Corporation and its two subsidiaries.

Benjamin B. Greer, chief operating officer of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago, has resigned. Mr. Greer has been elected president and a director of the New York Air Brake Company, New York, to succeed Charles A. Starbuck, who died on May 29. Mr. Greer was born on August 6, 1877, at Chicago, and began his business career with the Pullman Company in the summer of 1899. A few months later he entered the service of the Great Northern at St. Paul, Minn., as a clerk in the accounting department, after which he was successively material clerk in the superintendent's office, extra gang foreman, assistant roadmaster, chief clerk to the division superintendent and assistant superintendent, with headquarters at Minneapolis, Minn. Mr. Greer left the Great Northern in December, 1908, to become transportation inspector on the Chicago, Burlington & Quincy, with office at Chicago. He was promoted in 1910 to superintendent of the St. Louis terminal. In May, 1911, he became superintendent of the Hannibal division, and in January, 1912, was transferred to the St. Joseph division. In 1913, he was promoted to assistant to the general manager of the Lines East of the Missouri River, with headquarters at Chicago, and the following year he became assistant general manager of the Lines East. From 1915 to July, 1916, he was assistant general manager of the Lines West and then became assistant to the vice-president in charge of operation, which position he held until September, 1917, when he was elected vice-president and general manager of the Colorado & Southern. In November, 1917, he was also elected president of the Colorado Springs & Cripple Creek, with office at Denver, Colo., resigning these positions later in that year, to become assistant regional director of the Central Western region. In November, 1919, he was appointed federal manager of the Chicago, Milwaukee & St. Paul, the Ontonagon and the Escanaba & Lake Superior. On the termination of federal control in February, 1920, he became vice-president in charge of operation of the Chicago, Milwaukee & St. Paul, and subsequently served under the receivership as chief operating officer.

B. B. Greer

The Yates-American Machine Company has been organized through the consolidation of the P. B. Yates Machine Company, Beloit, Wis., and the American Woodworking Machine Company, Rochester, N. Y. J. E. McKelvey, president of the American Woodworking Machine Company, and P. G. Farrow, vice-president and general manager, C. E. McQurston, treasurer, and F. R. Smith, secretary, of the P. B. Yates Machine Company, will retain their respective positions in the new company. H. A. Von Oven, one of the trustees of the P. B. Yates Machine Company, who has been acting president since the death of P. B. Yates, has resigned.

Trade Publications

G-E flow meters.—Electrically operated flow meters for measuring steam, water, oil, gas, etc., are illustrated in a four-page bulletin issued by the General Electric Company, Schenectady, N. Y.

Electric tramrails.—"Mr. Keen Kompetitor" is the title of a brochure being issued by the Cleveland Electric Tramrail Company, Wickliffe, Ohio, showing the electric tramrail as it is used in various industrial shops for the moving of heavy loads.

Fire brick cement.—The uses of Adamant firebrick cement in the building of natural gas-fired boiler and oil-burning welding furnaces and in the furnaces of a mill and lumber company are described in three illustrated folders issued by the Botfield Refractories Company, Philadelphia, Pa.

Daily record chart.—A full-size reproduction of the daily record chart produced by the Twin Type meter has been issued in folder form by the Esterline-Angus Company, Indianapolis, Ind. The Twin Type meter elements are the same as those used in single meters, but two records, synchronized as to time, are produced on one chart.

Steel taped cable.—"The story of steel taped cable" is the title of a 24-page booklet issued by the Okonite Company, Passaic, N. J. The construction of the steel taped cable is shown in detail in this booklet, and a few of the manifold uses to which it may be put are pictured. Specifications and tables for cables of various voltages also are given.

Forging machinery.—A 10½-in. by 13½-in. book containing 20 pages of illustrated matter descriptive of the second exposition of National forging machinery recently held at Tiffin, Ohio, has been prepared by the National Machinery Company, Tiffin. This book is intended to bring the exposition to those who were unable to attend, and shows the progress in National machine forging equipment.

Wall chart of tool steels.—A 12-in. by 18-in. wall chart descriptive of the various grades of Vasco tool steels, the purpose for which each grade is particularly adapted, the proper heat treatment, etc., is being distributed by the Vanadium Alloys Steel Company, Latrobe, Pa., to toolroom foremen, master blacksmiths, purchasing agents and other mechanical executives interested in this tool steel.

Texrope drive.—Bulletin No. 1228, entitled "Allis Texrope Drive," has been issued by the Allis-Chalmers Manufacturing Company, Milwaukee, Wis. After a brief summation of the advantages of the Texrope drive, its application is described and a graph for determining sheave diameter or distance between centers given. The method to be followed in laying out an Allis Texrope drive is then explained.

Grinding machinery.—Bulletins Nos. 84, 100, 120 and 174, descriptive of heavy duty face grinders, radial grinders, motor-driven buffing lathes and motor-driven floor grinders, respectively, have been issued by the Bridgeport Safety Emery Wheel Company, Bridgeport, Conn. The face grinder with a 32-in. sectional grinding wheel is designed for grinding guide bars and flat surfaces; the floor grinders and buffing lathes are of the heavy duty series, and the radial grinders are without belts, countershafts, or overhead suspension and operate in or out, up or down, on horizontal surfaces or surfaces at any angle and completely around their bases.

Bridgeport brass.—In commemoration of its sixtieth anniversary, the Bridgeport Brass Company, Bridgeport, Conn., has had reprinted and is distributing in pamphlet form an account of its development from 1865 up to the present day. Following an outline of the personnel of the company in 1865, the first American micrometer as it was originated in the shop of the Bridgeport Brass Company is described, and its subsequent development illustrated. Interesting references are made to the early use of brass in hoop skirts, clock parts, lanterns, telephone parts, condenser tubes, trolley wires, etc. The facilities now used in the Bridgeport shops for the production of sheet brass from copper and zinc are then pictured and several of the operations described.

Personal Mention

General

James Paul has been appointed assistant superintendent of motive power of the Atlantic Coast Line, with headquarters at the Uceta shops, Tampa, Fla., in charge of mechanical forces on the third division, and reporting to the superintendent of motive power, at Waycross, Ga.
